Preface

Isolation and Identification of Drugs was first published in 1969 from an idea developed by Professor E. G. C. Clarke, who edited that first edition. Regrettably, Professor Clarke did not live to see the inception of a new edition. It seemed fitting, therefore, to call this new edition Clarke's Isolation and Identification of Drugs, especially as the book is affectionately known as 'Clarke'.

The first edition became a standard reference text for those concerned with the identification of drugs, gaining its reputation by providing a dependable source of analytical data for drugs and allied substances. The dog-eared, stained copies on laboratory benches are a testament to its usefulness. Accidental or suicidal poisoning, the abuse of narcotics and other drugs, the dangerous habit of glue-sniffing, and drug abuse in sport have increased enormously during recent years. The information in this book has been planned to provide the means for detecting, identifying, and quantifying most drugs and other toxic substances which are likely to be encountered in these situations, and to assist in interpreting the analytical results.

The book was planned for use not only in hospital and toxicological laboratories, but also in numerous other analytical establishments—including hospital and industrial quality control laboratories, and clinical laboratories engaged in drug investigations for purposes such as therapeutic drug monitoring or research into pharmacokinetics and patterns of drug metabolism. Also, there is much information which will be of use in certain areas of environmental toxicology, particularly the analysis of toxic metals and pesticides. Finally, the needs of students who are studying drug analysis and its applications have been kept in mind during the writing of the book.

There have been many developments in analytical techniques since the first edition was published, and this has necessitated rewriting the whole of the text and the inclusion of new data throughout. Nevertheless, the style and presentation used in the first edition have been retained.

The amount of text in the book has been increased by about 60% which has been made possible by increasing the page size and using a double column format throughout. Whenever possible, the data

have been verified from at least one independent source.

The book is divided into four parts.

Part 1: Analytical Techniques

This part contains 18 chapters on analytical techniques and allied subjects. New chapters in this edition include descriptions of hospital toxicology and drug abuse screening, forensic toxicology, drug abuse in sport, therapeutic drug monitoring, the analysis of metals and anions, and the analysis of pesticides, together with information on sampling procedures and on the use of quality control in clinical analysis.

The information on analytical techniques has been extended and brought up to date, particularly with the inclusion of high pressure liquid chromatography, fluorescence spectrophotometry, and nuclear magnetic resonance spectroscopy. Each chapter provides a description of the technique, practical hints on its use, and information on the application of the technique to problems.

The chromatographic systems have been completely revised and made more comprehensive and systematic. The general screening system using thin-layer chromatography has been extended and, for the first time, general screening systems employing gas chromatography and high pressure liquid chromatography are described. The information on colour tests has been completely revised and extended. The older methods of paper chromatography and microcrystalline tests have been omitted from this edition. A final chapter brings together the knowledge of pharmacokinetics and drug metabolism which is needed for the interpretation of the qualitative and quantitative results obtained from the analyses.

Part 2: Analytical and Toxicological Data

This part contains monographs for over 1300 drugs and related substances. About 160 substances which were included in the first edition, but which are now of little interest, have been deleted (see p. xvii). However, about 300 substances not described previously have been added.

A new feature of this edition is the inclusion of ultraviolet spectra. These, together with infra-red

spectra, now appear within the monographs for ease of reference.

The ultraviolet and infra-red data have been completely revised, as have the chromatographic data which now include high pressure liquid chromatography. Analytical information on many major metabolites is presented for the first time, and many monographs include the eight major mass spectral peaks for the substance and its major metabolites.

References to published methods for quantifying drugs in various biological fluids are given in the monographs, where available.

Many of the drug monographs contain a new section entitled 'Disposition in the Body'. This section details the absorption, distribution, and excretion of the drug, notes the major metabolites and therapeutic and toxic plasma concentrations, and gives values for pharmacokinetic parameters such as half-life, volume of distribution, clearance, and protein binding. In addition, abstracts from published clinical studies and case histories are included.

The presentation of literature references has been changed in this edition so that they now appear within the text rather than being collected together in an appendix.

Part 3: Indexes to Analytical Data

This part contains 64 indexes of analytical data, tabulated in numerical order, and includes all the data for chromatography, spectrophotometry, and mass spectrometry, together with indexes of molecular weight and melting point.

Part 4: Appendix of Reagents and Proprietary Test Materials

This part contains descriptions of reagents referred to in analytical procedures in Parts 1 and 2.

It has taken nearly 6 years to produce this second edition and during the whole of that time it has been very much a team effort with many collaborators. In particular, I give my warmest thanks to Eric Greenfield and Janet Batson who throughout the whole period have worked unstintingly to bring

the book to fruition. Although the work was detailed and exacting, they always managed to keep both their patience and their sense of humour. They have been ably assisted in the later stages by Christine Maule, Rosalind McLarney, Dinesh Mehta, and Prakash Gotecha at the Department of Pharmaceutical Sciences of The Pharmaceutical Society of Great Britain, and I thank them all for their stalwart work. Three consulting editors have also made invaluable contributions to the book and I am greatly indebted to John Jackson, Michael Moss, and Brian Widdop who not only provided advice, enthusiasm, and data, but also contributed chapters on their own specialist subjects.

Thanks are due in particular to the Central Research Establishment, Home Office Forensic Science Service, Aldermaston, for permission to use their analytical data and spectra, and to Mrs Myra Clarke FRCVS, for permission to use the name 'Clarke' in the new title of the book.

My former colleagues Howard Stead, Richard Gill, and Robert Ardrey at the Central Research Establishment, Home Office Forensic Science Service, have similarly given their time and enthusiasm and I owe a special debt of thanks to them for providing so much of the information included in the monographs as well as for their own chapters.

I also gratefully acknowledge the co-operation of the other authors of chapters in providing up-to-date accounts of their respective topics. There has also been a whole host of friends and colleagues who have helped one way or another to put this book together. Many who gave specific assistance are acknowledged on [p. xviii](#), but I take this opportunity to give my most grateful thanks to all those who have helped in the production of the book.

I must also record here the deaths of John Jackson and Donald Chapman during the preparation of this second edition. Their contribution will be used by others for years to come, and I deeply regret that John and Donald will not see the success of their work.

A.C. Moffat

July 1985

General Notices

The following explanatory notes are provided so that the reader can interpret and use the information given in the book. They should be studied before using the data given in the monographs in Part 2.

Health and Safety

This work is intended to be used by appropriately qualified and experienced scientists. Processes and tests described should be performed in suitable premises by personnel with adequate training and equipment. Care should be taken to ensure the safe handling of all chemical or biological materials, and particular attention should be given to the possible occurrence of allergy, infection, fire, explosion, or poisoning (including inhalation of toxic vapours). Cautionary notes have been included in a number of monograph entries, but the possibility of danger should always be kept in mind when handling biological samples, and medicinal or other chemical substances.

Classification

At the head of each monograph an indication is given of the classification of the compound according to its therapeutic or commercial use or its pharmacological action. The substance may, of course, have other uses or actions in addition to that stated.

Nomenclature

MONOGRAPH TITLES. The main titles of the monographs in Part 2 are usually British Approved Names, United States Adopted Names, or International Non-Proprietary Names, where these exist. For pesticides the nomenclature generally follows the British Approved Names, the British Standard Recommended Common Names, or the names issued by the International Organisation for Standardisation (ISO). In some approved names it is now general policy to use 'f' for 'ph' in sulpha, 't' for 'th', and 'i' for 'y'; for this reason entries in alphabetical lists and indexes should be sought in alternative spellings if the expected spellings are not found.

The main title of a monograph is generally that of the free acid or base as this is the form in which the compound will usually be isolated in an analysis; details of the commonly available salts are included in subsidiary paragraphs within the monograph.

The following abbreviated names for radicals and groups are used in the titles.

<i>Recommended name</i>	<i>Chemical name</i>
acetonide	isopropylidene ether of a dihydric alcohol
aceturate	<i>N</i> -acetylglucinate
besylate	benzenesulphonate
camsylate	camphor-10-sulphonate
caproate	hexanoate
closylate	4-chlorobenzenesulphonate
cypionate	3-cyclopentylpropionate
edetate	ethylenediamme- <i>NN'</i> <i>N''</i> -tetra-acetate
edisylate	ethane-1,2-disulphonate
eglumine	<i>N</i> -ethylglucamine
embonate	4,4'-methylenebis (3-hydroxy-2-naphthoate) (= pamoate)
enanthate	heptanoate
estolate	propionate
esylate	dodecyl sulphate
gluceptate	ethanesulphonate
hybenzate	glucoheptonate
isethionate	2-(4-hydroxybenzoyl)benzoate
lauryl sulphate	2-hydroxyethanesulphonate
meglumine	dodecyl sulphate
mesylate	<i>N</i> -methylglucamine
napadisylate	methanesulphonate
napsylate	naphthalene-1,5-disulphonate
pivalate	naphthalene-2-sulphonate
steaglate	trimethylacetate
tebutate	stearoyloxyacetate
theoclate	<i>tert</i> -butylacetate
tosylate	8-chlorotheophyllinate
	toluene-4-sulphonate

CHEMICAL NAMES. The nomenclature generally follows the definitive rules issued by IUPAC, 1979.

PROPRIETARY NAMES AND SYNONYMS. A selection of proprietary names have been included in the monographs in Part 2. In general, they apply to the United Kingdom, United States of America, Canada, and certain European countries. Comprehensive lists of proprietary names, world-wide, can be found in *Martindale, The Extra Pharmacopoeia*, 28th Edn, London, The Pharmaceutical Press, 1982. Only single-substance preparations have been included except in the case of certain major classes of drugs for which the names of some compound preparations have been added. Some proprietary names which are not in current use have been retained.

Names under the heading 'Synonyms' include alternative names, common titles, and abbreviations.

CAS REGISTRY NUMBERS. Chemical Abstracts

Service (CAS) registry numbers are provided, where available, in the monographs to assist readers to refer to other information systems.

Molecular Weights

Molecular weights have been calculated using the table of Atomic Weights as revised in 1977 by the Commission on Atomic Weights, XXIX IUPAC General Assembly, and based on the ^{12}C scale. Molecular weights have been corrected to four significant figures and are listed in ascending order in the index of Molecular Weights (p. 1073).

Physical Characteristics

DISSOCIATION CONSTANTS. Numerous methods can be used for the determination of dissociation constants, and there are often differences in the various values reported in the scientific literature. The pK_a values given in the monographs have been taken from published data and should be regarded only as approximate. The temperature at which the determination was made is given where known.

Information on the theory, measurement, and evaluation of dissociation constants is given in *The Pharmaceutical Codex*, 11th Edn, London, The Pharmaceutical Press, 1979.

MELTING POINTS. The melting points recorded in the individual monographs in Part 2 are listed in ascending order in the index of Melting Points (p. 1085).

PARTITION COEFFICIENTS. Values for $\log P$ are given in a number of monographs. Where the pH of the aqueous phase is stated, the values given are apparent coefficients at that pH (not ion-corrected). Where no pH is stated for the aqueous phase, it can be assumed that $\log P$ is for the neutral form of the substance even though it is potentially ionisable.

The values given are approximate only but they serve to indicate the characteristics of the substance when it is submitted to an extraction process.

For a comprehensive collection of partition coefficients for drugs see C. Hansch and A. J. Leo, *Substituent Constants for Correlation Analysis in Chemistry and Biology*, Chichester, John Wiley, 1979. Information on the theory, determination, and use of partition coefficients is given in *The Pharmaceutical Codex*, 11th Edn, London, The Pharmaceutical Press, 1979.

SOLUBILITY. The solubilities given in the monographs in Part 2, unless otherwise stated, apply at ordinary room temperature. They have been obtained from various sources and should not be regarded as precise because of variations depending on the method and conditions of determination. In general, approximate

values are given when a substance is soluble in less than 1000 parts of solvent. Where no figure is given, the usual solubility terms have been adopted:

very soluble	1 in less than 1
freely soluble	1 in 1 to 1 in 10
soluble	1 in 10 to 1 in 30
sparingly soluble	1 in 30 to 1 in 100
slightly soluble	1 in 100 to 1 in 1000
very slightly soluble	1 in 1000 to 1 in 10000
practically insoluble	1 in more than 10000

In the solubility statements, the word 'water' refers to purified water, the word 'ether' refers to diethyl ether, and the word 'ethanol', without qualification, refers to ethanol (95%).

TEMPERATURE. Temperatures are expressed throughout the text in degrees Celsius (Centigrade).

Analytical Data

All analytical data in the monographs in Part 2 apply to the form of the substance described in the main title of the monograph, unless otherwise specified.

In all lists or indexes of chromatographic data, a dash indicates that the value is not known, not that the substance does not elute.

EXTRACTION. It has not been possible to give direct information on the best method for extracting individual substances from various biological samples. However, useful information can be gained from the data on solubility, dissociation constant, and partition coefficient. The best solvent can be chosen by reference to the solubility, the pH for extraction is indicated by the pK_a value, and the partition coefficient gives a quantitative measure of the phase volume ratios needed for a successful extraction.

COLOUR TESTS. Where colour tests are given in the monographs in Part 2, the names of the tests are printed with initial capitals. These names refer to the tests described under Colour Tests (pp. 128 to 147) where complete tables of colours are provided. Reference should be made to this chapter for an explanation of the system used for describing the colours.

Colour tests applicable to biological fluids are described under Hospital Toxicology and Drug Abuse Screening (pp. 3 to 34).

THIN-LAYER CHROMATOGRAPHY. The thin-layer chromatographic systems referred to in the monographs in Part 2 are described on pp. 167 to 177, together with lists of data for drugs in important chemical and pharmacological classifications. General screening systems (Systems TA to TF), which

include over 700 drugs, are provided. System TA is the same as System T1 which appeared in the first edition but the data have been completely revised and extended. In order to clarify the presentation of values, the data are expressed in terms of $R_f \times 100$. Complete lists of data, in ascending order, are given in the indexes of Thin-layer Chromatographic Data (p. 1094).

GAS CHROMATOGRAPHY. The gas chromatographic systems referred to in the monographs in Part 2 are described on pp. 192 to 200, together with lists of retention data for drugs in important chemical and pharmacological classifications. A general screening system (System GA), which includes over 700 drugs, is provided. For most of the systems, the data are given in terms of Retention Index (see p. 190). Retention times or relative retention times are used in a few systems. Complete lists of retention data, in ascending order, are given in the indexes of Gas Chromatographic Data (p. 1112).

HIGH PRESSURE LIQUID CHROMATOGRAPHY. The high pressure liquid chromatographic systems referred to in the monographs in Part 2 are described on pp. 213 to 220, together with lists of retention data for drugs in important chemical and pharmacological classifications. A general screening system (System HA), which includes over 400 drugs, is provided. For the majority of the systems, the data are given in terms of column capacity ratio, k' (see p. 204). Complete lists of retention data, in ascending order, are given in the indexes of High Pressure Liquid Chromatographic Data (p. 1121).

ULTRAVIOLET ABSORPTION. The wavelengths of principal and subsidiary peaks, in the range 230 to 360 nm, are recorded in each monograph for acid, alkaline, and neutral solution, where available. Values in neutral solution are given for compounds for which values in acid or alkaline solution are not available or when the values in neutral solution differ significantly from those in acid or alkaline solution. In many monographs, the ultraviolet spectrum is reproduced. In these spectra the following notation is used

_____	acid solution
.....	alkaline solution
-----	neutral solution

Where more than one curve is shown, they do not necessarily relate to the same concentration and, consequently, points where the curves cross cannot

be taken as true isosbestic points. The wavelengths peaks in a few of the spectra may differ very slightly from those stated in the text. Where there is doubt, the values given in the text should be used. In monographs where the spectrum is reproduced, A_1^1 value for the major peak only is given; if no spectrum is reproduced, the A_1^1 value for each peak is stated, if available. The A_1^1 values apply to the form of the substance described in the main title of the monograph, unless otherwise stated.

The A_1^1 values are divided into three categories in order to provide an indication of reliability:

The letter 'a' after a figure indicates that the value is a mean value based on several reported figures all of which lie within a range of $\pm 10\%$ of the mean.

The letter 'b' after a figure indicates that the value is a single reported value of unknown reliability. The letter 'c' after a figure indicates that the value is a mean value based on several reported figures some of which lie outside $\pm 10\%$ of the mean.

The phrase 'no significant absorption' indicates that no peaks are found at the concentrations normally used.

The A_1^1 values quoted in the monographs may be useful in identification, and may help in determining the strength of a solution which is required to obtain a curve within the instrumental range of absorption. They may also be useful to give an approximate indication of the amount of drug present in a solution. However, because of instrumental differences and the possible effect of solvent and pH, A_1^1 values are subject to considerable variation and the values quoted should not be used when an accurate assay is required. In this case, a reference specimen should be examined at the same time as the sample.

The wavelengths of main peaks are listed for acid, alkaline, and neutral solution in the index of Ultraviolet Absorption Maxima (p. 1128).

INFRA-RED ABSORPTION. The wavenumbers of the six major peaks in the range 2000 to 650 cm^{-1} (5 to 15 μm), in descending order of amplitude, are recorded in the monographs in Part 2. In many cases the infra-red spectrum is also reproduced. When selecting the six principal peaks, those which are in the region where Nujol absorbs (1490 to 1320 cm^{-1} , 6.7 to 7.6 μm) have been omitted. Corrections for calibration errors have been applied where these are known.

The six principal peaks, in ascending order of the main peak, are listed in the index of Infra-red Peaks (p. 1141).

MASS SPECTRUM. The m/z values of the eight most abundant ions, in descending order of intensity, are included in many monographs in Part 2. Where dashes occur in the listing this indicates that less than eight ions have been observed.

The eight principal peaks, in ascending order of the main peak, are listed in the index of Mass Spectral Data of Drugs (p. 1152). A separate index for pesticides is on p. 1161. The full mass spectra for the majority of the listed compounds are displayed in *Pharmaceutical Mass Spectra*, London, The Pharmaceutical Press, 1985.

QUANTIFICATION. The methods referred to in the references quoted under the heading 'Quantification' in the monographs in Part 2 are not intended to be recommended methods. These references are intended to be used as a guide to the literature on the particular subject.

REAGENTS. Reagents required for specific tests or methods are generally described fully in the appropriate place in the text. However, certain common reagents which are used throughout the book are italicised in the text and are described in Part 4: Appendix of Reagents and Proprietary Test Materials (p. 1169). Reagent solutions are made in purified water unless otherwise specified. When ethanol, without qualification, is stated to be used, this refers to ethanol (95%).

Unless otherwise stated, solutions of solids in liquids are expressed as percentage w/v, and solutions of liquids in liquids as percentage v/v. When acids of various strengths are specified, e.g. 50% sulphuric acid, this implies the appropriate dilution by volume of the strong acid in water.

Disposition in the Body

Many of the monographs in Part 2 contain a section with the heading 'Disposition in the Body'. The information in these statements has been obtained from a detailed survey of published papers and other reference sources. Certain monographs have a single reference at the end of the statement and this indicates that all the disposition information has been obtained from that source. Wherever possible, information is included on absorption, distribution, metabolism, excretion, therapeutic concentration, toxicity, and pharmacokinetic parameters.

Entry to the literature is provided by the inclusion of abstracts of published papers on clinical studies or case histories. These abstracts include details of drug concentrations in plasma or other body fluids or tissues; in these data a dash means that

the particular value was not determined, and ND or 0 means that the substance was not detected. Concentrations in body fluids or tissues are expressed in $\mu\text{g/ml}$ or $\mu\text{g/g}$.

In some monographs the information is incomplete, the amount of detail being dependent upon that available in the literature searched. It should not be assumed that the statements presented reflect the only significant factors in the disposition of the drug concerned.

THERAPEUTIC CONCENTRATION. This is the concentration range usually observed after therapeutic doses, as reported in clinical studies and other research projects. It should not be interpreted as the concentration range required for optimum therapeutic effect.

TOXICITY. This statement may include drug concentrations in blood or other body fluids or tissues, which have been reported to be associated with toxic or lethal effects. Because of intersubject variations or other variable factors, the reported toxic or lethal concentrations may occasionally lie close to or within the therapeutic range.

In some monographs, the toxic or lethal blood concentrations are stated in the form 60 to 89 to 150 $\mu\text{g/ml}$. These figures have been obtained from a survey of a number of reported cases and represent the maximum concentrations found in 10%, 50%, and 90% of the subjects, respectively.

Maximum permitted concentrations in air (8-hour exposure limit) are those recommended by the Health and Safety Executive in *Occupational Exposure Limits 1985*, Guidance Note EH 40/85, London HMSO.

VOLUME OF DISTRIBUTION. This relates to plasma; concentrations after intravenous administration unless otherwise stated. Values are based on a body weight of 70 kg.

CLEARANCE. This usually refers to the total plasma; clearance (or total whole blood clearance) after intravenous administration. In some instances the total clearance after an oral dose has been included if the drug is known to be well absorbed and is no subject to significant first-pass metabolism.

Numerous factors and intersubject variations may affect the absorption, distribution, metabolism, and excretion of drugs. These include age, sex, and disease states such as renal impairment. In addition results of analyses may be subject to unavoidable analytical inaccuracies. Consequently, there may be considerable variations in the observed drug concentrations and in values for pharmacokinetic

parameters in individual cases. Hence, the values given in the monographs should be used only as a guide and should not be taken as absolute values.

Dose

The dose recorded under this heading in the monographs in Part 2 indicates the usual daily dose (oral unless otherwise stated) that may be administered for therapeutic purposes. It is intended solely as a guide in deciding whether the amount taken by an individual falls within the normal dosage range and should not be taken as a recommendation for treatment.

More detailed information on doses in different conditions and age groups may be found in *Martindale, The Extra Pharmacopoeia*, 28th Edn, London, The Pharmaceutical Press, 1982, or in the manufacturers' data sheets for the products.

This second edition of Clarke could not have been completed without the comments on the first edition and the contribution of analytical data from many scientists involved in the analysis of drugs. In order to assist in the preparation of a third edition, the reader is invited to send any constructive comments and relevant new data concerning the analysis of drugs in biological materials to the Editor, Clarke's Isolation and Identification of Drugs, Department of Pharmaceutical Sciences, The Pharmaceutical Society of Great Britain, 1 Lambeth High Street, London SE1 7JN, England. In this way, future editions of the book will be improved to the benefit of all those who use it.

Deletions

The following substances which were included in Volumes 1 and 2* of the 1st Edition are not included in this edition.

Acetyldihydrocodeine	Azamethonium Bromide
Adrenalone	Benzalkonium Bromide
Allantoin	Benzamine
Allylprodine	Benzathine Penicillin
Alphameprodine	Benzethidine
Alphamethadol	Betameprodine
Aminometradine	Betaprodine
Aminopentamide	*Brocresine
Amisometradine	Butallylonal
Amolanone	Butethamine
Amopyroquine	Butoxamine
*Amotriphene	Cetoxime
Amprotropine	Chlorisondamine Chloride
Amydracaine	Citronella Oil
Amylocaine	Clamoxyquin
Apoatropine	Clonitazene
Azacosterol	*Cloponone

Codeine <i>N</i> -Oxide	*Naftazone
Cyclamic Acid	Narcobarbital
Cyprenorphine	Nicocodine
Demecolcine	Nicomorphine
Demeton-0	*Niiuroxime
Desomorphine	Noracymethadol
Diampromide	Norbutrine
Dibutoline Sulphate	*Nordefrin
*Diethylaminoethyl	*Norgestrel
Diphenylpropionate	Norlevorphanol
Dimenoxadole	*Octacaine
*Dimethocaine	Octaverine
Dimethylthiambutene	Orthocaine
*Dimophebumine	Pamaquin
Dioxaphetyl Butyrate	*Panidazole
Dioxa thion	*Paromomycin
*Dioxyamidopyrine	Pentaquin
*Diphenazoline	*Pethidine Intermediate A
Dithiazanine Iodide	Phenadoxone
Embramine	Phenamidine
Erythrityl Tetranitrate	Phenampromide
*Ethylisobutrazine	*Phenatine
Ethylmetylthiambutene	Phenisonone
*Ethylpiperidyl Benzilate	Phenomorphane
Etonitazene	Phenoxypropazine
Etoxadine	Phenylpropylmethylamine
Etymide	*Phthivazid
Fenimide	*Picloxydine
*Fenmetramide	Pipamazine
Furethidine	Piperoxan
Hydromorphinol	Pipethanate
Hydroxypethidine	Plasmocide
*Imidocarb	*Proadifen
*Iminodimethylphenylthiazolidine	Probarbital
*Ipydol	Proheptazine
*Ipydone	Propredine
Isobutyl Aminobenzoate	Pulegium Oil
*Isometamidium	*Pyrrocaine
Isomethadone	Quinapyramine Chloride
Laudexium Methylsulphate	Racemethorphan
Leucinocaine	Racemoramide
Levomethorphan	*Resorantel
Levomoramide	*Rifamide
Levophenaclymorphan	*Rolicypram
Lucanthone	Stilbamidine
Metabutethamine	Sulphasomizole
Metabutoxycaine	Sulphonol
Metazocine	*Taurolin
*Methadone Intermediate	Teclothiazide
Methaphenilene	*Terodiline
Methoxypropazine	*Tetracosactrin
Methylaminoheptane	*Tetraethylammonium Bromide
Methylde-sorphine	*Thozalinone
Methyldihydromorphine	Thurfyl Nicotinate
Methylhexaneamine	*Tiletamine
Methyridine	Tolonium Chloride
Metofoline	Tolycaine
Metopon	Triclobisonium Chloride
*Moramide Intermediate	Tropacocaine
Morpheridine	Tropine
Morphine <i>N</i> -Oxide	Tymazoline
Mustine	Viomycin
Myrophine	Xenysalate
Naepaine

Abbreviations

A number of units, terms, and symbols are not included in this list as they are defined in the place in the text where they are used. Very common abbreviations (gram, centimetre, etc.) have been omitted. The titles of journals are abbreviated according to the general style of *World List of Scientific Periodicals* (London, Butterworths, 1963-80).

A_1^1 —specific absorbance (abbreviation of $A_{1\text{cm}}^{1\%}$)
 AFID—alkali flame ionisation detector
 agg.—aggregate (in botanical names), including 2 or more species which resemble each other closely
 AUC—area under the curve
 B.P.—British Pharmacopoeia
 b.p.—boiling point
 CAS—Chemical Abstracts Service
 CI—Colour Index (*Colour Index*, 3rd Edn, 1971 and supplements)
 Cl—clearance
 ECD—electron capture detector
 Ed.—editor(s) *or* edited by
 Edn—edition
et al.—*et alii*, ‘and others’: for three or more co-authors or co-workers
 eV—electron volt(s)
 fg—femtogram(s)
 FID—flame ionisation detector
 f.p.—freezing point
 FPD—flame photometric detector
 ft—foot (feet)
 GC—gas chromatography
 GC-MS—gas chromatography-mass spectrometry
 GCDP—gas chromatographic decomposition product
 GSC—gas-solid chromatography
 h—hour(s)
 HPLC—high pressure liquid chromatography
 HPLC-MS—high pressure liquid chromatography-mass spectrometry
ibid.—*ibidem*, ‘in the same place’ (journal or book)
idem—‘the same’: used for the same authors and titles
 in—inch(es)
 IR—infra-red
 k’—column capacity ratio

λ —wavelength (nm)
 log—logarithm to the base 10
 ln—logarithm to the base e (natural logarithm)
 μg —microgram(s)
 μm —micrometre(s)
 M—molar, i.e. the strength of a solution in moles per litre
 mEq—milliequivalent(s)
 MID—multiple ion detector
 min—minute
 mol—mole
 m.p.—melting point
 MS—mass spectrometry
 m/z —mass to charge ratio
 V—frequency (Hz)
 \bar{V} —wavenumber (cm^{-1})
 ng—nanogram(s)
 nm—nanometre(s)
 NMR—nuclear magnetic resonance
 P—apparent partition coefficient
 pg—picogram(s)
 PID—photoionisation detector
 pKa—the negative logarithm of the dissociation constant
 PMR—proton magnetic resonance
 ppm—part(s) per million
 PTFE—polytetrafluoroethylene
 RI—retention index
 RIA—radioimmunoassay
 RRT—relative retention time
 RT—retention time
 s—*second(s)*
 s—standard deviation
 sp.gr.—specific gravity
 sp.—species (plural spp.)
 $t_{1/2}$ —half-life
 TCD—thermal conductivity detector
 TIC—total ion current
 TLC—thin-layer chromatography
 UV—ultraviolet
 V—volt(s)
 V_d —volume of distribution
 var.—variety
 Vet.—veterinary
 vol.—volume(s)
 v/v—volume in volume
 w/v—weight in volume
 w/w—weight in weight

Part 1: Analytical techniques

Hospital Toxicology and Drug Abuse Screening

B. Widdop

When tablets or capsules are found in the immediate vicinity of, or in the possession of, an unconscious patient, it is reasonable to assume that a drug overdose has been taken. If the patient responds to supportive treatment and no active measures are contemplated, toxicological analyses are of historical interest only. Conversely, when circumstantial evidence is lacking, a diagnosis of poisoning may be difficult to sustain simply on the basis of clinical examination, since coma induced by drugs is not readily differentiated from that caused by disease processes. The role of the laboratory is important in several types of poisoning cases.

In the diagnosis of brain death, the presence of depressant drugs with prolonged duration of action should be excluded. Episodes of cardiac arrest, hypoxia, or severe circulatory insufficiency occur frequently in severely-overdosed patients, and can lead to cerebral anoxia and brain death. Measurement of the plasma concentration of the drug(s) to establish the presence or absence of toxic concentrations is invaluable in this context.

Poisoning in children is mainly accidental but deliberate poisoning by parents or guardians may go unrecognised. Suspicions are aroused when a child shows bizarre symptoms and signs for which there is no obvious pathological explanation. The detection of drugs in samples from these cases does not prove that the child has been wilfully poisoned, but sufficient concern may be generated to ensure future supervision by the social services.

In the diagnosis and monitoring of drug abuse, clinicians rely heavily on laboratory tests. The analyses guard against the issuing of drugs to patients who may not be dependent on them, and help to assess the progress (or otherwise) in treating genuine addicts.

Signs of endogenous mental illness are often hard to differentiate from those induced by psychotomymetic agents (e.g. amphetamine, cannabis, lysergide), and laboratory analyses can be an invaluable diagnostic aid.

In certain poisoning cases a specific antidote may be available, e.g. for carbon monoxide,

cholinesterase inhibitors, cyanide, heavy metals, iron, methanol, ethylene glycol, opiates, paracetamol, and some halogenated hydrocarbons. If the circumstantial and clinical evidence is clear, the clinician may administer the antidote without waiting for confirmatory laboratory tests. However, subsequent analyses may be a useful guide to the need to continue therapy. For example, parenteral therapy of iron poisoning with desferrioxamine is indicated if the clinical state of the patient deteriorates and the serum-iron concentration is extremely high;

information about cholinesterase activity in serum or erythrocytes is useful when massive doses of atropine are being infused into patients suffering from organophosphate poisoning; intravenous infusions of acetylcysteine can be discontinued if the plasma-paracetamol concentration demonstrates that a patient is unlikely to sustain liver damage. The abuse of solvents ('glue-sniffing') is increasing, and patients who reach hospital have a variety of neurological signs. The detection of the responsible agents in blood proves the diagnosis.

Covert ingestion of laxative drugs is a lesser known facet of drug misuse. These patients, convinced that daily evacuation of the bowel is essential for survival, take laxatives in quantities which lead to persistent gastro-intestinal and systemic disorders. Other patients self-administer diuretic agents, usually to lose weight, and again systemic disturbances are induced. Analytical tests to detect all these drugs can avoid months of fruitless clinical, biochemical, and haematological investigations.

Collection of samples

Urine

A urine specimen should be obtained from the patient on admission to hospital, preferably before any drugs (e.g. diuretics, tranquillisers) which may interfere with the tests have been administered.

Unconscious patients are usually catheterised and, in this case, the sample may be contaminated with the catheter lubricant which frequently contains lignocaine as a local anaesthetic. Urine is ideal for qualitative screening as it is available in large volumes, and usually contains higher concentrations of drugs or poisons than blood. The presence of drug metabolites can be used to assist identification if chromatographic techniques which can separate them are used. A 50-ml sample is sufficient for a comprehensive series of tests, and no preservative should be added.

Stomach Contents

This sample includes vomit, gastric aspirate, or stomach washings. It is important to obtain the first sample of washings rather than a later sample which will be considerably diluted. This is the most useful sample on which to carry out qualitative analyses; if it is obtained soon after the overdose was taken it may be possible to recognise the presence of undegraded tablets or capsules. An immediate clue may be obtained by detecting the characteristic odour of certain compounds. However, the main virtue of this sample is that the drugs are present in high concentrations. The sample is also devoid of metabolites which complicate some assays. At least 50 ml of sample is required to carry out a wide range of tests, and no preservative should be added.

Blood

Samples which should be taken on admission of the patient are 10 ml of heparinised blood, 2 ml of fluoridated blood, and 10 ml of blood without preservative or anticoagulant. The use of disinfectant swabs containing alcohols, and of heparin containing phenolic preservatives, should be avoided. The sample should be dispensed with care; for example, the vigorous discharge of blood through a syringe needle can cause sufficient haemolysis to invalidate a serum-iron assay. Any drugs administered to the patient for treatment of the poisoning must be reported to the laboratory.

Rapid Detection of Drugs Commonly Taken in Overdosage

Two analytical schemes are presented, both of which have been devised to give a simple method for indicating the identity of the drug or drug-type which may be present in a sample of blood, urine, or stomach contents.

Scheme 1 is designed to produce the maximum

amount of useful information in the minimum time. It includes preliminary direct tests followed by solvent extraction and thin-layer chromatography, and a test for benzodiazepines in urine. If evidence exists which suggests a specific drug, the appropriate test should be carried out first. However, it must be remembered that patients frequently ingest more than one drug, and it is unwise to discontinue the analysis at the first sign of a positive result. When a drug has been detected, it can be identified and quantified using tests described later in this chapter.

Scheme 2 can be used when more time is available for the analyses. It involves a more elaborate extraction procedure, with separation into strong acid, weak acid, neutral, and basic fractions.

SCHEME 1

Direct Tests on Urine, Stomach Contents, and Blood

DIRECT TEST ON URINE

1. Glucose, ketones, and pH—'Labstix' test.

Dip a 'Labstix' strip briefly into the urine and read after 10 to 15 seconds. For glucose, the result should be correlated with blood-glucose determination. A positive result for ketones may indicate intoxication by acetone or isopropyl alcohol. This test may also be positive in starvation or in diabetic ketosis.

2. Salicylates—Trinder's test.

To 1 ml of urine add 5 drops of *Trinder's reagent*.

A violet colour indicates the presence of salicylate or salicyl-amide. A positive result is obtained after therapeutic doses of aspirin or aminosalicilyc acid.

3. Volatile reducing substances (including alcohols and aldehydes)—dichromat test.

Place 1 ml of urine in a test-tube; apply 1 drop of 2.5% potassium dichromate in 50% sulphuric acid to a strip of glass-fibre filter paper, insert the paper in the neck of the test-tube, lightly cork the tube, and place in a boiling water-bath for 2 minutes. A colour change to green indicates a positive result. Ethanol, the most commonly found member of this group, gives a positive reaction if present above 400 mg/ml and the blood-ethanol concentration should then be measured (p. 19).

4. Phenothiazines—FPN reagent.

To 1 ml of urine add 1 ml of *FPN reagent*. A variety of colours ranging through pink, red, orange, violet, and blue indicates the presence of a phenothiazine derivative. The colours are transient and should be observed immediately. Positive results can be obtained after therapeutic doses.

5. *Imipramine, desipramine, and trimipramine—Forrest reagent.* To 0.5 ml of urine add 1 ml of *Forrest reagent*. A green-yellow colour darkening through dark green to blue, depending on the amount of drug present, immediately appears. Phenothiazines may also give a positive result, but the test is more sensitive than FPN reagent to imipramine.

6. *Trichloro-compounds—Fujiwara test.* To 1 ml of urine add 1 ml of *sodium hydroxide solution* and 1 ml of pyridine, and heat in a boiling water-bath for 2 minutes. The development of a red colour in the pyridine layer indicates ingestion of a trichloro-compound. A blank urine sample and an authentic solution of trichloroacetic acid should be tested at the same time, both blank and control solutions being treated in similar fashion to the sample, because contamination of the atmosphere with laboratory reagents may give positive results.

Metabolites of carbon tetrachloride may also give a positive result with this test, but carbon tetrachloride is only partially metabolised to trichloromethyl compounds and the test may fail to detect this agent. If carbon tetrachloride poisoning is suspected, evidence of hepato-toxicity should be sought by carrying out appropriate serum-enzyme assays.

7. *Paracetamol—Cresol-ammonia test.* To 0.5 ml of urine add 0.5 ml of *hydrochloric acid* and heat for 10 minutes at 100°; to 2 drops of the mixture add 10 ml of water, 1 ml of 1 % *o*-cresol in water, and 4 ml of 2M ammonium hydroxide. A blue colour appears if paracetamol is present. The test is very sensitive and can detect therapeutic concentrations. The presence of the parent drug and its conjugated metabolites can be detected for several days after overdose. If a positive result is obtained, a plasma-paracetamol determination should be carried out immediately (p. 23).

8. *Ethchlorvynol—diphenylamine test.* Sprinkle a few mg of diphenylamine sulphate on to the surface of 2 ml of urine in a test-tube, incline the tube, and carefully trickle in 1 ml of *sulphuric acid*. A red colour forms on the surface of the crystals if ethchlorvynol is present.

The test is specific, and is sufficiently sensitive to detect therapeutic concentrations.

9. *Paraquat and diquat—dithionite test.* To 1 ml of

urine add 1 ml of a freshly-prepared 0.1% solution of sodium dithionite in 1 sodium hydroxide. A blue colour indicates the presence of paraquat. A green colour is given by diquat, but paraquat may also be present.

A strong blue colour obtained with a urine sample taken more than 4 hours after ingestion suggests a poor prognosis. Confirmation of the severity of the poisoning is obtained by measuring the plasma-paraquat concentration (p. 25).

DIRECT TESTS ON STOMACH CONTENTS

1. *Odour, colour, and pH.* Characteristic smells may indicate the presence of substances such as camphor, cresol, cyanide, ethanol and other organic solvents, ethchlorvynol, methyl salicylate, paraldehyde, and phenelzine. A high pH may indicate ingestion of alkali. Undegraded tablets or capsules should be retrieved and examined separately. A green or blue colour suggests the presence of iron salts.

2. *Salicylates—Trinder's test.* To 2ml of the sample add 2ml of 0.1M hydrochloric acid, boil for 10 minutes, filter if necessary, neutralise the filtrate with 0.1M sodium hydroxide, and add 3 drops of *Trinder's reagent*. A violet colour indicates the presence of salicylate. Aspirin itself will not react with the reagent as preliminary hydrolysis is required.

3. *Oxidising agents—diphenylamine test.* Filter a portion of the sample and add 2 drops of the filtrate to 1 ml of a 1% solution of diphenylamine in *sulphuric acid*. A deep blue colour, appearing immediately, indicates the presence of an oxidising agent. The test will detect hypochlorite (from domestic bleach), bromates, chlorates, iodates, nitrates, and nitrites. Tests to distinguish between certain anions will be found under Metals and Anions (p. 64).

A light blue colour, caused by organic matter, should be ignored. Note that nitrate and nitrite from meat products will give a positive reaction.

4. *Ferrous and ferric iron—ferricyanide and ferro-cyanide tests.* To 2 drops of sample add 3 drops of 2M hydrochloric acid and 1 drop of 1% potassium ferricyanide solution. A deep blue precipitate indicates ferrous iron. Repeat the test but adding 1 drop of 1% potassium ferrocyanide solution. A deep

blue precipitate indicates ferric iron.

5. Phenothiazines—FPN reagent.

Carry out the test as described for urine (above) using a suitable volume of the filtered sample.

6. Imipramine, desipramine, and trimipramine—Forrest reagent. Carry out the test as described for urine (above) using a suitable volume of the filtered sample.

7. Trichloro-compounds—Fujiwara test. Carry out the test as described for urine (above) using a suitable volume of the filtered sample.

8. Ethchlorvynol—diphenylamine test. Carry out the test as described for urine (above) using a suitable volume of the filtered sample.

9. Paraquat and diquat—dithionite test. Carry out the test as described for urine (above) using a suitable volume of the filtered sample.

10. Organophosphorus compounds—inhibition of cholinesterase. To each of two tubes add 3 ml of dithiobisnitrobenzoic acid solution, 0.1 ml of 5% acetylthiocholine iodide solution, and 20 ml of normal serum; to the first tube add 0.2 ml of water and to the second tube add 0.2 ml of the filtered sample and allow to stand for 2 minutes. Any significant difference in colour between the tubes is suggestive of the presence of an organophosphorus compound or other cholinesterase inhibitor.

The method given for the quantification of cholinesterase activity in serum (p. 23) may also be applied to stomach contents.

DIRECT TESTS ON BLOOD

1. Glucose. Measure the blood glucose by a standard method or, approximately, by the 'Dextrostix' or similar method. Hypoglycaemia is a feature of overdosage with insulin, hypo-glycaemic agents, and ethanol. It can also occur in the early stages of liver damage following severe poisoning with paracetamol.

2. Urea. Measure the blood urea by a standard method or, approximately, by the 'Urastrat' method (see Reagent Appendix), to exclude uraemia.

3. Carbon monoxide—carboxy haemoglobin test. Dilute a sample of the blood 1 in 20 with 0.01M ammonia and compare the colour with sample of normal blood treated similarly. A pinkish tint suggests the presence of carboxyhaemoglobin.

4. Salicylates—Trinder's test. To 0.5 ml of plasma add 4.5 ml of *Trinder's reagent*, shake well, and centrifuge. A violet colour in the supernatant liquid indicates the presence of salicylate or salicylamide.

A quantitative method for salicylate in plasma is given on p. 26.

5. Volatile reducing substances (including alcohols and aldehydes)—dichromate test. Carry out the method described for urine, above.

6. Organophosphorus compounds—inhibition of cholinesterase. To each of two tubes add 3 ml of dithiobisnitrobenzoic acid solution and 0.1 ml of 5% acetylthiocholine iodide solution; to the first tube add 20 μ l of normal serum and to the second tube add 20 μ l of the sample serum and allow to stand for 2 minutes. Any significant difference in colour between the tubes is suggestive of the presence of an organophosphorus compound or other cholinesterase inhibitor. A method for the quantification of cholinesterase activity in serum is given on p. 23.

Extraction of Urine and Stomach Contents

This procedure gives an extract which can be analysed by thin-layer chromatography. If both types of sample are available, they should both be examined. If necessary, particulate material in stomach contents should be removed by filtration or centrifugation, and the clarified filtrate or supernatant liquid extracted. Direct extracts of stomach contents, when evaporated to small bulk, are difficult to apply to thin-layer chromatographic plates because of the presence of fats and other dietary material. For this sample, therefore, a back-extraction step is included in the procedure.

Half-fill each of two 20-ml screw-capped glass bottles (McCartney bottles) with sample, and make one acidic by the addition of 1 to 2 ml of M sulphuric acid, and the other alkaline by the addition of 1 to 2 ml of M sodium hydroxide (check the pH with an indicator paper). Label the bottles A and B (acids and bases) respectively, fill them with chloroform, screw on the plastic caps, shake gently for about 5 minutes, and centrifuge for 5 to 10 minutes. Remove the top aqueous layer using a Pasteur pipette connected to a water-operated vacuum pump.

For samples of stomach contents, carry out the following back-extraction procedure. Add 3 ml of 0.5M sodium hydroxide to the acid chloroform extract (A), and 3 ml of 0.25M sulphuric acid to the alkaline chloroform extract (B). Shake the bottles again, centrifuge, and discard the organic solvent layers. Make bottle A acid by the addition of 0.5 ml of 3M sulphuric acid, and make bottle B alkaline by the addition of 0.5 ml of 6M sodium hydroxide.

Add 10 ml of chloroform to each bottle, shake, centrifuge, and remove the aqueous layers as above. Remove residual moisture from the two extracts from either urine or stomach contents by filtering through phase-separating paper, and collect the filtrates in 10-ml conical test-tubes. Add a little tartaric acid to the basic extract to prevent the loss of volatile bases, and evaporate to dryness under a stream of air or nitrogen. Dissolve each residue in 0.1 ml of chloroform.

Thin-layer Chromatography of Extracts

ACIDIC AND NEUTRAL EXTRACT

Reference Solutions. Prepare solutions in chloroform of authentic samples of drugs as indicated in Table 1, each drug being at a concentration of 1 mg/ml.

Method. Divide a TLC plate (silica gel G, 250 μm) into 8 equal columns by scoring lines with a spatula, and draw a horizontal line 10 cm from the origin. Apply 10- μl aliquots of the reference solutions and 25- μl aliquots of the sample extract to the columns on the plate in the sequence shown in Table 1. Evaporation of the spots can be hastened by the use of a cold air blower.

Table 1. Sequence of application of acidic extract to TLC plate

Column number	Solution
1	amylorbarbitone and phenobarbitone
2	sample extract
3	phenobarbitone and phenytoin
4	sample extract
5	glutethimide
6	sample extract
7	meprobamate
8	sample extract

Develop the plate in a tank containing 100 ml of a 4:1 mixture of chloroform: acetone (System TD, p. 168). Alternatively, System TE (p. 168), or System TF (p. 168) may be used. After development, remove the plate from the tank and dry under a stream of cold air.

NOTE. Chloroform and acetone can form an explosive mixture in the presence of alkali and should be disposed of immediately after use.

Location Reagents. Examine the plate under ultraviolet light.

Cover columns 3 to 8 with a glass plate and spray columns 1 and 2 with *mercuric chloride-diphenylcarbazone reagent*. White spots on a violet background indicate the presence of barbiturates or related compounds (e.g. glutethimide). Cover columns 1 and 2 and 5 to 8 with glass plates,

and spray columns 3 and 4 with *mercurous nitrate spray*. Black spots are given by barbiturates and related compounds (e.g. glutethimide). Cover columns 1 to 4 and 7 and 8 with glass plates, and spray columns 5 and 6 with *Dragendorff spray*. An orange spot is given by methaqualone and by glutethimide (weak reaction). Cover columns 1 to 6, and spray columns 7 and 8 with *furfuraldehyde reagent*. A violet spot is given by meprobamate.

The chromatographic system distinguishes between certain types of barbiturates, and for most clinical situations this is sufficient. If doubt exists, or if it is crucial to know which barbiturate is present, the sample should be examined by gas chromatography. Certain antibiotics give white spots with *mercurous nitrate spray*, but do not react with *mercuric chloride-diphenylcarbazone reagent*.

Table 2. TLC data for some acidic and neutral drugs

Compound	Rf Values Systems			Mercuric chloride- diphenyl-carbazone reagent	Mercurous nitrate spray
	TD	TE	TF		
Primidone	8	39	26	+	+
Meprobamate*	9	60	34	—	—

Phenylbutazone	78	66	68		+

*Violet with *furfuraldehyde reagent*

†Weak reaction with *Dragendorff spray*

‡Positive reaction with *Dragendorff spray*

An alternative sequence of spray reagents, and alternative reference compounds, are given for Systems TD, TE, and TF on p. 168, and a comprehensive list of Rf values in these systems will be found in the indexes to Thin-layer Chromatographic Data in Part 3.

BASIC EXTRACT

Reference Solutions. Prepare solutions in chloroform of authentic samples of drugs as indicated in Table 3, each drug being at a concentration of 1 mg/ml.

Method. Divide a TLC plate (silica gel G, 250 μm)

into 8 equal columns by scoring lines with a spatula, and draw a horizontal line 10 cm from the origin. Apply 10- µl aliquots of the authentic solutions and 25-µl aliquots of the sample extract to the columns on the plate in the sequence shown in Table 3. Evaporation of the spots can be hastened by the use of a cold air blower.

Table 3. Sequence of application of basic extract to TLC plate

Column number	Solution
1	codeine
2	sample extract
3	amitriptyline and nortriptyline
4	sample extract
5	chlorpromazine
6	sample extract
7	*suspected drug
8	sample extract

*Column 7 is reserved for an authentic solution of any basic drug which may be suspected on clinical or circumstantial evidence.

Develop the plate in a tank containing a 100:1.5 mixture of methanol: *strong ammonia solution* (System TA, p. 167). After development, remove the plate from the tank and dry under a stream of cold air until the plate no longer smells of ammonia. (Avoid using hot air to dry the plate as this can volatilise certain drugs.)

Alternatively, System TB (p. 167) or System TC (p. 167) may be used. For these systems, plates impregnated with potassium hydroxide are used. *Location Reagents.* Examine the plate under ultraviolet light. Cover columns 3 to 8 with a glass plate and spray

columns 1 and 2 with *acidified iodoplatinate solution*. Violet or blue colours are given by most basic drugs.

Cover columns 1 and 2 and 5 to 8 with glass plates, and spray columns 3 and 4 lightly with *Mandolin's reagent*. Various colours are given by many basic drugs (p. 137).

Cover columns 1 to 4 and 7 and 8, and spray columns 5 and 6 lightly with 9M sulphuric acid. Most phenothiazines are extensively metabolised, and urine extracts yield a number of spots on the chromatogram with colours ranging from pink to blue.

If a pure solution of a suspected drug has been applied to column 7, spray this and column 8 with a reagent with which it is known to react. Alternatively, if the Rf values and spray reagent reactions derived from columns 1 to 6 suggest the presence of a drug for which a further detection reagent exists, use this reagent on column 8 to obtain additional evidence. Details of Rf values and spot colours are given in Table 4.

Acidified iodoplatinate solution reacts with many basic drugs to give violet or blue colours. False positive reactions can occur with endogenous urine components; urine extracts from heavy smokers contain nicotine, the metabolites of which coalesce to give a brown spot. Mandolin's reagent reacts with fewer compounds, but gives more distinct colours, and some spots exhibit characteristic fluorescence under ultraviolet light. The presence of drug metabolites in urine extracts can result in a characteristic pattern of spots on the chromatogram.

Table 4. TLC data for some common basic drugs

	<i>TA</i>	<i>TB</i>	<i>TC</i>		<i>visible</i>	<i>UV (350 nm)</i>	
Imipramine	48	49	23	violet	blue	quenches	Desipramine; a second metabolite sometimes occurs between imipramine and desipramine
Methadone	48	61	20	pink (grey rim)	—	—	Methadone degradation product at Rf 15
Procydiline	48	63	31	violet	—	—	
Thioridazine	48	43	30	brown (blue rim)	blue (violet rim)	quenches	Pair of blue spots, with pink spots above and below with <i>Mandolin's reagent</i>
Chlorpromazine	49	49	35	violet (blue rim)	pink	yellow (weak)	Many, which give pink or blue spots with 9M sulphuric acid
Promethazine	50	37	35	violet (blue rim)	pink	—	One, below the parent drug
Quinine	50	2	11	violet	—	blue (strong)	One immediately below and one immediately above the parent drug; both strongly fluoresce
Amitriptyline	51	55	32	violet	violet	yellow (violet centre)	Nortriptyline; a second metabolite sometimes occurs between amitriptyline and nortriptyline
Clomipramine	51	54	34	violet	blue	quenches	One or two, both below the parent drug
Dothiepin	51	50	42	red (blue rim)	white	blue (weak)	One or two, both below the parent drug
Doxepin	51	52	37	violet	grey	blue (orange rim)	One or two, both below the parent drug
Pethidine	52	37	34	violet	—	—	One, below the parent drug
Dibenzepin	54	20	35	violet	blue	quenches	Two, both just below the parent drug
Nicotine	54	39	35	brown	—	—	Metabolites coalesce to give spot at Rf 60
Opipramol	54	6	22	blue	yellow	green	
Diphenhydramine	55	45	33	violet	—	—	One or two, both just below the parent drug
Orphenadrine	55	48	33	violet	yellow	blue	One, below the parent drug and with the same reactions to <i>Mandolin's reagent</i>
Chlorprothixene	56	51	51	violet	pink	orange	
Cyclizine	57	49	41	violet (blue rim)	—	—	One, below the parent drug
Mianserin	58	39	58	blue	violet	quenches	Two, below the parent drug
Butriptyline	59	61	48	pink	grey	green	One or two, both below the parent drug
Trimipramine	59	62	54	violet	blue	quenches	One or two, both below the parent drug
Carbamazepine	60	4	56	—	yellow (blue rim)	green (strong)	
Pentazocine	61	15	12	violet	grey	white	
Dextropropoxyphene	68	59	55	violet	grey	—	Several; one at Rf 40 which gives a blue streak with acidified <i>iodoplatinate solution</i> ; the parent drug is rarely seen in urine extracts
Lignocaine	70	35	73	blue	—	—	
Bucizine	75	61	83	red	—	—	

* Lignocaine is present as a local anaesthetic in various catheter lubricants; urine samples are frequently contaminated with it.

An alternative sequence of spray reagents, and alternative reference compounds, are given for Systems TA, TB, and TC on p. 167, and a comprehensive list of R_f values in these systems will be found in the indexes to Thin-layer Chromatographic Data in Part 3.

Detection of Benzodiazepines in Urine

This test relies on the hydrolysis of benzodiazepines or their metabolites to the corresponding amino-benzophenones. The product is extracted, chromatographed, and detected by the formation of an azo-dye (Bratton Marshall reaction).

Reference Solution. Prepare a solution containing 10 mg of oxazepam and 10 mg of nitrazepam in 100 ml of 1 N hydrochloric acid.

Method. Take two 20-ml screw-capped glass bottles (McCartney bottles) and to the first add 10 ml of the urine and 3 ml of *hydrochloric acid*, and to the second add 9 ml of 'blank' urine, 1 ml of the reference solution, and 3 ml of *hydrochloric acid*. Screw on the caps and heat the bottles in a boiling water-bath for 15 minutes. Cool the solutions, add to each bottle 10 ml of petroleum spirit (b.p. 40°–60°), shake for 5 minutes, and centrifuge. Transfer the solvent layers to 10-ml conical test-tubes, evaporate to dryness under a stream of air or nitrogen, and dissolve the residues in 0.1 ml of methanol. Divide a TLC plate (silica gel G, 250 µm) into two equal columns and apply 50 µl of each extract to the plate. Develop the plate in a tank containing a 4:1 mixture of chloroform: acetone (System TD, p. 168). After development, dry the plate in a stream of cold air.

Location Reagents. Spray the plate with the following reagents in the sequence shown, drying the plate under warm air after each application.

1. 9M sulphuric acid (spray lightly)
 2. A freshly prepared 1% solution of sodium nitrite
 3. A 5% solution of ammonium sulphamate
 4. *N*-(1-naphthyl)ethylenediamine solution
- Chlordiazepoxide, oxazepam, and the metabolites of diazepam and medazepam are hydrolysed to 2-amino-5-chlorobenzophenone, which forms a violet dye with the reagents. The test does not distinguish, therefore, between these drugs. The test will detect benzodiazepines in urine at therapeutic concentrations but it is not specific. Any compound that yields an aryl amino group on hydrolysis, e.g. phenylbutazone, will respond to the test.

SCHEME 2

Direct Tests on Urine, Stomach Contents, and Blood

Carry out the direct tests described under Scheme 1 (p. 4).

Extraction of Urine

To 10 ml of urine add sufficient *phosphoric acid* or tartaric acid to adjust the pH to 3, extract with two 30-ml portions of ether, combine the ether extracts, wash with 5 ml of water, add the washing to the sample, and retain the aqueous solution for later extraction. Extract the combined ether extracts with 5 ml of saturated sodium bicarbonate solution and retain the aqueous solution for possible examination for the presence of salicylate (Strong Acid Fraction A). Extract the ethereal solution with 5 ml of 0.5M sodium hydroxide and retain the extract for examination for the presence of barbiturates and other weakly acid substances (Weak Acid Fraction B)—see Table 5.

Wash the ethereal solution with water, discard the washing, dry the solution with anhydrous sodium sulphate, and evaporate to dryness. The residue may contain neutral drugs (Neutral Fraction C)—see Table 5.

To the aqueous solution retained after the first extraction add sufficient *dilute ammonia solution* to adjust the pH to 8, extract with two 10-ml portions of chloroform, wash the combined extracts with water, filter, add a little tartaric acid to prevent the loss of volatile bases, and evaporate to dryness. The residue may contain basic drugs (Basic Fraction D)—see Table 5.

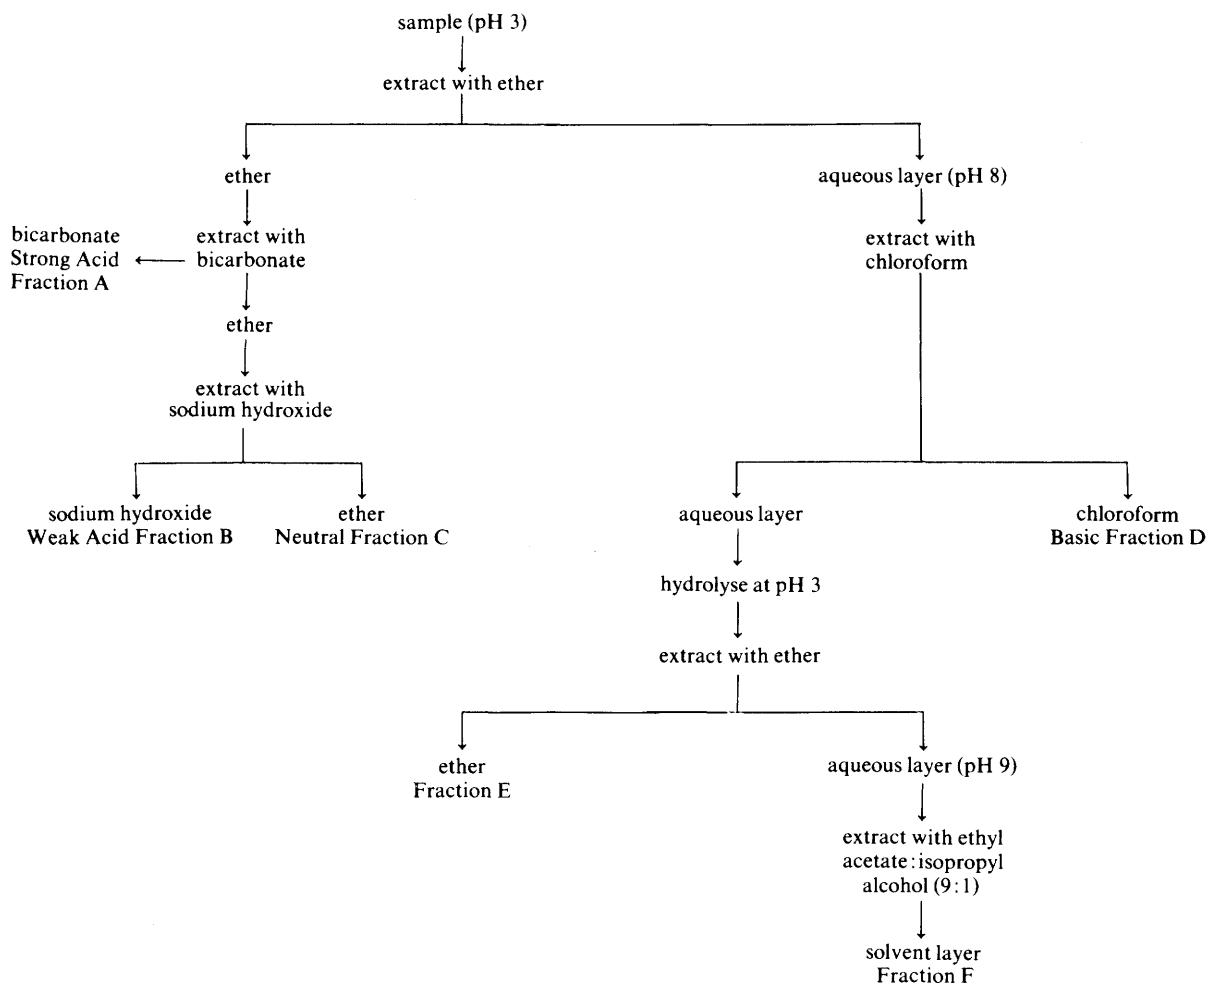

Adjust the aqueous solution obtained after extraction of Fraction D to pH 3 by the addition of *hydrochloric acid*, heat at 100° for 30 minutes, cool, and extract with two 10-ml portions of ether. Reserve the aqueous solution. Wash the combined ether extracts with 5 ml of 0.5 M sodium hydroxide, and evaporate the ether to dryness. The residue may contain benzophenones (Fraction E)—see Table 5.

Adjust the reserved aqueous solution to pH 9, cool, extract with a mixture of ethyl acetate and isopropyl alcohol (9:1), and evaporate the solvent layer to dryness. The residue may contain opiates (Fraction F)—see Table 5.

Extraction of Stomach Contents

Any fragments of capsules or tablets or any powdery

Scheme for the extraction of drugs from urine and stomach contents

material should be removed and suspended in water for extraction. If the sample contains much food residue or mucus, stable emulsions will be produced during the extraction procedure and the following pre-treatment is necessary.

Add an excess of solid ammonium sulphate together with a few drops of 10% phosphoric acid, heat and stir well, and filter. The filtrate is then extracted by the method described for urine, above.

Extraction of Blood

Because blood, plasma, or serum samples are small and only a limited number of drugs may be easily detected and identified in them, this extraction procedure differs slightly from that for urine and stomach contents.

The initial extraction is carried out at pH 7.4 as many basic drugs are recovered by chloroform extraction at this pH. As a result, the substance looked for is most likely to be found in either fraction B or C, and preparation of fraction D is only necessary either to ensure that nothing has been missed or where no drug has been found in fractions B and C.

To 4 ml of the sample add 2 ml of *phosphate buffer* (pH 7.4) and 40 ml of chloroform, shake vigorously, add about 2 g of anhydrous sodium sulphate, and shake again to produce a solid cake. Decant the chloroform through a filter, extract the cake again with a further 20 ml of chloroform, and combine the chloroform extracts. Retain the sodium sulphate cake.

Table 5. Drugs commonly taken in overdosage, which may be found in the various fractions obtained in the extraction process.

<i>Fraction A</i>		<i>Fraction C</i>		<i>Fraction D</i>	<i>Fraction E</i>
Salicylates	Caffeine	Meprobamate	Amitriptyline	Lorazepam	Benzodiazepines
(Phenytoin)*	Carbromal (stomach contents only)	Methaqualone (blood only)	Amphetamine †	Maprotiline	(as benzo-phenones)
			Caffeine	Methadone	
<i>Fraction B</i>	Chlordiazepoxide (blood only)	Methyprylone	Chlordiazepoxide	Methaqualone	
Barbiturates		Nitrazepam (blood only)	Chlormethiazole	Mianserin	<i>Fraction F</i>
Chlorpropamide	Chlormethiazole		Chlorpromazine †	Morphine	Codeine
Glutethimide	Ethchlorvynol	Paracetamol	Clomipramine	Nitrazepam	Morphine
Paracetamol	Flurazepam (blood only)	Phenazone	Codeine	Orphenadrine	
Phenylbutazone		Temazepam	Desipramine	Oxprenolol	
Phenytoin	Glutethimide	(blood only)	Dextropropoxyphene	Phenelzine†	
	Lorazepam (blood only)	Theophylline	Diazepam	Propranolol	
			Dihydrocodeine	Quinine	
			Dothiepin	Temazepam	
			Doxepin	Theophylline	
			Ergot alkaloids	Thionidazine †	
			Flurazepam	Trimipramine	
			Imipramine		

* Phenytoin will be found in this fraction only after very vigorous extraction with sodium bicarbonate,

† These drugs may be undetected in the blood owing to the very low concentrations present, even after overdose

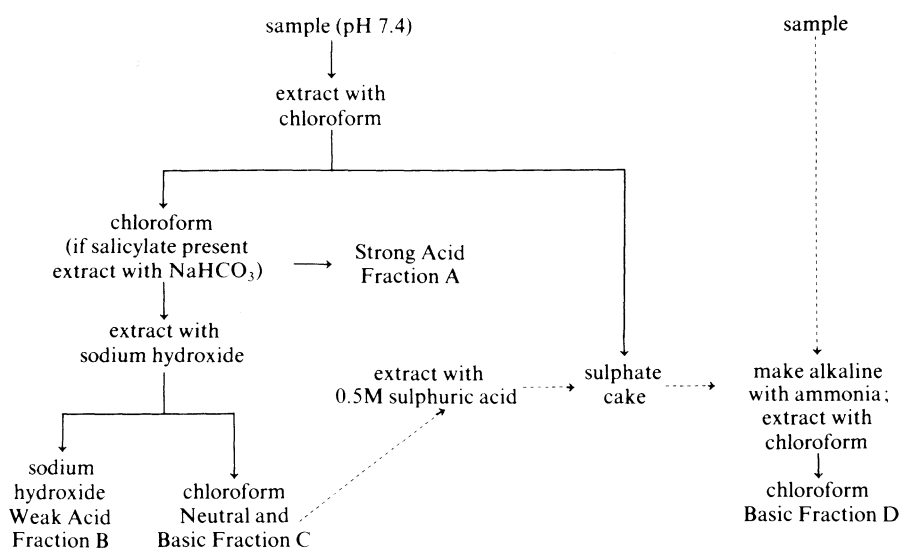

If salicylate has been found in the preliminary tests, it should be removed from the chloroform by extraction with sodium bicarbonate (Strong Acid Fraction A).

To the chloroform extracts add 8 ml, equivalent to twice the volume of sample taken, of 0.5M sodium hydroxide, shake for 2 minutes, and centrifuge. The sodium hydroxide solution may contain barbiturates and other weakly acid substances (Weak Acid Fraction A) see Table 5.

Wash the chloroform solution with a little water, discard the washing, dry the chloroform with anhydrous sodium sulphate, filter, and evaporate to dryness. The residue may contain neutral drugs together with a number of bases (Neutral and Basic Fraction C)—see Table 5.

If sufficient of the original sample is available, make a further portion alkaline with *dilute ammonia solution*, extract with two 10-ml portions of chloroform, dry the chloroform with anhydrous

Scheme for the extraction of drugs from blood, serum, or plasma

sodium sulphate, and evaporate to dryness. The residue may contain basic drugs (Basic Fraction D)—see Table 5.

If there is not sufficient of the original sample for this extraction, the following procedure may be carried out. After fraction C has been examined by the methods described below, dissolve any remaining residue in chloroform and extract with 0.5M sulphuric acid. Add this extract to the sodium sulphate cake retained after the first extraction, make alkaline with *dilute ammonia solution*, and extract with two 10-ml portions of chloroform. Dry the chloroform with anhydrous sodium sulphate and evaporate to dryness. The residue may contain basic drugs (Basic Fraction D)—see Table 5.

Ultraviolet Spectrophotometry of Fractions

The analyst should familiarise himself with the ultraviolet absorption of normal samples of urine, stomach contents, and blood; endogenous substances may interfere with the spectra of any drugs that may be present.

EXAMINATION OF FRACTION B

Barbiturates are a frequent cause of serious poisoning and should be sought first in samples from unconscious patients. The ultraviolet method given below will give a clinically acceptable quantitative result for the blood-barbiturate concentration; the method also permits the detection of other compounds in fraction B.

The method does not distinguish between the common 5,5-substituted barbiturates. If the physician proposes to institute a forced alkaline diuresis or haemodialysis, it is essential to confirm the presence of a long-acting barbiturate (e.g. barbitone, phenobarbitone) by thin-layer chromatography or gas chromatography.

Scan the fraction B extract from 220 to 400 nm against 0.5M sodium hydroxide as the blank. Particularly note the absorbance reading at 255 nm at this pH of 13.

Add 1 ml of a 16% solution of ammonium chloride to the sample and blank solutions and re-scan at this lower pH of 10. Particularly note the absorbance at 240 and 255 nm.

Add a few drops of 10M sulphuric acid to both cells to give pH 2 or less, and re-scan, particularly noting the absorbance at 240 nm. When Spectrophotometry is complete, add the pH 2 solution to the remainder of fraction B, acidify the solution, extract with ether, pour the extract through a Whatman No. 90 filter paper, and evaporate to dryness. The residue is retained for chromatographic examination.

Table 6. Ultraviolet spectrophotometry of fraction B

Compound	Absorbance maximum		
	pH 13 nm	pH 10 nm	pH<2 nm
Chlorpropamide	232	—	232
Barbiturates			
<i>N</i> -methyl-substituted	246	246	end absorbance
5,5-substituted	254	239	end absorbance
Paracetamol	257	—	245
Phenylbutazone	264	264	237
Barbiturates, 5-substituted	303	—	285

Quantification of Barbiturates

If a 5,5-substituted barbiturate is present, the approximate concentration ($\mu\text{g/ml}$) in the original sample can be calculated in two ways:

1. (absorption at 255 nm of pH 13 solution)
— (absorption at 255 nm of pH 10 solution) \times 160
2. (absorption at 240 nm of pH 10 solution)
— (absorption at 240 nm of pH 2 solution) \times 88

If only a barbiturate is present, good agreement should be obtained from the two calculations. A marked difference between the two suggests the presence of some other substance. The factors given are a compromise; if greater accuracy is required, the modified procedure described by P. M. G. Broughton (*J. Biochem.*, 1956, 63, 207-213) can be used.

EXAMINATION OF FRACTION C

Dissolve the dry residue in 3 ml of dry methanol and scan the solution between 220 nm and about 320 nm, using methanol as the blank. If no absorbance peaks are detected, it is still possible that a substance with a weak ultraviolet absorbance is present and so the solution is then retained for chromatographic examination. If any absorbance peaks are detected, the solution is acidified by the addition of 2 drops of *hydrochloric acid* and the scan repeated. The ultraviolet spectra of basic compounds extracted from blood at pH 7.4 may differ

Table 7. Ultraviolet Spectrophotometry of fraction C

Compound	Absorbance maximum	
	Neutral nm	Acid nm
Lorazepam	230	230 (316)
Methaqualone	265 (306)	234 (269)
Temazepam	230 (314)	237 (284)
Flurazepam	—	240 (284)
Phenacetin	244	244
Chlordiazepoxide	247 (266)	246 (308)
Chlormethiazole	250	258
Caffeine	273	273
Nitrazepam	—	280

considerably from those of the pure compound because of the presence of lipid material and possibly of metabolites.

If the methanol solution has been acidified, dilute it with about ten volumes of water, make alkaline with *dilute ammonia solution*, extract with two 5-ml portions of chloroform, and evaporate the combined chloroform solutions to dryness. The residue is retained for chromatographic examination.

EXAMINATION OF FRACTION D Dissolve the residue in 4 ml of 0.05M sulphuric acid and scan the solution between 220 and 360 nm. Make the solution alkaline with *dilute sodium hydroxide solution* and again scan the solution. Extract the alkaline solution with chloroform, evaporate the extract to dryness, dissolve the residue in methanol, and scan this neutral solution. The solution is retained for chromatographic examination

Table 8. Ultraviolet spectrophotometry of fraction D

Compound	Absorbance maximum		
	Acid	Neutral	Alkaline
	nm	nm	nm

For data on other compounds see the index of Ultraviolet Absorption Maxima in Part 3.

Chromatography of Fractions

Evaporate to dryness the extracts for fractions B, C, and D, dissolve each in 100 µl of chloroform,

and examine by thin-layer chromatography as described for Scheme 1 (p. 7). For fraction B and fraction C use Systems TD, TE, or TF (p. 168), and for fraction D use Systems TA, TB, or TC (p. 167). Fraction E may be examined by gas chromatography using System GA (p. 192); retention indices for benzophenones are given on p. 196.

Fraction F may be examined by thin-layer chromatography using Systems TA, TB, or TC (p. 167), or by gas chromatography using System GA (p. 192). R_f values and retention indices for opiates are given on p. 174 and p. 198, respectively.

GAS CHROMATOGRAPHY FOR DRUG SCREENING

Gas chromatography is a useful adjunct to the schemes previously described. The fractions remaining from Scheme 2 can be examined directly by gas chromatography or, alternatively, the micro-extraction method, described below, can be used. The most generally useful system for screening is one using a dimethylsilicone stationary phase such as SE-30, OV-1, or OV-101. Volatile amines elute with a better peak shape on alkaline columns such as Apiezon L coated with potassium hydroxide.

Micro-extraction Method

Rapid gas chromatographic screening can be carried out using direct solvent extraction of small volumes of samples. Extractions are performed in small disposable test-tubes, and no transfer or evaporation of solvent is involved, so that drugs are not lost in the procedure. Accurate micro-pipetting and the use of internal standards enables quantification of drugs detected in serum or plasma samples.

Disposable test-tubes approximately 6 cm long with an internal diameter of 5 mm (Dreyer tubes or their equivalent) are used. Samples and aqueous reagents are dispensed using high-precision pipettes (Eppendorf or their equivalent); organic solvents are dispensed using a Hamilton gas-tight, Luer-fitting, glass syringe fitted with a Hamilton repeating mechanism and a stainless steel needle. A standard bench centrifuge (3000 rpm) is adequate for these procedures, but separations are achieved more quickly by using a high-speed (10 000 rpm) centrifuge, although the test-tube adaptors supplied may have to be drilled out to accept Dreyer tubes. The technique is simple, but the analyst should pay careful attention to detail, especially when withdrawing solvent extracts for chromatography.

Method. Dispense appropriate volumes of sample and reagents (e.g. 200 μ l of plasma and 50 μ l of chloroform) into duplicate test-tubes, and mix for 30 seconds, gently at first and then more vigorously. Centrifuge the tubes for 5 to 10 minutes at 3000 rpm (or 2 to 3 minutes at 10 000 rpm); if emulsions persist after centrifuging, these are readily dispersed by vigorously mixing for 10 seconds and then centrifuging again.

To withdraw an aliquot of the chloroform extract, draw 5 μ l of air into the syringe, pass the needle through the aqueous/solvent interface and into the chloroform phase, expel the air gently to dislodge any debris from the needle and draw up the required volume of chloroform, wipe the needle with a tissue, and inject the extract into the chromatograph.

Fig. 1. Chromatogram of a standard solution of barbiturates on System GF, together with tetraphenylethylene (TPE).

Barbiturates and Other Acidic and Neutral Drugs

The plasma or serum extract is examined on two independent columns using 2.5% SE-30 on Chromosorb G (System GA, p. 192), and 3% Poly A 103 on Chromosorb W HP (System GF, p. 195). Compounds are identified by reference to retention data derived by chromatographing a solution of the pure drugs in chloroform.

Reference Solutions. Prepare a chloroform solution containing 10 μ g/ml of each of barbitone, butobarbitone, amylobarbitone, pentobarbitone, quinalbarbitone, and tetraphenylethylene (internal standard), and inject 3 μ l on to both columns to obtain standard chromatograms (e.g. Fig. 1).

Method. To 100 μ l of the serum sample add 10 μ l of phosphate buffer (pH 5.6), and extract with 100 μ l of chloroform containing 10 μ g/ml of tetraphenylethylene using the micro-extraction method, above; inject 3 to 5 μ l of the chloroform extract on to both columns.

Identify any peaks which appear on the chromatograms by reference to the standard chromatogram and the retention data listed in Table 9; the index of Gas Chromatographic Data in Part 3 may also be consulted. Corroborative evidence must be obtained from both systems. For quantification, prepare standard solutions of the identified drug containing 0., 10, 20, 50, and 100 μ g/ml in plasma. Examine at least three standards by the same method as used for the sample. Duplicate analyses of samples and standards are essential.

Table 9. Retention indices of some acidic and neutral drugs

Compound	System GA	System GF
Barbitone	1497	2230
Allobarbitone	1606	2340
Butobarbitone	1665	2390
Butalbital	1668	2395
Amylobarbitone	1718	2430
Pentobarbitone	1740	2465
Vinbarbitone	1740	2495
Quinalbarbitone	1791	2510
Meprobamate	1796	2460
Glutethimide	1836	2315
Phenazone	1848	2445
Hexobarbitone	1857	2380
Phenobarbitone	1957	2960
Cyclobarbitone	1963	2825
Heptabarbitone	2058	2940
Methaqualone	2125	2580
Phenylbutazone	2365	2860

Extracts from plasma samples derived from patients intoxicated with glutethimide give rise to several peaks due to the presence of metabolites (see monograph for Glutethimide). Retention indices for other drugs in these two systems will be found in the index to Gas Chromatographic Data in Part 3.

The standard solutions of various drugs in plasma may be dispensed into aliquots of 0.5 ml, and stored frozen until required for use.

Measure the peak-height ratio of the drug to the internal standard for each extract, and construct a calibration curve by plotting the mean peak-height ratio against the known concentration of the drug. Read off the concentration of drug in the sample directly from the graph. Alternatively, calculate the mean calibration gradient from the standards and divide this into the mean peak-height ratio of the sample duplicates.

Standard solutions of drugs can also be prepared in chloroform and these can be injected directly on to the chromatograph. The solutions should contain 10, 20, 50, and 100 µg/ml of the drug together with 10 µg/ml of tetraphenylethylene; they can be stored at 4° in the dark when not in use. If these standards are used, account must be taken of the incomplete recovery of the individual drugs from plasma. Thus, having derived the apparent drug concentration in the sample by measurement of the peak-height ratio, this value should be multiplied by the appropriate recovery correction factor (Table 10).

Table 10. Correction factors for the recovery of acidic and neutral drugs from plasma

Allobarbitone	1.32	Hexobarbitone	1.10
Amylobarbitone	1.10	Meprobamate	1.56
Barbitone	2.33	Methaqualone	1.14
Butalbital	1.00	Pentobarbitone	1.10
Butobarbitone	1.20	Phenobarbitone	1.28
Cyclobarbitone	1.12	Phenylbutazone	1.25
Glutethimide	1.00	Quinalbarbitone	1.18
Heptabarbitone	1.15	Vinbarbitone	1.00

Basic and Neutral Drugs

The preferred sample for this analysis is stomach contents, since the quantities of drug present are normally higher than in a urine sample. Urine can be used, but a concomitant analysis by thin-layer chromatography is advisable. The extract from stomach contents or urine is examined on two independent columns using 2.5% SE-30 on Chromosorb G (System GA, p. 192), and 3% Poly A 103 on Chromosorb W HP (System GF, p. 195). Compounds are identified by reference to retention data derived by chromatographing a solution of pure drugs in chloroform.

Reference Solutions. Prepare chloroform solutions containing standard mixtures of drugs, all at concentrations of 10 µg/ml, and inject 3 µl on to both columns. The composition of these solutions and the appearance of the chromatogram are shown in Fig. 2.

Method. To 100 µl of stomach contents or urine add 50 µl of M sodium hydroxide and extract with 100 µl of chloroform containing 10 µg/ml of tetraphenylethylene by the micro-extraction method, above; inject 3 to 5 µl of the chloroform extract on to both columns.

Identify any peaks which appear on the chromatograms by reference to the standard chromatogram and to the retention data listed in Table 11; the indexes of Gas Chromatographic Data in Part 3

Fig. 2. Chromatogram of a standard solution of basic drugs on System GF, together with tetraphenylethylene (TPE).

may also be consulted. Corroborative evidence must be obtained from both systems. Note that when urine samples are analysed, two or more peaks may appear on the chromatogram due to characteristic metabolite patterns.

Amphetamines and Other Volatile Bases

The extract from stomach contents or urine is examined on two independent columns using 2.5% SE-30 on Chromosorb G (System GA, [p. 192](#)), and 10% Apiezon L with 2% potassium hydroxide on Chromosorb W HP (System GB, [p. 193](#)). Compounds are identified by reference to retention data derived by chromatographing a solution of pure drugs in chloroform.

Reference Solutions. Prepare chloroform solutions containing standard mixtures of drugs, all at concentrations of 5 µg/ml, and inject 3 to 5 µl on to both columns to obtain the standard chromatogram. **Method.** To 100 µl of stomach contents or 500 µl of urine add 100 µl of M sodium hydroxide, and extract with 100 µl of chloroform by the micro-extraction method (above); inject 3 to 5 µl of the chloroform extract on to both columns. Identify any peaks which appear on the chromatograms by reference to the standard chromatogram and to the retention data given on [p. 193](#). Corroborative evidence must be obtained from both systems.

Volatile Hypnotics

This procedure uses gas chromatography to identify and quantify chlormethiazole, ethchlorvynol, and

trichloroethanol in plasma. System GA (p. 192) may be used as an alternative to the system described below.

Reference Solution. Prepare a solution in chloroform containing 30 µg/ml of ethchlorvynol, 50 µg/ml of each of chlormethiazole and trichloroethanol, and 25 µg/ml of 2-methylnaphthalene (internal standard). Inject 3 µl of this solution on to the gas chromatographic column to obtain the standard chromatogram.

Method. Extract 100 µl of plasma with 100 µl of chloroform by the micro-extraction method (described above), and inject 3 to 5 µl of the chloroform extract on to the column, using the following system.

COLUMN. 2% w/w Carbowax 20M and 5% w/w potassium hydroxide on 80 to 100 mesh Chromosorb WHP.

COLUMN TEMPERATURE. 140°

CARRIER GAS. Nitrogen at 60 ml/min. Identify any peaks which appear on the chromatogram by reference to the standard chromatogram and to the retention data listed in Table 12.

Table 12. Retention data for some volatile hypnotic

Compound	Carbowax	System GA
	RRT	RI
Trichloroethanol	0.52	857
Ethchlorvynol	0.69	1030
2-Methylnaphthalene	1.00	—
Chlormethiazole	1.28	1230

For quantification, prepare standard solutions of the identified drug in chloroform using the concentrations shown in Table 13. Add to each solution 20 µg/ml of 2-methylnaphthalene as internal standard. The standard solutions can be stored at 4° protected from light.

Table 13. Standard solutions of volatile hypnotic drugs

Compound	Concentration µg/ml			
	10	20	30	40
Chlormethiazole	10	20	30	40
Ethchlorvynol	20	50	100	150
Trichloroethanol	50	100	150	200

Inject 3 to 5 µl of at least three of the standard solutions on to the column. Duplicate analyses of samples and standards are essential. Measure the peak-height ratio of the drug to the internal standard for each solution, and construct a calibration curve by plotting the mean peak-height ratios against the known concentrations of the drugs. Read off the apparent concentration of drug in the sample directly

from the graph. The values for each duplicate sample extract should agree to within 10%; if the difference is greater, further duplicates should be extracted.

Alternatively, calculate the mean calibration gradient from the standard solutions and divide this into the mean peak-height ratio of the sample. The mean apparent drug concentration should be multiplied by the appropriate recovery correction factor in order to take account of the incomplete recovery of the individual drugs from plasma. These correction factors are, for chlormethiazole 1.04, for ethchlorvynol 1.05, and for trichloroethanol 1.33.

Tests for Specific Compounds and Groups of Compounds

ALCOHOLS

Ethanol is frequently taken at the same time as other drugs and can intensify the action of depressant drugs. A blood-ethanol determination assists in distinguishing this from normal alcoholic intoxication; it is also useful in the clinical assessment of unconscious patients admitted with head injuries and smelling of drink. Children are particularly at risk from hypoglycaemia which may follow ingestion of alcohol.

Methanol is available in a variety of commercial products (antifreeze preparations, windscreen-washer additives, duplicating fluids). Poisoning is often associated with a delayed onset of coma, marked metabolic acidosis, electrolyte imbalance, and hyperglycaemia, with a raised serum amylase. Therapy with ethanol infusions must be instituted without delay.

A qualitative test for alcohols in urine or blood is given on p. 4. Alcohols are preferably detected and measured in blood by gas chromatography, see below. An enzymatic assay kit for ethanol in blood is available (see Reagent Appendix).

CONFIRMATION OF METHANOL

To 1 ml of urine add 1 drop of 2.5% potassium dichromate in 50% sulphuric acid and allow to stand at room temperature for 5 minutes. Add 1 drop of ethanol and a few milligrams of chromotropic acid and then add *sulphuric acid* so that it forms a layer in the bottom of the tube. A violet colour at the interface indicates methanol. Note that formaldehyde will also give a positive reaction in this test.

Gas Chromatography of Alcohols

This procedure will identify and quantify the common alcohols in blood and urine. The column used is 0.3% Carbowax 20M on Carbopak C. The system is the same as System GI for Solvents and Other Volatile Compounds (p. 199) except that for this purpose it is operated isothermally at 120°.

identification of alcohols

Reference Solution. Prepare an aqueous solution containing 0.2 mg/ml of each of ethanol, methanol, isopropyl alcohol, and propanol, and inject 1 µl on to the column. The retention data for these compounds are listed in Table 14.

Method. Add 50 µl of whole blood or urine to 0.5 ml of distilled water in a stoppered test-tube, mix in a vortex mixer, and inject 1 µl on to the column. Identify any peaks which appear by reference to the standard chromatogram.

Table 14. Retention times of alcohols relative to propanol

Water	0.30	Isopropyl alcohol	0.79
Methanol	0.36	Propanol	1.00
Ethanol	0.50		

QUANTIFICATION OF ETHANOL OR METHANOL IN BLOOD OR URINE

Standard solutions should be prepared at least once a week and stored at 4°. Hamilton dispensers should be used to deliver accurate small volumes of the solutions, and great care should be taken to avoid cross-contamination of solutions if the same dispenser is used for different solutions.

Internal Standard Solution. Add 100 µl of propanol to 500 ml of distilled water. This gives a solution containing 0.16 g/litre.

Standard Alcohol Solutions. Add 100 µl of dehydrated alcohol or of methanol to 100 ml of distilled water. Add 50 µl to 250 µl of this solution, in increments of 50 µl, to 1.0-ml aliquots of the internal standard solution in stoppered test-tubes. This gives standard alcohol solutions equivalent to 0.04, 0.08, 1.20, 1.60, and 2.0 g/litre.

Method. Add 50 µl of the blood or urine sample to 0.5 ml of the internal standard solution in a micro test-tube (Dreyer tube), mix for a few seconds, and inject 1 µl on to the column. The test samples should be analysed in duplicate.

Inject 1- µl aliquots of at least two of the standard alcohol solutions.

Measure the peak-height ratio of ethanol (or methanol) to that of the internal standard for each sample extract and each standard solution. Plot the

peak-height ratio value against the designated alcohol concentration for each standard, and use the mean peak-height ratio for the sample duplicates to read off the alcohol concentration in the sample.

Alternatively, divide the peak-height ratio for each standard by the designated alcohol concentration to obtain calibration gradient values. Take the mean of these, and divide this figure into the mean peak-height ratio value for the test sample, to give the alcohol concentration directly.

AMITRIPTYLINE AND OTHER TRICYCLIC ANTIDEPRESSANTS

In overdose, these drugs have a cardio-respiratory depressant action leading to hypoxia and either respiratory or metabolic acidosis. Deep coma and convulsions can occur.

Alkaline extracts of samples of urine or stomach contents may be examined by thin-layer chromatography using Systems TA, TB, or TC (p. 167). Alternatively, the samples may be examined by gas chromatography using Systems GA or GF (p. 192) together with the micro-extraction method (p. 14). High pressure liquid chromatography systems for antidepressants (Systems HA and HF) are described on p. 214.

Note that amitriptyline, imipramine, and other tertiary amines give rise to the corresponding demethylated metabolites in urine samples. Measurement of plasma concentrations of these drugs is rarely necessary and should only be carried out by specific gas chromatographic procedures.

AMPHETAMINES, OTHER STIMULANTS, AND ANORECTICS

These drugs can be analysed by thin-layer chromatography using Systems TA, TB, or TC (p. 167). However, samples of urine or stomach contents are best analysed by gas chromatography (p. 17).

BARBITURATES

Barbituric acid derivatives account for a high proportion of poisonings, the severity being related to the amount and type of barbiturate ingested. For example, blood concentrations of phenobarbitone or barbitone which do not cause unconsciousness would cause deep coma in the case of pentobarbitone or quinalbarbitone.

Gas chromatography applied to plasma or urine samples is the method of choice (p. 15), as this simultaneously identifies and quantifies the drugs. Alternatively, extract a urine sample with chloroform at acid pH, identify the barbiturate by thin-

layer chromatography (p. 7), and determine the concentration by ultraviolet spectrophotometry (p. 13). Chromatographic systems for barbiturates are described on p. 171 (thin-layer chromatography), p. 196 (gas chromatography), and p. 216 (high pressure liquid chromatography).

If more than 2 hours have elapsed since the overdose, barbiturates may have passed from the stomach to the small intestine; in these circumstances, stomach aspirate or washings may give negative analytical results.

BENZODIAZEPINES

Benzodiazepine tranquillisers are widely prescribed and therefore occur more frequently than any other type of drug in overdose cases. Fortunately, the effects of these drugs in overdose are usually mild, although they may have a synergistic effect when taken with alcohol or other drugs. They are extensively metabolised prior to excretion in the urine.

A thin-layer chromatographic method for their detection in urine is described on p. 10; the method cannot distinguish between the various benzodiazepines (other than nitrazepam), but this is rarely important in the acute clinical situation. Concentrations in plasma can be measured by gas chromatography with electron capture detection, but the technique is difficult due to the instability of some of the drugs and their metabolites. Chromatographic systems for benzodiazepines are given on p. 196 (gas chromatography), and p. 216 (high pressure liquid chromatography).

CARBON MONOXIDE

Common sources of carbon monoxide are automobile exhaust fumes, improperly maintained and ventilated heating systems, smoke from fires, and household gas (other than natural gas). The affinity of carbon monoxide for haemoglobin is about 240 times that of oxygen, so that poisoning can occur when only small quantities of the gas are present in the atmosphere. When patients are removed from the contaminated atmosphere, the carboxyhaemoglobin disappears rapidly, particularly if oxygen is administered. Only traces may remain by the time the patient reaches hospital and, therefore, carboxyhaemoglobin measurements are rarely justified in clinical toxicology.

A qualitative test for carbon monoxide in blood is given on p. 6.

Quantification of Carbon Monoxide in Blood

The following method is based on that of E. J. van Kampen and H. Klouwen, *Ned. Tidschr. Geneeskde*, 1954, 98, 161-164, and *Rec. Trav. Chim. des Pays Bas*, 1954, 73, 119-128.

The method depends on the fact that normal blood contains several forms of haemoglobin, e.g. the reduced form, the oxygenated form, and a small amount of methaemoglobin. If a reducing agent such as sodium dithionite is added to the blood, both the oxygenated form and the methaemoglobin are quantitatively converted to the reduced form, which has the visible spectrum B shown in Fig. 3. Carbon monoxide has a much greater affinity for haemoglobin than has oxygen, and carboxyhaemoglobin is not reduced by sodium dithionite. Thus, even when treated with sodium dithionite, carboxyhaemoglobin retains its normal twin-peaked spectrum, marked A in Fig. 3. The wavelength of

Fig. 3. Ultraviolet spectra of (A) carboxyhaemoglobin, (B) reduced haemoglobin, and (C) a blood sample from a patient poisoned with carbon monoxide.

maximum absorbance difference for spectra A and B is at 540 nm, whilst at 579 nm the spectra have the same absorbance (isosbestic point). The percentage carbon monoxide-saturation of a blood sample can be calculated from measurements of the absorbance at these wavelengths of the carbon monoxide-saturated sample (A), the carbon monoxide-free sample (B), and the untreated sample

(C), after reduction of each with sodium dithionite. *Method.* Dilute 0.2 ml of the blood sample (mixed well) with 25 ml of a 0.1 % solution of ammonia and divide the resulting solution into three approximately equal parts labelled A, B, and C. Saturate solution A with carbon monoxide by bubbling the gas through it in a wide container and at a rate which minimises frothing. A few minutes bubbling should suffice. Saturate solution B with pure oxygen for 10 minutes to displace all the strongly bound carbon monoxide.

Add a small amount of sodium dithionite to each of the solutions A, B, and C, and also to 10 ml of 0.1% ammonia solution, and mix well. Place matched 1-cm cells containing the ammonia solution into the sample and reference beams of a spectrophotometer which has been set to record between the wavelengths 500 and 650 nm, in the superimposed, repeat-scan mode on a range of 0 to 2 absorbance units. Record the baseline for the determination. Then record the absorbance spectra for solutions A, B, and C. Wash out the sample cell thoroughly between the recordings and wash the cell with a little of the solution whose absorbance is about to be recorded. If the blood sample was from a person who died from inhalation of carbon monoxide, a set of spectra as shown in Fig. 3 should be obtained. Measure the absorbances of each solution at 540 nm and 579 nm, and calculate the ratio of absorbance at 540 to that at 579 nm for each of the solutions A, B, and C.

The percentage carboxyhaemoglobin-saturation is calculated as follows:

$$\% \text{ saturation} = \frac{\text{ratio for C} - \text{ratio for B}}{\text{ratio for A} - \text{ratio for B}} \times 100$$

Approximate normal values for the ratios of absorbance are: saturated carboxyhaemoglobin 1.5, and reduced haemoglobin 1.1. Note that the haemoglobin content of blood can vary, and therefore the volume of diluent may also need to be varied. A dilution giving a maximum absorbance of about 1 is ideal. Carbon monoxide in blood may also be quantified using an automated visible spectrophotometer (IL 282 Co-oximeter, see Reagent Appendix), which utilises four wavelengths to measure haemoglobin, oxyhaemoglobin, carboxyhaemoglobin, and methaemoglobin in small blood samples. Reference standards are commercially available (see Reagent Appendix).

CARBROMAL

This bromureide derivative is considered obsolete but may still occur in cases of poisoning. The symptoms following overdose are similar to those of barbiturate poisoning.

Test for Carbromal and Other Organic Bromine Compounds

Acidify a portion of stomach contents with 2M hydrochloric acid, and extract with four times its volume of chloroform; evaporate the extract to dryness, dissolve the residue in 0.5 ml of ethanol, transfer the solution to a white porcelain dish, add 2 drops of 2M sodium hydroxide, and dry with gentle heat. Cool, add 2 drops of a 1% solution of fluorescein, 4 drops of *acetic acid*, and 4 drops of *strong hydrogen peroxide solution*, and evaporate to dryness on a boiling water-bath. A red colour, due to eosin, indicates the presence of carbromal, bromvaletone, or other organic bromine compounds.

CHLORMETHIAZOLE

Chlormethiazole is widely used as a sedative in the treatment of alcoholism but tolerance develops rapidly. However patients often stop taking the drug. If, following a bout of heavy drinking, a large dose of chlormethiazole is taken, the patient collapses into deep coma accompanied by respiratory depression, hypotension, and hypothermia.

Test for Chlormethiazole

To 2 ml of plasma add 0.5 ml of M sodium hydroxide, extract with 5 ml of chloroform, centrifuge, discard the aqueous phase, and filter the chloroform. Extract the filtrate with 2 ml of 0.1 M sulphuric acid, and scan the ultraviolet absorption of the acid solution between 200 and 300 nm. Chlormethiazole gives a well-defined absorbance maximum at 258 nm.

The above procedure may be used as the basis of *s*-quantitative determination. Alternatively, gas chromatography may be used (p. 17).

CHLORATES AND OTHER OXIDISING AGENTS

Sodium and potassium chlorates are popular weedkillers which are highly toxic after oral ingestion. Cyanosis and methaemoglobinaemia are common features of poisoning with these substances. A test for oxidising agents in stomach contents is given on p. 5.

ETHCHLORVYNOL

The clinical features of overdose with ethchlorvynol resemble those due to poisoning with other hypnotics, but coma is often prolonged and accompanied by severe respiratory depression. Ethchlorvynol has a pungent odour which is often detected in the stomach contents. A qualitative test for ethchlorvynol in stomach contents is given on p. 6. A gas chromatographic method for the quantification of ethchlorvynol in plasma is given on p. 17.

GLUTETHIMIDE

Glutethimide intoxication resembles that of barbiturates in many respects, but is characterised by a fluctuating state of consciousness which may be due to the production of the active derivative, 4-hydroxyglutethimide.

Test for Glutethimide

To 1 ml of blood or stomach contents add 10 ml of chloroform, shake gently for 5 minutes, centrifuge, and filter the chloroform layer through a Whatman No. 1 filter paper. To the filtrate add 2 ml of 0.5M sodium hydroxide, shake for 2 to 3 minutes, centrifuge, separate the chloroform layer, filter it into a dry tube, and evaporate to dryness. Dissolve the residue in 2 ml of methanol and scan the ultraviolet absorption of the solution from 220 to 270 nm. Glutethimide has a maximum at 235 nm. Add 2 drops of 10M sodium hydroxide and immediately scan the solution again. If glutethimide is present, the peak at 235 nm diminishes rapidly due to hydrolysis of the piperidine ring. Glutethimide can also be detected by thin-layer chromatography (p. 7). For quantification, gas chromatography is the method of choice (p. 15).

IRON

Poisoning with iron salts is extremely dangerous, particularly in young children. Rapid necrosis of the gastro-intestinal mucosa occurs, with haemorrhage and fluid and electrolyte loss. The absorbed iron rapidly exceeds the binding capacity of transferrin, and free iron accumulates in the serum. The determination of the serum-iron concentration is required when intravenous infusions of the chelating antidote (desferrioxamine) are given.

A green or blue colour in the vomit or stomach aspirate suggests the presence of iron salts. A qualitative test for the presence of iron salts in stomach contents is given on p. 5, and a quantitative

method to determine serum-iron concentration is given on p. 60.

Commercial serum-iron assay kits are available (see Reagent Appendix).

MEPROBAMATE AND OTHER CARBAMATES

Meprobamate causes coma, respiratory depression, and hypotension when taken in overdose.

Test for Carbamates in Stomach Contents

Acidify a portion of the sample with 2M hydrochloric acid, extract with four times its volume of chloroform, separate the chloroform layer, and evaporate to dryness. Dissolve the residue in 0.5 ml of ethanol and spot a 0.1-ml portion on to a filter paper; stain the spot with 0.01 ml of *furfuraldehyde solution*, allow to dry, and expose the paper to the fumes of hydrochloric acid for 2 to 3 minutes. A black spot indicates the presence of a carbamate. Meprobamate can be detected and quantified by gas chromatography (p. 15).

ORGANOPHOSPHORUS PESTICIDES

There are no simple direct chemical tests for organophosphorus compounds. The toxic effects are usually associated with depression of the cholinesterase activity of the body, and measurement of the plasma or serum cholinesterase can be used, therefore, as an indication of organophosphorus poisoning.

Plasma or serum cholinesterase (pseudocholinesterase) is inhibited by a number of compounds and can also be decreased in the presence of liver impairment. Erythrocyte cholinesterase (true cholinesterase) reflects more accurately the cholinesterase status of the central nervous system. However, pseudocholinesterase activity responds more quickly to an inhibitor and returns to normal more rapidly than erythrocyte-cholinesterase activity. Thus, measurement of pseudocholinesterase activity is quite adequate as a means of diagnosing acute exposure to organophosphorus compounds, but cases of illness which may be due to chronic exposure to these compounds should also be investigated by determining the erythrocyte-cholinesterase activity. A colorimetric method for this purpose has been reported (K.-B. Augustinsson *et al.*, *Clinica chim. Acta*, 1978, 89, 239-252).

A test for cholinesterase inhibitors in serum is given on p. 6.

Quantification of Cholinesterase Activity in Serum
Adjust the temperature of 3 ml of *dithiobisnitrobenzoic acid* solution to 25°, add 20 µl of the serum sample and 0.1 ml of a 5% solution of acetylthiocholine iodide, mix well, and record the absorbance of a 1-cm layer at 405 nm at 30-second intervals over a period of 2 minutes. If the change in absorbance exceeds 0.2 in 30 seconds, dilute the sample 1 in 10 with normal saline and repeat the measurements (the readings must then be multiplied by 10). The concentration of cholinesterase is calculated as follows:

$$\text{Cholinesterase (milliunits/ml)} = \frac{\text{change in absorbance in 30 seconds} \times 23\,400}{\text{change in absorbance in 30 seconds}}$$

Normal values for cholinesterase in serum are 1900 to 4000 milliunits/ml. Commercial kits for the determination of cholinesterase activity are available (see Reagent Appendix).

Alkyl phosphorus compounds can be detected in serum by performing the cholinesterase determination on (a) a sample of normal serum, (b) the test serum, and (c) 10 µl of normal serum + 20 µl of test serum. If a low value is obtained from (b), this could be due to a low cholinesterase from liver disease or other causes. A value for (c) which is lower than the sum of the results from (a) and (b) indicates the presence of an inhibitor. Usually, in organophosphorus poisoning, the result from (c) is lower than that from (a).

PARACETAMOL

Overdose of paracetamol can cause severe and sometimes fatal liver damage. Few symptoms appear on the first day after ingestion, although nausea and vomiting can occur. Liver-function tests become abnormal 12 to 36 hours after overdose, with raised concentrations of serum aminotransferase and bilirubin, and prolongation of the prothrombin time. Antidotes are available (oral methionine, intravenous acetylcysteine), but these are effective only when given within 12 hours of the overdose. The plasma-paracetamol concentration is a reliable indicator of the likelihood of liver damage (see monograph for Paracetamol).

A sensitive direct test on urine is described on [p.5](#)

Quantification of Paracetamol in Plasma by Colorimetry

After J. P. Glynn and S. E. Kendal, *Lancet*, 1975, 7, 1147-1148.

Standard Solutions. Dissolve 1 g of paracetamol in the minimum volume of dehydrated alcohol, and dilute to 100 ml with water to give a stock solution containing 10 mg/ml. This solution should be stored frozen. To 20-ml aliquots of normal plasma add 100, 200, 400, 600, and 800 µl of the stock solution to give standard solutions containing 50, 100, 200, 300, and 400 µg/ml of paracetamol. Note that paracetamol is unstable in plasma; fresh plasma standards should be prepared each week and stored at 4° when not in use.

Method. Prepare seven 10-ml centrifuge tubes each containing 2 ml of a 10% solution of trichloroacetic acid. To five of the tubes add 1 ml each of the five standard solutions, and to the other two tubes add 1 ml of normal plasma and 1 ml of the plasma sample respectively. Agitate each tube for a few seconds, and then centrifuge at 3000 rpm for 5 minutes to deposit the protein precipitate.

Prepare seven 30-ml tubes containing 1 ml of 6M hydrochloric acid and 2 ml of a 10% solution of sodium nitrite (freshly prepared); this procedure should be carried out in a fume cupboard.

Carefully remove 2 ml of the supernatant liquid from each of the centrifuge tubes, add to the appropriate 30-ml tube, and allow to stand for 2 to 3 minutes. To each of the tubes add, dropwise, 2 ml of a 15% solution of ammonium sulphamate to remove excess nitrous acid (vigorous frothing occurs), followed by 2 ml of 6M sodium hydroxide; mix for a few seconds to remove any gas bubbles, and measure the intensity of the yellow solutions at 450 nm against the plasma blank. Calculate the concentration of paracetamol in the sample by reference to a calibration curve prepared from the values for the standard solutions. Duplicate analyses of samples and standards should be carried out.

Paracetamol concentrations below 50 µg/ml cannot be measured accurately by this method; for such samples a chromatographic method should be used (see below).

Salicylic acid undergoes a similar reaction, but plasma containing 1000 µg/ml of salicylate yields a colour intensity equivalent to only 20 µg/ml of paracetamol. Samples contaminated with heparin which contains cresol as a preservative can give spurious results as high as 200 µg/ml.

Quantification of Paracetamol in Plasma by an Enzymatic Method

P. M. Hammond *et al.*, *Lancet*, 1981, 7, 391-392. This method is based on the enzymatic degradation

of paracetamol by an aryl acylamidase, to yield 4-aminophenol which then reacts with o-cresol in the presence of ammonia and copper ions to give a blue indophenol dye. This method is highly specific; common metabolites of paracetamol (glucuronide, sulphate, mercapturate) do not react. The limit of accurate measurement is approximately 10 µg/ml. The method is available in kit form (see Reagent Appendix).

Quantification of Paracetamol by High Pressure Liquid Chromatography

Standard Solutions. Prepare standard solutions of paracetamol as described in the colorimetric method, above.

Internal Standard Solution. A solution containing 125 µg/ml of N-propyl-4-aminophenol in methanol.

Method. To 50 µl of plasma, serum, or whole blood in a 1-ml polypropylene centrifuge tube add 100 µl of the internal standard solution, mix, and centrifuge for 2 minutes in a microcentrifuge. Examine 5 µl of the supernatant liquid by high pressure liquid chromatography, using the system described below, with ultraviolet detection at 240 nm.

COLUMN. ODS-silica (ODS-Hypersil, 5µm, 15 cm x 4.6 mm internal diameter).

ELUENT. Methanol: water:acetic acid:sodium acetate (200:800:5:5).

Examine the standard solutions by the same procedure.^z

Paracetamol metabolites, salicylic acid, and salicylic acid metabolites also elute from this system. Retention times relative to paracetamol for these substances in this system are;

Paracetamol glucuronide	0.30
Paracetamol sulphate	0.48
Gentisic acid	0.50
Paracetamol	1.00
Salicylic acid	1.22
Salicyluric acid	1.37
N-propyl-4-aminophenol	1.85

Quantification of Paracetamol by Gas Chromatography

A. Huggett *et al.*, *J. Chromat.*, 1981, 209, 67-76.

Standard Solutions. Prepare standard solutions of paracetamol in plasma as described for the colorimetric method, above.

Internal Standard Solution. A solution containing 200 µg/ml of N-butyryl-4-aminophenol in chloroform; it should be stored in the dark at 4°.

Acetylating Reagent. A freshly prepared mixture of

acetic anhydride: N-methylimidazole: chloroform (5:1:30).

Method. To 100 µl of plasma or serum in a small test-tube add 50 µl of the internal standard solution, 50 µl of *phosphate buffer (pH 7.4)*, and 20 µl of the acetylating agent. Mix for 30 seconds, and centrifuge at 7500 rpm for 3 minutes. Withdraw 3 to 5 µl of the chloroform extract and examine by gas chromatography using the system described below, and a flame ionisation detector. Examine the standard solutions by the same procedure.

COLUMN. 3% Apolane-87 on 100-120 mesh Chromosorb W HP, 1.5 m x 4 mm internal diameter glass column.

COLUMN TEMPERATURE. 235°

CARRIER GAS. Nitrogen at 40 ml/min.

Paracetamol and N-butyryl-4-aminophenol elute with retention times of approximately 2 minutes and 3 minutes, respectively.

PARAQUAT AND DIQUAT

Granular preparations usually contain 2.5% of paraquat and 2.5% of diquat; liquid preparations may contain 20% w/v of paraquat only. Treatment consists of reducing paraquat absorption by administering copious amounts of the adsorbents Fuller's Earth or bentonite, with cathartics. Active elimination techniques (forced diuresis, haemodialysis, charcoal haemoperfusion) may also be applied.

A plasma-paraquat assay is a reliable indicator of whether a dangerous amount of the herbicide has been ingested. Patients whose plasma concentrations do not exceed 2.0, 0.6, 0.3, 0.16, and 0.1 µg/ml at 4, 6, 10, 16, and 24 hours, respectively, after ingestion are likely to survive. The main use of an assay is in the prevention of overtreatment of patients who are not at risk.

Test for Paraquat and Diquat in Urine or in Stomach Contents

Paraquat and diquat are readily detected in urine or stomach contents by the test given on [p. 5](#).

This test may also be carried out by an alternative procedure in which the reducing reagent is prepared in encapsulated form. Mix together thoroughly 10 g of sodium dithionite, 6 g of disodium tetraborate and 25 g of sodium bicarbonate; pack the mixture into gelatine capsules (gauge 0) to produce about 40 capsules. To carry out the test, tip the contents of 1 capsule into 10 ml of urine or stomach contents, and shake to dissolve. A blue colour, due to the

reduction of paraquat to its free radical, indicates the presence of paraquat. A reference solution of paraquat (5 µg/ml) should be tested at the same time. The contents of the capsules are stable for at least 6 months at room temperature.

Quantification of Paraquat in Plasma by Colorimetry

After D. R. Jarvie and M. J. Stewart, *Clinica chim. Acta*, 1979, 94, 241-251.

Standard Solutions. Prepare standard solutions of paraquat in plasma containing 0, 0.1, 0.2, 0.5, 1.0, and 2.0 µg of paraquat ion per ml; store frozen until required.

Extraction Solvent. Mix 50 ml of water-saturated isobutyl methyl ketone with 50 ml of water-saturated isobutanol, and add 0.5 g of sodium dodecyl sulphate.

Method. To 2 ml of plasma in a 15-ml glass-stoppered centrifuge tube add 2 ml of water and 10 ml of the extraction solvent, mix gently for 5 minutes on a roller mixer, and centrifuge for 5 minutes at 3000 rpm. Carefully remove 8 ml of the solvent phase, transfer it to a second tube containing 0.8 ml of 2.5M sodium chloride, stopper the tube, shake vigorously for 5 minutes, and centrifuge for 2 minutes at 3000 rpm. Carefully remove the solvent phase, transfer 0.7 ml of the aqueous phase to a 4-ml glass tube, add 100 µl of a freshly-prepared 3% solution of sodium dithionite in 0.3M sodium hydroxide, shake the mixture briefly, transfer to a semi-micro quartz cuvette, and immediately scan the solution between 384 nm and 460 nm against a blank containing 0.7 ml of 2.5M sodium chloride and 100 µl of the sodium dithionite solution.

The absorbance due to paraquat is obtained by subtracting the reading at 460 nm from that at 397 nm. Results for standard solutions treated in the same way are plotted and the concentration in the sample is deduced from the calibration curve. The method is capable of measuring plasma-paraquat concentrations down to 0.05 µg/ml. If diquat is also present, this will be extracted and gives rise to additional small peaks between 430 and 460 nm. Corrections can be made for this, but the increase in paraquat concentration is small (10 to 15%) and is usually insignificant in clinical situations.

Quantification of Paraquat in Plasma by Radioimmunoassay

This is the most sensitive and specific method, and can measure plasma-paraquat concentrations as

low as 6 ng/ml. No interference with other bipyridyl herbicides occurs. For information see T. Levitt, *Proc. Analyt. Div. Chem. Soc.*, 1979, 16, 72-76, and D. Fatori and W. M. Hunter, *Clinica chim. Acta*, 1980 100, 81-90.

PHENOTHIAZINES

Tests on Urine

1. To 1 ml of urine add 1 ml of *FPN reagent*. A pink, red, orange, violet, or blue colour indicates the presence of a phenothiazine derivative. The colours are transient and should be observed immediately. Positive results can be obtained on urine samples from patients receiving therapeutic doses.

2. Mix together 98 ml of 30% sulphuric acid and 2 ml of *ferric chloride solution*, and add 1 ml of this reagent to 1 ml of urine. A pale pink colour deepening to blue indicates ingestion of thioridazine. Other phenothiazines can give colours, but the test is more sensitive than FPN reagent towards thioridazine.

Phenothiazines may be determined in urine by the thin-layer chromatographic method described on p. 7. Thin-layer chromatographic systems for phenothiazines are described on p. 174, gas chromatographic systems on p. 198, and high pressure liquid chromatographic systems on p. 219.

PHENYTOIN, PRIMIDONE, AND PHENOBARBITONE

These drugs are commonly prescribed in combination in the treatment of epilepsy. Symptoms of acute overdose simulate those of barbiturate poisoning. Laboratories which offer a routine therapeutic drug monitoring service for these drugs will have little difficulty in adapting their normal procedures to the occasional overdose case. These drugs can be measured simultaneously in plasma samples by gas chromatography using the method described for Barbiturates and other Acidic and Neutral Drugs (p. 15), except that the column used is 2% SP-2110 and 1% SP-2510-DA on Supelcoport (System GE, p. 194).

Two standard plasma solutions are used, the first containing 50 µg/ml of phenobarbitone and 20 µg/ml each of primidone and phenytoin, and the second containing 100 µg/ml of phenobarbitone and 50 µg/ml each of primidone and phenytoin. The internal standard used is either 5-methyl-5-phenylhydantoin or 5-p-methylphenyl-5-phenylhydantoin.

A high pressure liquid chromatographic system for anticonvulsants is described on [p. 215](#).

QUINIDINE AND QUININE

These stereoisomers have similar toxic properties, severe overdose resulting in cardiac arrhythmias and visual disturbances which sometimes lead to permanent blindness.

Test on Urine for Large Amounts

Make 20 ml of urine alkaline with *dilute ammonia solution*, extract with an equal volume of chloroform, shake the chloroform extract with 3 ml of 10% sulphuric acid, and centrifuge. A blue fluorescence in the acid phase, more noticeable under ultraviolet light, suggests the presence of quinidine or quinine.

Quantification of Quinine and Quinidine by Fluorescence Spectrophotometry

Standard Solutions. Prepare solutions in plasma containing 5, 10, and 20 µg/ml.

Method. To 200 µl of the plasma sample in a 10-ml conical test-tube add 40 µl of 2M tris(hydroxymethyl)methylamine and 4ml of a mixture of chloroform and isopropyl alcohol (3:1); mix for 30 seconds, and centrifuge for 5 minutes. Carefully transfer the solvent layer to a second test-tube containing 4 ml of 0.05M sulphuric acid, mix, centrifuge for 5 minutes, and carefully transfer about 2ml of the acid layer to a 1-cm quartz fluorescence cuvette. Excite the extract at 350 nm and measure the intensity of emission at 450 nm. The standard plasma solutions are processed similarly at the same time.

SALICYLIC ACID

Salicylic acid is often found as the hydrolysis product of aspirin or other salicylic acid derivatives. Aspirin is one of the most commonly used analgesics and accounts for a high proportion of serious accidental or deliberate poisonings. Ingestion of more than fifty 300-mg tablets can cause serious toxicity in adults. The ingestion of methyl salicylate is less common but is particularly dangerous due to rapid absorption; one 5-ml spoonful of methyl salicylate is equivalent to 12 aspirin tablets. Plasma-salicylate measurements are a reliable guide to the severity of poisoning (see the monograph for Salicylic Acid).

Respiratory alkalosis and metabolic acidosis are characteristic features of salicylate poisoning, and

blood-gas analyses (oxygen and carbon dioxide) are mandatory. Loss of consciousness is rare except in cases of very severe poisoning with acidaemia. Forced alkaline diuresis is considered if plasma-salicylate concentrations exceed 500 µg/ml, and if marked clinical features or acidosis are present.

Tests on Urine and Stomach Contents

Tests for the presence of salicylates in urine or stomach contents are given on [p. 4](#) and [p. 5](#), respectively.

Quantification of Salicylic Acid in Plasma by Colorimetry

Standard Solutions. Prepare aqueous solutions containing 0, 200, 500, and 800 µg/ml of salicylic acid; they should be stored frozen when not in use.

Method. Place 1 ml of the plasma sample in a 15-ml centrifuge tube, add 5 ml of *Trinder's reagent*, mix for 30 seconds, centrifuge for 5 minutes at 2400 rpm, and measure the colour intensity of the supernatant liquid at 540 nm. Determine the concentration by comparison with the standard solutions.

Quantification of Salicylic Acid in Plasma by High Pressure Liquid Chromatography

Salicylic acid may be determined by the method described for paracetamol, [p. 24](#), using standard solutions in plasma or whole blood containing 0, 100, 200, 400, and 800 µg/ml of salicylic acid.

THEOPHYLLINE

Serious overdose with this xanthine bronchodilator can provoke serious hypotension, cardiac arrhythmias, and convulsions. These symptoms indicate a poor prognosis, particularly in elderly patients. Symptoms of poisoning after a high dose of a slow-release preparation can be delayed for several hours as the drug gradually accumulates to toxic concentrations. Patients with plasma concentrations greater than 60 µg/ml may require charcoal haemo-perfusion.

Commercial immunoassay kits are available for the determination of theophylline in serum or plasma.

Quantification of Theophylline in Plasma by High Pressure Liquid Chromatography

Internal Standard Solution. A solution containing 5 µg/ml of 8-chlorotheophylline in M sodium acetate.

Method. To 50 µl of plasma (or serum) in a 10-ml

centrifuge tube add 100 μ l of internal standard solution, and 2 ml of a mixture of chloroform and isopropyl alcohol (9:1); mix, and centrifuge at 3000 rpm for 5 minutes. Transfer the solvent phase to a second tube, and evaporate to dryness under a stream of air or nitrogen at 50°. Examine the residue by high pressure liquid chromatography, using the system described below, by dissolving the residue in 20 μ l of the eluent and injecting 10 μ l on to the column.

COLUMN. ODS-silica (ODS-Hypersil, 5 μ m).

ELUENT. Mix together 100 ml of methanol, 30 ml of tetrahydrofuran, and 900 ml of water, add 1 ml of *acetic acid*, and adjust the pH to 5.6 by the addition of *sodium hydroxide solution*.

The adjustment of the pH is critical for the separation of 8-chlorotheophylline. UV detection is at 280 nm. Other xanthines and xanthine metabolites also elute from this system. Retention times relative to theophylline are: 3-methylxanthine, 0.49; theobromine, 0.63; paraxanthine, 0.88; caffeine, 1.36; 8-chlorotheophylline, 1.46.

TRICHLORO-COMPOUNDS

Chloral hydrate and dichloralphenazone are metabolised to trichloroethanol, which is the major active product of these drugs. Trichloroethanol can be determined in plasma or serum by gas chromatography (p. 17).

A test for the presence of trichloro-compounds in urine is given on p. 5.

Screening for Drugs of Abuse

Analytical methods for use in the investigation of drug dependence are given below, together with techniques for the detection of other substances which may be abused. These include volatile solvents (p. 31), diuretics (p. 32), and laxatives (p. 32).

EXTRACTION OF URINE FOR DEPENDENCE-PRODUCING DRUGS

Patients attending a clinic for the treatment of drug dependence are routinely asked for a sample of urine for analysis. Thereafter, periodic tests are carried out as a check on whether the patient is complying with prescribed medication or is also taking drugs obtained illicitly. Laboratories which offer a routine service to treatment clinics may have to cope with batches of 50 or more samples at a time. The scheme

described below has been designed with this in mind, although single samples can be dealt with in the same way. Two methods are described, one using direct solvent extraction, and the other a solid-liquid elution system which is quicker and more amenable to processing a large number of samples. In both methods, a pH of 9 is selected to ensure good extraction of morphine. In strongly alkaline conditions, morphine forms a phenolic ion which has poor solubility in the solvent used.

Solvent Extraction

Place 10 ml of urine in each of two 20-ml glass bottles fitted with plastic screw-caps (McCartney bottles), and to one bottle add 1 to 2 ml of M sulphuric acid and to the other add sufficient sodium bicarbonate to saturate the solution. Label the bottles A and B (acids and bases) respectively. Fill each bottle with a mixture of chloroform and isopropyl alcohol (9:1), screw on the caps, shake for 5 minutes, and centrifuge for 5 to 10 minutes. Aspirate the top aqueous phase using a Pasteur pipette connected to a water-operated vacuum pump, filter the chloroform extracts through phase-separating paper to remove residual water, and collect the filtrates in 10-ml conical test-tubes;

evaporate to dryness under a stream of air or nitrogen, reconstitute the residues in 100 μ l of chloroform, and analyse by thin-layer chromatography.

Solid-liquid Extraction

This method uses commercially-prepared columns containing granules of diatomaceous earth with a large pore volume (e.g. Tox Elut, Extrelut, see Reagent Appendix). The urine sample is poured on to the column followed by organic solvent which percolates rapidly through the granules and extracts lipid-soluble drugs and metabolites. Panicle material, pigments, and polar metabolites are retained in the diatomaceous earth. Further purification of the organic extract takes place as it passes through the dry region of the column.

Add 20 ml of urine to the column (use a ready-buffered column at pH 9), and allow the sample to soak into the packing material for 2 minutes. Place a 50-ml test-tube under the column outlet, and pour 15 ml of a mixture of chloroform and isopropyl alcohol (9:1) on to the column. When the first elution is complete, add a further 15 ml of the solvent and collect the eluate in the same test-tube.

Insert into the top of the column a hollow rubber stopper connected by a rubber tube to a pressure bulb, and apply gentle pressure to discharge residual solvent. Place the tube containing the eluates in a beaker of hot water and evaporate the extract to dryness under a stream of air. Dissolve the residue in 50 µl of the solvent mixture and analyse by thin-layer chromatography.

In this system, weakly acidic drugs (barbiturates), as well as neutral and basic drugs, are extracted together at pH 9. Phenobarbitone extraction is poor (recovery approximately 20%), but is still sufficient to allow detection of the drug in dependent patients.

THIN-LAYER CHROMATOGRAPHY OF DEPENDENCE-PRODUCING DRUGS

Use plastic sheets or glass plates (20 x 20 cm), coated with silica gel (250 µm thick). Score vertical lines on the plates in order to bring about an even movement of the developing-solvent front; if large batches of samples are being processed, each plate can be scored to produce 12 columns to accommodate the reference mixture and 11 sample extracts. Score a horizontal line about 10 cm from the bottom of the plate to mark the distance to be travelled by the solvent front. Four plates are required.

Acidic Drugs

Reference Solution. Prepare an ethanolic solution containing 1 mg/ml of each of amylobarbitone and phenobarbitone.

Method. Apply 25 µl of the reference solution to the first column of the plate, and apply 25 µl of the acidic extract from the solvent extraction method, or of the column extract, to the next column on the plate. Use a 100-µl gas-chromatography syringe for the application, taking great care to wash the syringe several times with chloroform between the application of each extract. Develop the plate in a tank containing chloroform: acetone (4:1) (System TD, p. 168). After development, remove the plate and dry under a hot-air blower.

Location Reagents. Spray the plate with *mercurous nitrate spray*. Barbiturates give black spots initially which turn chalky-white as spraying is continued. This reagent is quite sensitive, 1 µg of a barbiturate being easily discerned. Glutethimide and phenytoin (sometimes used to control withdrawal symptoms) also react with this spray. Rf values for some common acidic drugs of abuse are given in Table 15. System TE (p. 168) can also be used.

Table 15. TLC data for some common acidic drugs of abuse

Compound	System TD	System TE
Phenytoin	33	36
Phenobarbitone	47	28
Amylobarbitone	52	36
Quinalbarbitone	55	44
Glutethimide	63	78

Basic Drugs

Reference Solution. Prepare an ethanolic solution containing 1 mg/ml of each of morphine, codeine, methadone, and cocaine.

Method. Apply 25 µl of the reference solution to the first column of each of three plates. Divide the basic extract from the solvent extraction method, or the remainder of the column extract, equally between the three plates. Develop one plate in a tank containing 100 ml of methanol: *strong ammonia solution* (100:1.5) (System TA, p. 167). Develop the other two plates in a tank containing ethyl acetate: methanol: *strong ammonia solution* (85:10:5) (System TE, p. 168). After development, remove the plates from the tanks and dry under a stream of cold air until they no longer smell of ammonia. Avoid using a hot-air blower as methadone may volatilise.

Location Reagents. Spray the plate developed in System TA, and one of the plates developed in System TE, with *acidified iodoplatinate solution*. Lightly spray the remaining plate developed in System TE with 9M sulphuric acid; phenothiazine drugs and their metabolites give pink, red, or blue spots. Overspray with *acidified iodoplatinate solution*; the presence of the acid deepens the blue colour produced when morphine reacts with iodoplatinate solution, and this increases the sensitivity of detection of this compound.

The three plates should be examined side by side immediately after spraying. A list of Rf values in the two systems for the major narcotic drugs and their metabolites is given in Table 16. However, many other basic drugs will react with acidified iodoplatinate solution. Rf values for many substances in these two systems will be found in the index to Thin-layer Chromatographic Data in Part 3. Thin-layer chromatographic data for narcotic analgesics in other systems is given on p. 174.

Interfering Substances

Heavy smoking is very prevalent amongst the drug-dependent community, and the presence of nicotine and its metabolites in the basic extract can confuse the interpretation of the TLC plates. In System TA, nicotine and its metabolites coalesce with an Rf

Table 16. TLC data for some common narcotic drugs and metabolites

Compound	System	
	TA	TE
Norcodeine	13	—
Methadone metabolites	15	98
Nordihydrocodeine	16	25
Dihydrocodeine	26	36
Codeine	33	40
Morphine	37	20
Methadone	48	98
Quinine	51	36
Pethidine	52	80
Nicotine	54	70
Cotinine	60	40
Hydroxycotinine	60	20
Norcotinine	60	20
Cocaine	65	98
Dextropropoxyphene metabolites (streaking)	70	40

value of about 60. However, in System TE, three spots can be distinguished due to nicotine, cotinine, and norcotinine with hydroxy cotinine. The spots give grey-brown colours with acidified iodoplatinate solution, but in urine samples from heavy smokers, the colours are darker and can easily be mistaken for codeine (Rf 40) or morphine (Rf 20). The situation is resolved by the simultaneous viewing of both plates. To gain experience, urine samples from volunteers who smoke should be processed. Phenothiazines are sometimes administered by clinicians as part of the treatment of drug abuse. These produce so many urinary metabolites which react with acidified iodoplatinate solution that the detection of other drugs on the plate is made difficult, if not impossible. Detection of morphine in such samples is particularly difficult.

Cocaine

Cocaine gives a bright blue colour with acidified iodoplatinate solution, and has the same Rf value as methadone in System TE; the two are well separated in System TA. In practice, cocaine is rarely detected in urine samples by this technique. The drug is rapidly metabolised to benzoylecgonine, a polar substance which extracts poorly into organic solvents. Immunoassay kits which are highly specific for benzoylecgonine are available, and this method should be used if it is essential to detect cocaine abuse.

Codeine

It is essential to distinguish between codeine, a common constituent of cough medicines, and

morphine. A small amount of codeine is thought to be *O*-demethylated to morphine in man, but morphine is not detected by the above procedure, even when very large doses of codeine have been taken. A high intake of codeine can give rise to the detection of the *N*-demethylated metabolite, norcodeine. This appears on both thin-layer systems, and is likely to be confused with nordihydrocodeine.

Dextropropoxyphene

Dextropropoxyphene is extensively metabolised in the liver, and the parent drug is not detected in urine samples. The appearance of the metabolites is quite characteristic. In System TA they give a tailing blue spot at an Rf of about 70. In System TE they appear as a blue streak running from an Rf of about 40 down to the base-line.

Diamorphine

Diamorphine is rapidly de-acetylated to morphine in the body, and is not excreted in the urine. The detection of diamorphine is based, therefore, on the identification of morphine in urine (see below). If diamorphine is detected in an extract, this may indicate an attempt by the patient to deceive the analyst by the direct addition of the drug to the urine sample.

Dihydrocodeine

This drug gives two spots which have a distinctive appearance on the TLC plate. These spots are due to the drug itself and its metabolite, nordihydrocodeine, both of which react with acidified iodoplatinate solution to give deep brown-violet spots.

Methadone

Methadone is *N*-demethylated in the body to give a product which undergoes spontaneous cyclisation to yield two metabolites in the urine. In System TE, methadone and the metabolites run almost coincidentally on the solvent front, whereas in System TA, methadone runs just above morphine and is separated from the metabolites which run at about Rf 15. Both methadone and the metabolites give characteristic red-violet colours with acidified iodoplatinate solution. Methadone and the metabolites are usually found in most samples, but occasionally only the metabolites are detected.

Morphine

Morphine and codeine run together in System TA, but are well-separated in System TE; they appear as blue spots.

Morphine is excreted in the urine mainly as morphine-3-glucuronide, a water-soluble metabolite which is not extracted into organic solvents. Less than 10% of the drug is excreted as unchanged morphine. Thus, the sensitivity of the test for morphine can be considerably increased by hydrolysing the conjugated metabolites to yield free morphine. This can be achieved either by acid hydrolysis at a high temperature, or by incubating the urine sample with β -glucuronidase. The latter method is a more gentle procedure than acid hydrolysis which can destroy other drugs present in the sample. For routine work, all samples can be spiked with the enzyme solution when received, incubated overnight, and analysed on the following day.

The solutions produced after hydrolysis are examined by the methods for dependence-producing drugs described above under Extraction of Urine, and Thin-layer Chromatography.

ACID HYDROLYSIS

To 10 ml of urine in a screw-capped bottle (McCartney bottle) add 2 ml of *hydrochloric acid*, screw the cap on to the bottle and allow to stand in a boiling water-bath for 15 minutes. Cool the bottle, transfer the contents to a 250-ml beaker, add solid sodium bicarbonate to adjust the pH to 8.5 and, when the frothing has subsided, transfer the solution back into the McCartney bottle.

ENZYME HYDROLYSIS

Dissolve 5000 Fishman units of mixed glucuronidase/sulphatase (from *Helix pomatia*) in 1 ml of *acetate buffer* (pH 5). Adjust 10 ml of the urine to pH 5 with 0.1M hydrochloric acid, add 1 ml of the enzyme solution, and incubate at 37° for about 12 hours.

GAS CHROMATOGRAPHY OF DEPENDENCE-PRODUCING DRUGS

Spots of doubtful identity on the thin-layer chromatographic plates can sometimes be characterised by gas Chromatography on two independent columns using 2.5% SE-30 on Chromosorb G (System GA, p. 192), and 3% Poly A103 on Chromosorb W HP (System GF, p. 195).

Reference Solution. Prepare a solution in chloroform containing 10 μ g/ml of each of codeine, cyclizine, diphenhydramine, dipipanone, methadone, and pethidine.

Method. Inject 5 μ l of the reference solution on to both columns to ensure that the instruments are

functioning properly. The retention indices of these substances are listed in Table 17, together with those of other abused drugs.

To 0.5 ml of urine in a micro test-tube add 100 μ l of 2M sodium hydroxide, and 100 μ l of chloroform, mix for 30 seconds, centrifuge in a high-speed centrifuge for 2 minutes, and inject 3 to 5 μ l of the chloroform extract on to both columns. Identify any peaks which appear by reference to the retention data listed in Table 17. Further systems and data for the gas Chromatography of narcotic analgesics are given on p. 198.

Table 17. Retention indices for some commonly abused drugs and their metabolites

Compound	System	
	GA	GF
Norpethidine	1745	—
Pethidine	1751	1995
Glutethimide	1836	2315
Diphenhydramine	1873	2105
2-Ethyl-5-methyl-3,3-diphenyl-1-pyrroline (methadone metabolite)	1950	2190
Cyclizine	2020	2320
2-Ethyl-5-methyl-3,3-diphenylpyrrolidine (methadone metabolite)	2030	2280
Norethazine	2050	—
Methadone	2148	2370
Dextropropoxyphene	2188	2370
Pentazocine	2275	3030
Dihydrocodeine	2363	2840
Codeine	2376	2860
Dipipanone	2474	2710

Amphetamine and methylamphetamine are also frequently abused. Because of their volatility and the lack of specific detecting agents, gas Chromatography is the method of choice (see p. 17).

CANNABIS

The abuse of cannabis cannot be detected by thin-layer Chromatography or by conventional gas Chromatography because the concentrations of cannabinoids in urine are too low. Immunoassay, applied to either blood or urine, is the best method (see B. Law *et al.*, *J. analyt. Toxicol.*, 1984, 8, 14-18).

Cannabis and cannabis resin can be presumptively identified using the Duquenois Reagent (p. 133). Individual cannabinoids can be separated by thin-layer Chromatography (p. 172), gas Chromatography (p. 197), or high pressure liquid Chromatography (p. 217).

SCREENING FOR ABUSE OF SOLVENTS

The term 'glue-sniffing' derives from the abuse of adhesives which often contain solvents such as toluene, ethyl acetate, acetone, or ethyl methyl ketone. These, and similar compounds, also occur in a diverse range of other commercial products which may be abused, e.g. shoe-cleaners, nail varnish, dry-cleaning fluids, bottled fuel gases (butane and propane), aerosol propellents, and fire extinguishers (bromochlorodifluoromethane).

The gas chromatographic method given below uses head-space sampling and split flame ionisation: electron capture (9:1) detection. This increases the sensitivity towards halogenated solvents without unduly decreasing the flame ionisation detector response of non-electron-capturing species.

Collection and Storage of Samples. Blood samples should be taken as soon as solvent abuse is suspected because some inhaled compounds are excreted rapidly. Solvents can be identified in samples collected into plastic tubes which have been transported at ambient temperature and stored at 4°. However, for quantitative work, samples should be collected in stoppered glass bottles with a metal-faced wad (with 1% sodium fluoride added to inhibit esterase activity), refrigerated whilst being transported, and analysed immediately, especially when very volatile agents may be involved. Qualitative assay of volatile substances such as dichloro-difluoromethane, propane, butane, and isobutane is still possible in blood specimens stored at — 20° for 3 months.

Blood specimens should be packaged separately from any material thought to have been abused in order to avoid contamination. Pressure-sensitive adhesive tapes which contain solvents such as toluene should not be used to seal the sample containers.

Gas Chromatography of Solvents

The column used is 0.3% Carbowax 20M on Carbpak C. This is System GI (p. 199), and reference should be made to this system for full details of operating conditions and retention data.

Reference Mixture. This is prepared in three stages.

1. Prepare a mixture of the substances listed below. This mixture should be stored in a glass-stoppered bottle at -20°.

2. Introduce the following volumes of the three gaseous compounds into an evacuated gas-sampling

Acetone	20ml	Isopropyl alcohol	20ml
Carbon tetrachloride	200µl	Isopropyl nitrate	1ml
Chlorbutol	10 mg	Methanol	15 ml
Chloroform	1 5ml	Tetrachloroethylene	100 µl
Ethanol	20ml	Toluene	50ml
Ethyl acetate	20ml	1,1,1 -Trichloroethane	1ml
Ethyl methyl ketone	20ml	1,1,2-Trichloroethane	2ml
Ethylbenzene	10ml	Trichloroethanol	50 µl
Hexane	40ml	Trichloroethylene	1ml
Isobutyl methyl ketone	5ml		

bulb: bromochlorodifluoromethane 20 µl, dichlorodifluoromethane 750 µl, and trichlorofluoromethane 20 µl.

3. Admit air to the gas-sampling bulb to atmospheric pressure and introduce 25 µl of the liquid mixture prepared above.

Inject aliquots from 0.01 to 1.0 µl of this reference mixture on to the column to produce the standard chromatogram.

Internal Standard Solution. Prepare two stock solutions containing, respectively, 50 mg of 1,1,2-trichloroethane and 50 mg of ethylbenzene, each in 50 ml of whole blood. The purity of these substances should be checked by gas chromatography, particularly for the presence of 1,1,1-trichloroethane and toluene.

Dilute 1 ml of the trichloroethane solution and 2.5 ml of the ethylbenzene solution to 100 ml with glass-distilled water containing 100 mg of sodium azide. This working internal standard solution can be stored in 1-ml portions at - 20°.

Method. Using a 1-ml disposable plastic syringe, transfer 100 µl of the internal standard solution to a 7-ml nitrogen-filled vial sealed with a crimped-on PTFE-silicone disk, and maintain the vial at 65° in a heating block for 15 minutes. Remove 400 µl of the head-space in the vial with a warmed (40°) gas-tight glass syringe, and inject on to the chromatographic column to check for any extraneous peaks contributed by the vial, cap, syringe, or laboratory environment.

Add to the vial 200 µl of the sample (whole blood, plasma, or serum), using a disposable syringe, heat at 65° for a further 15 minutes, and inject 400 µl of the head-space on to the column.

Disks faced with PTFE should be used in the head-space vials as some solvents may be absorbed by butyl-rubber caps. Contamination of samples with chloroform, usually from the laboratory environment, is common. An artefact eluting with a retention time of 33.2 minutes derives from the gas-chromatograph septa.

After sample injection, the gas-tight syringe should be purged by removing the plunger and drawing ambient air through the barrel and needle using a vacuum pump.

SCREENING FOR ABUSE OF DIURETICS

Benzothiadiazine diuretics (thiazides) may be abused by patients who are obsessed with losing weight; prolonged use can cause severe hypokalaemia and hypomagnesaemia.

Diuretics can be detected by high pressure liquid chromatography using System HN (p. 217).

Detection of Diuretics in Urine by Thin-layer Chromatography

Reference Solutions. Prepare reference solutions containing 1 mg/ml of each of the substances listed in Table 18, using ethyl acetate as solvent.

Table 18. TLC data for some common diuretics

Compound	System TF Rf	Colour after diazotisation
Frusemide	12	red
Chlorothiazide	16	pink
Hydrochlorothiazide	39	pink
Hydroflumethiazide	47	orange
Cyclophenethiazide	62	pink
Bendroflumazide	71	orange

Method. To 10 ml of urine add 1 ml of M hydrochloric acid and 10 ml of ethyl acetate, mix on a rotary mixer for 10 minutes, and centrifuge. Transfer the ethyl acetate layer to a second tube, add 10 ml of a 5% solution of lead acetate, stopper the tube, and mix gently for 1 to 2 minutes (washing with lead acetate solution removes urinary pigments from the extract). Centrifuge, transfer the solvent extract to a 15-ml conical test-tube, and evaporate to dryness under a stream of air or nitrogen. The extract is examined using silica gel G plates and ethyl acetate as the mobile phase (System TF, p. 168). Score the plates vertically to bring about an even movement of the mobile phase, and score a horizontal line 10 cm from the bottom of the plate to mark the distance travelled by the solvent front. Dissolve the residue from the extract in 100 µl of acetone and immediately apply 30 µl to the plate; at the same time apply 10-µl portions of each reference solution. After development, dry the plate with a hot-air blower.

Location Reagents. Spray the plate with hydrochloric acid and heat in an oven at 100° for 10 minutes in order to hydrolyse any thiazide present

to the corresponding sulphonamide derivative. Then spray the plate with the following reagents in the sequence shown, drying the plate under warm air after each application.

1. 9M sulphuric acid (spray lightly)
 2. A freshly-prepared 1% solution of sodium nitrite
 3. A 5% solution of ammonium sulphamate
 4. *N*-(1-naphthyl)ethylenediamine solution
- Further data on the thin-layer chromatography of diuretics is given on p. 172.

INTERFERING SUBSTANCES

Interference may arise from the presence of benzodiazepines; these are hydrolysed to amino-benzophenones which also undergo diazotisation. Sulphonamides are also detected by this procedure, and can be distinguished by either of two methods. The unhydrolysed plate may be sprayed with *Van Urk reagent*, then heated at 100° for 5 minutes. This gives yellow colours with sulphonamides but not with thiazides. Alternatively, hydrolysed extracts of urine and of reference solutions can be chromatographed by the following procedure.

Reference Solution. Prepare a solution containing 10 µg/ml of bendroflumazide, chlorothiazide, and frusemide in normal urine.

Method. Extract 10 ml of the reference solution and 10 ml of the urine sample by the method given above. To each dried extract add 1 ml of 10M sodium hydroxide, heat in an autoclave for 15 minutes at 121°, cool, acidify the solutions, extract each with 10 ml of ethyl acetate, and evaporate the extracts to dryness. Dissolve the residues in 100 µl of acetone and chromatograph 30 µl of each as described above.

Table 19. TLC data for the hydrolysis products of some common diuretics

Parent drug	Hydrolysis product	System TF Rf	Colour after diazotisation
Frusemide	2-amino-4-chlorobenzoic acid-5-sulphonamide	17	red
Chlorothiazide Cyclophenethiazide Hydrochlorothiazide	4-amino-6-chlorobenzen-1,3-disulphonamide	48	pink
Bendroflumazide Hydroflumethiazide	4-amino-6-trifluoromethylbenzen-1,3-disulphonamide	61	orange

SCREENING FOR ABUSE OF LAXATIVES

Colonic stimulants are the most commonly misused laxative preparations. These include bisacodyl, danthron, oxyphenisatin, and phenolphthalein. Some vegetable laxatives, for example aloes, cas-

cara and senna, give rise to the anthraquinone derivative rhein (1,8-dihydroxyanthraquinone-3-carboxylic acid).

A 50-ml sample of urine should be collected on three successive days in order to improve the chances of catching a laxative abuser. The colour of the urine should be noted; heavy use of danthron colours the urine pink or blue. If the urine turns red when made alkaline, this may indicate the presence of phenolphthalein or a vegetable laxative.

Detection of Laxatives in Urine by Thin-layer Chromatography

F. A. de Wolif *et al.*, *Clin. Chem.*, 1981, 27, 914-917.

Laxatives can be detected in urine by this method for at least 18 hours after ingestion.

Reference Solutions. 1. Dissolve 2 mg of phenolphthalein in 1 ml of ethanol and dilute to 10 ml with chloroform.

2. Dissolve 2 mg of danthron in 10 ml of chloroform.

3. Dissolve 2 mg of rhein in 10 ml of chloroform.

(A method for preparing rhein from sennoside A or B has been described by J. Lemli, *J. Pharm. Pharmac.*, 1965, 77, 227-232.)

4. Bisacodyl and oxyphenisatin are substantially metabolised in the liver by a hydrolytic process, and far more of the hydrolysis product is excreted in the urine than unchanged drug. Hence, the reference solutions contain both the parent drug and the hydrolysis product, and are prepared in the following manner. Dissolve 2 mg of each substance in 2 ml of ethanol, add 20 μ l of 6M sodium hydroxide, heat for 30 minutes at 70°, cool, neutralise with 20 μ l of 6M hydrochloric acid, and add 8 ml of chloroform and 2 mg of the parent substance to each corresponding solution. (The precipitate of sodium chloride which forms on neutralisation does not interfere with the chromatography.)

Method. Enzymatic hydrolysis of the glucuronide metabolites is essential before extraction.

Adjust 20 ml of urine to pH 5 with 0.1 M hydrochloric acid, add 2 ml of *acetate buffer* (pH 5), and 10 000 Fishman units of mixed glucuronidase/ sulphatase (from *Helix pomatid*), and heat in a water-bath at 60° for 2 hours. Pour the urine on to an unbuffered Tox Elut column (see Reagent Appendix) and leave for 2 to 3 minutes to allow the sample to soak into the column. Place a 50-ml test-tube under the column outlet and pour on to the column 20 ml of a mixture of chloroform: isopropyl alcohol (9:1). When the elution is complete, insert into the top of the column a hollow rubber stopper

connected by a rubber tube to a pressure bulb, and apply gentle pressure to discharge residual solvent. Place the tube containing the eluate in a beaker of hot water and evaporate the extract to dryness under a stream of nitrogen. Dissolve the residue in 100 μ l of chloroform just prior to examination by the following thin-layer chromatography systems.

System 1

PLATES. High performance silica gel (10 x 20 cm) with fluorescent indicator and concentration zone (see Reagent Appendix).

MOBILE PHASE. *m*-Xylene: isobutyl methyl ketone: methanol (10:10:1).

System 2

PLATES. As used for System 1.

MOBILE PHASE. Hexane: toluene: *acetic acid* (3:1:1).

Score two plates vertically to divide them into two (10x10 cm) zones, and score a horizontal line parallel to the concentration zone at a distance of 5 cm.

To one plate apply 5-ml aliquots of the reference solutions of bisacodyl, danthron, oxyphenisatin, and phenolphthalein to each zone, together with a 3-ml and a 10-ml aliquot of the urine extract, also to each zone. Develop the plate using System 1. To the second plate apply 5-ml aliquots of the reference solutions of danthron, phenolphthalein, and rhein to each zone, together with a 3-ml and a 10-ml aliquot of the urine extract. Develop this plate using System 2.

Remove the plates and dry under a hot-air blower. **Location Reagents.** Danthron is visible as a yellow spot on the first plate, or as an orange spot on the second plate. Examine the plates under ultraviolet light at 254 nm and 366 nm. All the substances absorb at 254 nm; danthron and rhein give an orange fluorescence at 366 nm.

Spray the left-hand side of each plate with 6M sodium hydroxide. Bisacodyl and its hydrolysis products give violet spots; oxyphenisatin appears as three faint pink spots; phenolphthalein and rhein give a violet and a red spot, respectively. Spray the left-hand side of the first plate with a freshly prepared 1% solution of potassium ferri-cyanide.

Heat both plates to 100° and spray the right-hand side immediately with *Mandolin's reagent*.

The R_f values and colour reactions of these compounds and their hydrolysis products are listed in Table 20.

Compound	System 1 Rf relative to phenolphthalein	System 2 Rf relative to rhein	Visible colour	Colour after spraying with sodium hydroxide	Colour after spraying with Mandolin's reagent
Bisacodyl	98	—	—	violet	violet
hydrolysis product	71	—	—	violet	violet
Danthron	138	138	orange	red	brown
Oxyphenisatin	98	—	—	pink*	pink
hydrolysis product 1	80	—	—	pink*	pink
hydrolysis product 2	63	—	—	pink*	pink
Phenolphthalein	100	8	—	violet	brown
Rhein	—	100	yellow	red	green-yellow

* Violet after spraying with potassium ferricyanide

Forensic Toxicology

J.V. Jackson

The first complete work of international importance on the subject of forensic toxicology was written by Orfila in 1813 (*Traite des poisons tires des regnes mineral vegetal et animal, ou toxicologie generale, consideree sous les rapports de la pathologie et de medecine legale*). It was an immediate success and won him the title of 'Father of Toxicology'. "The chemist", said Orfila, "horried by the crime of homicidal poisoning, must aim to perfect the process necessary for establishing the case of poisoning in order to reveal the crime and to assist the magistrate punish the guilty". It is interesting to note that he realised the necessity of adequate proof of identification, emphasised the importance of what we now call quality assurance (purity of standards etc.), and anticipated the need for pharmaceutical, clinical, industrial, and environmental toxicology. The term 'forensic toxicology' covers any application of the science and study of poisons to the elucidation of questions that occur in judicial proceedings. The subject is usually associated with work for the police, the coroner, and the criminal law courts. However, the analysis and identification of controlled drugs and the maintenance of agricultural, industrial, and public health legislation (to ensure clean air, pure water, and safe food supplies) are all aspects of forensic toxicology. Like the forensic toxicologist, analysts employed in these areas may at times find their work the subject of severe public scrutiny in a law court, and both groups should be aware of the strengths and limitations of each other's methodology.

Accidental self-poisoning and attempted suicide cases are generally the responsibility of the clinical toxicologist or the hospital biochemist, working in conjunction with a poison control centre. A small proportion of these cases is referred to the forensic toxicologist, either because of an allegation of malicious poisoning, or because the patient dies and a coroner's inquest is ordered. The preliminary analysis may already have been carried out, and close co-operation between the forensic and hospital laboratories is obviously desirable. What follows is an attempt to provide an account of the principles,

methodology, and special problems encountered in forensic toxicology for all workers in these related fields, and for chemists and pharmacists in more remote areas of the world who may be faced with the request 'test for poisons'.

PRINCIPLES OF FORENSIC TOXICOLOGY

The forensic toxicologist is expected to detect and identify poisons, but if we define 'poison' as a chemical substance harmful to living organisms, it is obvious that 'harmfulness' is not a property that can be measured by any chemical method of analysis. Toxicity is a biological concept, usually determined by some form of bioassay. Although a bioassay may be used to detect the presence of a poison it does not provide the specific identification which is a prime requirement for forensic work. Prosecutions based almost entirely on animal experiments have succeeded in the past (for instance the trial of Dr. Pommerais, Paris, 1862, was the first successful detection of digitalis poisoning), but this method alone would not be considered adequate in a modern trial. However, bioassays are probably the most rapid way of detecting poisoned food. For example, contaminated flour was implicated as the cause of a large outbreak of poisoning in the Middle East by feeding pigeons with samples of the food eaten by the victims. Subsequent chemical analysis of the flour identified the contaminant as endrin. Chemical analysis of all the various food samples would have taken weeks.

If official regulations permit this method to be used, it can be useful provided that the analyst is aware of the problem of species differences which can lead to erroneous conclusions. If the animal is more sensitive to the toxin than man (e.g. benzoic acid in the cat), a false positive result would be obtained. Alternatively, a false negative result would be obtained if the animal were more resistant (e.g. *Amanita phalloides* and the rabbit). This aspect is illustrated by TCDD (2,3,7,8-tetrachlorodibenzo-*p*-dioxin), the extremely persistent impurity, present in the systemic herbicide trichlorophenoxy-acetic acid, which was released in the Seveso

disaster in 1976. Species differences for the LD50 (mg/kg) of this substance have been reported to be: guinea pig 0.0006, mouse 0.001, rat 0.04, and dog 0.1.

This apparently simple and logical method of testing for the presence of a poison has its limitations as far as the forensic toxicologist is concerned, and the bulk of all forensic analyses must be submitted to the chemist. However, all the techniques of analytical chemistry, from colour tests to mass spectrometry, are based on the molecular structure of the compounds involved, whereas toxicity is related to the dose. Anything can become a poison if it exceeds the threshold limit of the organism's ability to deal with it. Without a living organism as a test reagent, the word 'poison' is an abstract concept.

If the poison is not specified by name, the request to 'test for poisons' is a major problem for the chemist, because there is no single chemical method of analysis capable of detecting all the various poisons. At least seven different analytical schemes are required to exclude even the most commonly encountered poisons (Fig. 1). Compared with toxicologists in academic research or industry, the task of the forensic toxicologist is made more difficult because the analytical material, the available time, and the resources are all severely limited. He has scarcely any control over the sampling time or the selection of material for analysis, and no certain knowledge that a poison is present.

Forensic toxicology demands an overall analytical system designed to exclude or indicate the presence of any poison in each of the chemical groups shown in Fig. 1. Most of the numerous screening procedures reported in the literature are too limited to permit a confident negative report. All too often they are drug oriented, despite the fact that two-thirds of all discovered criminal poisonings are due to compounds other than drugs.

Apart from these analytical problems, the legal aspect of the work demands a scrupulous attention to details which are of little or no importance in other types of toxicology. Failure to make full descriptive notes on the items received, a simple error in the date the analysis was performed, or neglecting to check reagent purity, can become evidence of careless work in the hands of an astute lawyer. He may, with justification, explore the extent of the toxicologist's experience and knowledge, demand a detailed account of the analytical methods, and challenge the integrity of any opinion.

The crucial evidence of identification and quantification of the poison may be faultless and the conclusions correct but, if the court's confidence in the forensic toxicologist as an unbiased scientific expert is destroyed, the case may be lost. Orfila was well acquainted with this aspect of forensic toxicology, and the guiding principles he established over 100 years ago are still applicable. These may be summarised as follows:

All chemists undertaking this work must have toxicological experience.

The analyst must be given a complete case history containing all the information available.

All the evidential material, suitably labelled and sealed in clean containers, must be submitted and examined.

All the known identification tests should be applied, and adequate notes made at the time.

All the necessary reagents used for these tests should be pure, and blank tests should be performed to establish this fact.

All tests should be repeated, and compared with control samples to which the indicated poison has been added.

Strict adherence to these principles makes forensic toxicology one of the slowest and most expensive forms of analysis. However, this must be accepted not only to ensure justice for the poisoned victim and for the accused, but also to protect the integrity and reputation of the analyst and the laboratory he represents.

RANGE OF CASES SUBMITTED

The ultimate objective of any forensic scientist is to attempt to provide answers to questions that may arise during criminal investigations or in subsequent court proceedings. The traditional question which must be answered is 'Has this person been poisoned?', together with the supplementary queries that follow if the result is positive such as 'What was the nature of the poison?', 'How was it administered?', and 'Was it a dangerous or lethal amount?'.

Laws governing the possession and use of narcotic and stimulant drugs, and legislation concerned with the influence of drink or drugs on driving skills, have increased the work-load of many forensic laboratories; these cases can account for over 70% of the total submitted.

Modern analytical methods can give the forensic toxicologist the ability to answer questions which previously were considered either hopeless or not

worth considering because the results were so often negative. For example, in the 1960's over 90% of all allegedly poisoned food and drink samples submitted for analysis to the Metropolitan Police Forensic Science Laboratory were negative. Today, over 60% are positive. Methods which are sensitive to 1 µg or less of an increasing number of drugs and poisons make it worthwhile to undertake an analysis, even when the plate, cup, or container has apparently no food or drink left in it.

Drugs may be detected in blood at therapeutic concentrations, and it is possible, therefore, to obtain clues to the clinical history of the deceased, the victim, or the accused, even when they are unable or unwilling to provide this information for themselves. Thus, the discovery of drugs used in the treatment of epilepsy, diabetes, etc., in a blood sample taken from an unidentified body, may start a new train of inquiries leading to successful identification of the body. Similarly, allegations of doping prior to rape or robbery may be refuted or confirmed.

The final example of what might be termed the 'new forensic toxicology' concerns the analytical checking of statements made by witnesses during the course of a police inquiry. Provided that a blood or urine sample is taken within about 12 hours of an event, there is a good chance of checking the truth of statements such as 'I don't remember what happened because I was high on drugs at the time', 'I used to be an addict, but I haven't taken anything for over a year', or 'I killed him in self-defence because after taking LSD he went berserk and attacked me with a knife'.

Stains can also be examined for drugs and poisons. For example, if the victim notices a nasty taste and spits out the drink, the allegation that someone tried to poison him can be investigated if the stained garment is submitted for analysis. Certain drugs can be detected in blood stains, and this has proved to be useful evidence additional to examination for the blood group, especially when the blood group is common. The request 'test for drugs' is almost as much a routine request by the detective investigating a murder as the request for serology. In most cases, the results obtained in the various types of cases mentioned above can be proved conclusively, i.e. the identity of the poison can be confirmed by more than one method, and it can be quantified. Even when specific identification is not feasible, an opinion as to whether the suspect is most probably telling the truth or is lying, can be of value to the investigator.

ANALYTICAL REQUIREMENTS

It is impossible to design a single analytical scheme which is both capable of detecting all the drugs and poisons now available and suitable for all the various purposes mentioned above. The forensic toxicologist needs a repertoire of standard methods which he can modify according to the nature of the investigation, the type and amount of material for analysis, and the time and resources he has available. This collection of standard methods should include about a dozen general screening methods and as many special methods as he can acquire and practise.

General screening methods are designed to detect, or exclude, the majority of poisons in a particular group in a single series of operations. Because the main objective is detection rather than quantification, general screening methods are usually more flexible than special methods and can therefore be applied to a wide variety of materials. They are essential for the investigation of unknown poisonings, and have some advantages even when the toxic agent is known or suspected. A good general method will provide a provisional identification which can then be confirmed by the application of a quantitative special method.

Special methods will only detect, or exclude, a limited number of related chemical compounds. Because of their more limited purpose they can be made more efficient, rapid, and selective than general methods but in certain circumstances they waste both time and material. The temptation to screen for poisons by employing a whole series of special methods should be resisted. Some of the specialised methods designed to detect a particular poison or a chemically-related group of drugs (e.g. barbiturates, phenothiazines) are not as selective as they purport to be. This is because the extraction procedures have been simplified for rapid processing, because they utilise a non-specific identification technique, or, more frequently, because they are designed to quantify the drug rather than identify it. For example, many methods based on a colour reaction only require the preparation of a protein-free filtrate; consequently, the drug or poison is never really separated from most of the endogenous material and the only evidence of identification involves the dangerous assumption that the positive response is due to the compound sought. If possible, non-selective special methods should be avoided in forensic toxicology. Unfortunately they are often the only type the manufacturer of the compound can supply.

Classification of Poisons

Drugs and poisons can be classified alphabetically, pharmacologically (antidiabetic, anticonvulsant, etc.), or by chemical structure (barbiturates, phenothiazines, etc.). However, for analytical purposes it is more useful to classify poisons according to the method used for extraction. Five major groups are usually considered:

- (a) gaseous and volatile substances isolated by diffusion or distillation;
- (b) organic non-volatile substances isolated by solvent extraction;
- (c) metallic poisons isolated by ashing or by wet oxidation of the organic matter;
- (d) toxic anions isolated by dialysis; and
- (e) miscellaneous poisons which require special extraction techniques such as ion-exchange columns, formation of derivatives or ion-pairs, freeze-drying and continuous extraction with a polar solvent.

Some of these groups have been sub-divided because they are too large or because alternative methods of extraction are available. The seven groups so formed are illustrated in Fig. 1.

Fig. 1. The seven major groups of poisons.

Most analyses require several unit operations, namely separation of the poison from the biological material, isolation and purification of the toxic substance and its metabolites, identification, confirmation of identity, and quantification. The most useful methods are those which combine two or more of these unit

operations. Thus, colour tests which can be applied to the sample directly without the need for any isolation or purification processes are indispensable in the initial stages of an analysis. Immunoassay techniques also eliminate the need for many separate operations and, like colour tests, can provide a tentative identification and approximate quantification of the poison. However, a disadvantage of both these methods is that a negative result eliminates only a few of the possible toxic substances. Consequently, additional colour tests or immunoassays are required before that particular group of poisons can be excluded. This type of sequential testing can waste much time.

A broad-spectrum screen, capable of detecting or eliminating most of the poisons in a group, usually requires a combination of three or more of the available techniques. For the drug and pesticide groups, the only combination potentially capable of encompassing all the required steps is mass spectrometry coupled with either gas chromatography or high pressure liquid chromatography. However, a simple, direct solvent extraction scheme is generally employed to eliminate endogenous substances which might otherwise reduce the efficiency of the system.

Case Investigation

Analyses may be required to answer specific questions concerning, for instance, the amount of alcohol in blood. Alternatively, the enquiry may be more general, such as 'Was this food poisoned?'. This latter type of case is termed a 'general unknown' (that is, those cases where the analyst knows nothing about the nature of the poison, if any). All 7 groups of poisons shown in Fig. 1 should be excluded before a negative report can be given. Fortunately, group tests are available for four of these groups, i.e. volatile compounds, drugs, metals, and pesticides. Specific tests must be used to detect gases, anions, and miscellaneous compounds. Obviously, the choice of which group should be eliminated first is critical if a rapid answer is expected.

Intuitive considerations or 'guesswork' nearly always predominate in a 'general unknown' case. It is common to commence with a drug screen, and this is usually confined to those drugs which are soluble. If the case is a suicide attempt or a suspect doping, the choice is justified but, if all the circumstances have not been reported to the analyst, it may not be right to make the assumption that a drug is present.

Most poisoning cases involve alcohol, carbon monoxide, hypnotics, narcotics, sedatives, or tranquillisers. However, it may be that these are the most common poisons because they are sought more often than other toxic substances, and because they are almost the only poisons for which comprehensive screening systems have been published. There are inherent dangers in this pragmatic approach because there is no differentiation between self-poisonings and criminal poisonings. On the other hand, a completely systematic and comprehensive analytical scheme covering all the poison groups is extremely costly.

The first essential task of the analyst must be to ensure that the so-called 'general unknown' case is an authentic unknown poisoning. Only about 10% of submitted cases do not have any guiding features, and these cases consist mainly of unidentified drowned, burnt, or decomposed bodies, or of the submission of some untasted, but allegedly poisoned, food sample. In most cases there are nearly always some facts available which can provide clues to the most likely group of poisons to be excluded as a first action. Thus, if the time of onset of the symptoms was less than 1 hour, and there is no evidence of injected material, then the sample should be examined for gases and volatile poisons before other groups. Severe vomiting and diarrhoea provide an indication of possible metal poisoning.

The age and occupation of the victim or the site of the incident may guide the choice of the first group screen to be employed. For instance, few elderly people indulge in solvent sniffing, farm workers have easier access to the more toxic pesticides, and a death in an electroplating factory would certainly require cyanide to be eliminated. These facts are not freely given but must be sought.

If no circumstantial details are provided the most useful preliminary analytical instrument is the telephone! The prerequisite for a case to be accepted into a forensic toxicology department is suspicion. Details of the circumstances leading to the conclusion that a criminal action has taken place must be supplied to the analyst in order for him to plan his analysis.

Every case submitted must be accompanied by a form similar to that shown below and every effort must be made to obtain the information requested on the form. If possible, a personal consultation with the investigating officer should also be arranged.

Information to be submitted with the exhibits in all cases where there is suspicion of poisoning or doping

Name of victim Sex
Age Weight or height
Nationality Recent foreign travel?
Occupation (give details of end-product of factory or firm).

Medical History

Did victim suffer from viral hepatitis or any other infectious disease?

Any recent illness or chronic disease? What drugs were prescribed?

Was victim an alcoholic, drug addict, smoker?

What poison is suspected? How much?

(Tablet bottles, syringes etc., found near body should be submitted.)

Give names of any drugs or poisons to which victim or associates had access (apart from any mentioned above).

Times

Date and time victim last seen to have been in normal health.

Date and time of illness or death, and where found, e.g. at work, in bed, outdoors etc.

If these times are not known, when was the victim found? Time and

details of last meal.

Treatment

Any medical attention given after the suspected poisoning or doping?

Time of hospital admission. Date and time discharged.

Details of any treatment given (volume of stomach wash, time when blood/urine samples taken).

Hospital analysis: supplied/not done/not available

Tick any of the following symptoms that apply:

Diarrhoea, vomiting, thirst, blindness, constipation, cyanosis (blue tinge to skin), jaundice, loss of weight, shivering, convulsions, eye pupils dilated, eye pupils constricted, delirium, coma, sweating, renal failure.

Name of pathologist or doctor. Autopsy report sent Yes/No

Date of autopsy and possible cause of death.

Any further information which could be useful to the laboratory, e.g. victim pregnant, details of suspect (especially occupation and end-product of factory or firm, comments made by victim, witnesses or suspect).

Samples Required

If victim alive: vomit, stomach aspirate or wash, blood and urine.

If victim dead:

Stomach contents	All available (no preservative); enquire if stomach wash or vomit is available. If no contents, submit stomach.
Blood	
Femoral vein	30 ml unpreserved and 5 ml preserved (for alcohol analysis). Identify source. Do not mix.
Heart	All available from intact heart chambers. Avoid body cavity samples. Enquire if antemortem samples are available.
Urine	All available, however small a volume (preserved). Enquire if antemortem samples are available. If no urine, submit kidney and bile.
Liver	250 g. Gall bladder should not be included with this sample.

If the suspected poison is a volatile substance, brain and lungs will be required. Bone and hair are needed if metal poisoning is suspected. Brain should always be submitted if the body is decomposed. If in doubt, consult the laboratory.

Glass jars should be used whenever possible. Samples should be properly labelled and sealed. The label should include the name of the victim, signature of pathologist, and the date. Antemortem samples should also specify time of sampling.

Although investigation should always precede analysis, there is no need to wait for full completion of the questionnaire because some poisons are so common that they should always be eliminated. These include ethanol, aspirin, paracetamol, barbiturates, and carbon monoxide. Many of these can be checked by rapid analytical probing tests before a full group screen is applied. Completion of the following analytical probing tests will, in many cases, provide clues to the nature of the poison.

Analytical Probing**MEDICAMENTS NEAR THE BODY**

It is a common mistake to spend too much time identifying every tablet or capsule found at the scene (in many cases they have nothing to do with the event). However, it is equally foolish not to have a quick attempt at identification before analysing body fluids (see p. 50).

FOOD OR DRINK RESIDUES NEAR THE BODY

The priority given to this aspect will depend on the case history, but a rapid initial examination at an early stage is often useful (see p. 48).

BODY FLUIDS

A number of preliminary tests should be carried out

in order to confirm or exclude the most common toxic agents.

Urine

The following tests, details of which are given on p. 4, should be performed: Trinder's test for salicylates, cresol-ammonia test for paracetamol, FPN reagent for phenothiazines, Fujiwara test for trichloro-compounds, and the dithionite test for paraquat and diquat. In addition, the content of alcohol should be determined by gas chromatography (p. 19).

Stomach Contents

This sample should be examined visually for colour and the presence of tablet residues or excipients (often maize starch). The odour should be noted as this may indicate the presence of alcohols, aldehydes, ketones, phenols, cyanide, ethchlorvynol, nicotine, etc. The following tests, details of which are given on p. 5, should be performed: Trinder's test for salicylates, cresol-ammonia test for paracetamol, FPN reagent for phenothiazines, Fujiwara test for trichloro-compounds, and the diphenyl-amine test for oxidising agents. In addition, the Reinsch Test for heavy metals (p. 57) should be carried out, and a diluted, filtered extract examined by direct ultraviolet spectrophotometry for drugs with high A values.

Blood

Tests on this sample should include a quantification of alcohol by gas chromatography (p. 19), and detection and quantification of carbon monoxide by spectrophotometry (p. 20).

The precise order in which these tests are carried out will depend on the information available, but most of them will need to be done at some time, unless the evidence overwhelmingly indicates a specific poison (e.g. cyanide). Even in these cases, ancillary questions may arise in court, for instance, was the victim doped or drunk prior to the administration of the fatal poison? A careful toxicologist should, therefore, carry out most of the above plus a routine drug screen in every case. For example, not all carbon monoxide cases are suicidal or accidental, even if the circumstantial evidence seems to indicate a non-criminal cause of death.

The flow chart (Fig. 2) shows how the information obtained from the questionnaire and the suggested analytical probing are combined to obtain a probable identity, or at least the type of poison involved.

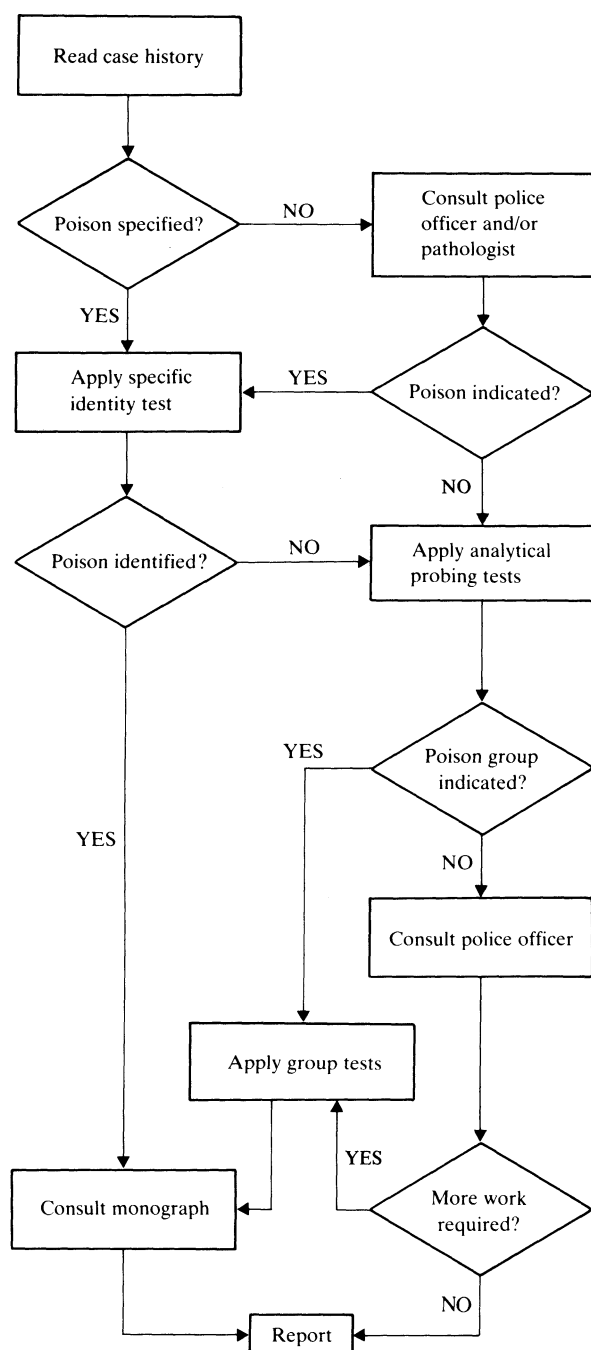

Fig. 2. Analytical probing flow chart.

If the analytical probing suggested above is compared with the poison group classification shown in Fig. 1, it can be seen that every group has been checked by at least one test designed to confirm or exclude one or more of the most common toxic agents within that classification, with the exception of Group 7, Miscellaneous Poisons. The most common poisons in Group 7 are cannabinoids, digoxin, and insulin.

If the laboratory has facilities for immunoassay, tests for this most difficult group can be started. Radioimmunoassays are essential for traffic-offence cases (drug-driving cases), and can assist greatly in the probing phase of an investigation. Immunoassays are not specific, and advantage can be taken of this cross-reactivity to provide general tests for barbiturates, benzodiazepines, tricyclic antidepressants, and opiates.

A simple drug screen of the urine and stomach contents, such as Scheme 1 (p. 4), may be undertaken as part of this probing phase, but it is better to carry out a more traditional multi-fractional screen (Scheme 2, p. 10) rather than risk the need to repeat this part of the analysis when nothing has been detected by the simple screen. Both approaches are valid depending on the type of case predominating in the laboratory. If most of the work is undertaken for the coroner and pathologist and concerns mainly the investigation of suspected suicidal overdoses, then the simple drug screen is probably better. However, if there is a large number of antemortem investigations (i.e. non-fatal doping, poisoning, traffic and drug offences), then the traditional multi-fraction screen is more economical of both sample and time, in the long-term. Moreover, there is an increasing demand for the forensic laboratory to investigate the possibility of drug involvement in murder and manslaughter cases. In these cases, proof is required of drug ingestion rather than of the consumption of an overdose, so that a simple drug screen might not suffice.

Only a small number of qualitative tests utilise the blood sample. This is because it is generally the most limited sample, and is also the most valuable for the confirmation and quantification phases of a toxicological analysis.

The analysis of tissue samples was formerly a prerequisite of any toxicological examination, but it is less important now provided that the laboratory has sensitive, instrumental methods in routine use. However, analysis of the liver is essential when a full range of body fluids cannot be obtained, or if the detailed analysis of these fluids fails to provide an answer. For these reasons, liver should still be requested as a routine specimen in every postmortem case. It is doubtful if the supply and analysis of a full set of body organs, advocated by many classical toxicology textbooks, can now be justified for there is little evidence that such routines have uncovered homicidal poisonings that would otherwise have been overlooked. In general, the analysis of liver

specimens need only be considered in those cases where the circumstantial evidence conflicts strongly with the analytical results.

Toxic blood concentrations of some drugs (e.g. thioridazine) are not significantly higher than therapeutic concentrations. This is not generally true of liver concentrations which, in postmortem specimens, may be over ten times higher than those obtained from patients on therapeutic dose regimens. Liver analysis in these cases will provide a more certain indication of a fatal overdose.

Tissue analysis is obviously a necessity for exhumed or decomposed bodies or when the victim has survived for several days following ingestion of the poison. In all these cases the routine samples (stomach contents, blood, and urine) may not be available or if available may not produce meaningful results.

GROUP TESTS

In the following pages, each classified group of poisons is discussed in turn. The group tables summarise the type of circumstantial evidence usually characteristic for the majority of poisons, list possible spot or probing tests to confirm or refute the circumstantial indications, and indicate analytical methods required for the group. A general method is suggested where this is available. The figure given under 'number of compounds reported' is the number of compounds in the group that has been reported to the International Association of Forensic Toxicologists as being involved in poisoning cases over a fifteen-year period. The figure given under 'number of compounds to be excluded' is a very rough estimate of the total number of poisons within that particular group.

Group 1 Poisons: Gases

The presence of this group of poisons is usually indicated by the circumstances of the incident (providing they have been reported in full to the analyst). Furthermore, the identity of the actual gas involved is often indicated by the circumstantial evidence. This is fortunate since no single-stage group test or analytical method is available for this group (Table 1). However, a few points need careful investigation. For instance, a portable heater may have been removed from the room where the death occurred. In one case, a devoted mother warmed her son's cold bedroom before he was awake using a defective paraffin heater, which was subsequently transferred to warm the bathroom before he took a bath. He was found dead in bed with no visible source of carbon monoxide in the room and so the laboratory

was only requested to analyse for drugs. (The classic pink skin colour due to carboxy-haemoglobin is not always apparent!) Fortunately, a routine test for carbon monoxide established the cause of death before too much time had been wasted looking for drugs. The analyst should also enquire whether oxygen was administered or artificial respiration was attempted before death. Carboxyhaemoglobin at a non-fatal concentration may be found in a postmortem blood sample, but no one may think to inform the analyst of the first-aid which has been given.

Table 1. Group 1 Poisons: Gases

<i>Indications</i>	
Symptoms	Apnoea, asphyxia, dyspnoea, vomiting, pink or red skin colour
Onset of symptoms	Very rapid onset of illness or death
<i>Scene</i>	
	Hospitals and dental surgeries (anaesthetic gases), industrial sites, laboratories, mines. Victims found in bathrooms, boats, caravans, cars, fires, kitchens. Presence of fire extinguishers, gas fires, geysers, portable heaters
<i>Occupation</i>	
	Chemical industry, electroplating, fumigation, furnaces, glue factories, industrial tank cleaning, jewellery, metal treatment, mines, photography, sewers, tanneries
<i>Additional investigations</i>	
	Examination of equipment or vehicle Examination of clothing if stained or if odours are noted Postmortem
<i>Analysis</i>	
Odour	Carbon monoxide, cyanide
Colour tests	Direct reading colorimetric indicator
Group tests	Not available
General methods	Diffusion in Conway cell (cyanide), head-space gas chromatography
<i>Commonest poisons</i>	
Number of compounds reported	5
Number of compounds to be excluded	30

Some compounds which are gases at normal temperature and pressure can be detected by head-space gas chromatography (p. 187), using Systems GA or GI (p. 199). System GI will detect butane, ethane, methane, nitrous oxide, and propane, and

also several of the low boiling-point fluorocarbons in blood samples.

Only two poisons in this group require routine exclusion. These are cyanide and carbon monoxide. The main exceptions to this general recommendation are cases arising from an incident on industrial premises, or the use and abuse of compressed solvent fuels and aerosols. In the former case, a list of the industrial gases used or available on site should be requested; in the latter case, most of the relevant compounds are covered by head-space gas chromatography as mentioned above.

CARBON MONOXIDE

The detection and measurement of carbon monoxide in blood samples is frequently required in forensic toxicology for the investigation of deaths in fires, cars, caravans, etc. and it is essential for all routine screening schemes. A preliminary colour test may be used (p. 6), but the most rapid and convenient method of detecting and quantifying carbon monoxide as a primary or secondary cause of poisoning is by using a spectrophotometric method (p. 20).

CYANIDE

In most cases this poison is self-indicating by its odour of bitter almonds. However, there is a very variable ability amongst the population to detect cyanide by its odour, so a colour test is useful (p. 65). For blood and tissue specimens it is preferable to use the quantitative method using Conway micro-diffusion cells (p. 65).

Group 2 Poisons: Volatile Compounds

Rapid onset of symptoms, followed by serious illness or death is the most valuable clue to the presence of this group. The probable identity of the particular poison may be indicated by the nature of the symptoms (Table 2). Physical evidence at the scene (e.g. bottles, residues in cups, etc., tubes of adhesives, and plastic bags with characteristic odours) frequently leaves little doubt of the nature of the intoxicant, if the material is submitted within 48 hours. If death has been delayed for several days by hospital treatment, it is imperative to obtain for analysis any antemortem samples taken on admission to hospital, no matter how small.

If several days have elapsed before the body is discovered, there is a tendency to think that analysis for volatile poisons would be futile. In fact it should be one of the first groups to be checked. The presence of alcohols, toluene, and halogenated hydrocarbons

Table 2. Group 2 Poisons: Volatile Compounds

<i>Indications</i>	
Symptoms	Abdominal pain (especially with phenols), convulsions (especially with glycols), delirium, drunken behaviour (drowsiness, ataxia, speech and vision disturbance), jaundice (aniline, nitrobenzene), tremors, vomiting
Onset of symptoms	Rapid onset of illness or death when inhaled, slower if taken orally
Clinical history	Alcoholism; 'glue-sniffing' habit (more common in children and teenagers)
Scene	Domestic locations; hospitals and research laboratories; industrial locations. Presence of liquor, methylated spirit or surgical spirit; glues or polishes associated with plastic bags; unusual siting of anti-freeze or other domestic products
Occupation	Degreasing plants, dry cleaners, printing; manufacturer of adhesives, dyes, paints, petroleum products, plastics, polishes, perfumes, rubber
Additional investigations	Bottles or containers found near victim, even if empty Examination of clothing if stained or if odours are noted Antemortem examination of blood or urine samples Postmortem examination of lung and brain specimens; also vitreous humour, especially if the body is decomposed
<i>Analysis</i>	
Odour	
Colour tests	Dichromate test for ethanol, aldehydes, and ketones; colorimetric indicator tube (e.g. Alcotest); Fujiwara test for trichloro-compounds
Group tests	Head-space gas chromatography
General methods	Gas chromatography
Commonest poisons	Chloral hydrate, ethanol, methanol, toluene
Number of compounds reported	25
Number of compounds to be excluded	60

has been shown in many such samples, although the interpretation of the detected concentrations may present problems. Special care is needed if the samples have been frozen; volatile poisons may be missed if the analytical material is not allowed to thaw, preferably at room temperature, before examination. The frequent abuse of toluene, acetone, and other solvents associated with the 'glue-sniffing' habit should be remembered in all poisoning cases. Because the addict is now turning his attention

to a wide variety of industrial solvents, a good general screening method backed up with a large data base is required. Gas chromatography is the only way of achieving this coverage since all other methods require the application of separate colour tests or chemical reactions for each volatile substance.

Head-space gas chromatography (p. 187) is probably the most widely used method for general screening of volatile poisons. Systems GA or GI (p. 199) may be used. Steam distillation of the sample prior to analysis by gas chromatography can be helpful with the less volatile materials.

Group 3 Poisons: Drugs (Solvent Soluble)

In general, postmortem stomach contents, blood, and urine samples may be analysed by immune-assay (see under Immunoassays, p. 148), and by the same methods as those detailed for patients' samples (see under Hospital Toxicology and Drug Abuse Screening, p. 3), provided that the objective is identical, i.e. to obtain evidence of a drug overdose (Table 3). However, in some suspicious deaths or criminal cases, stomach contents, blood, and urine samples cannot be obtained and tissue samples have to be examined. Most screening systems for biological fluids are easily modified by the introduction of a few additional clean-up procedures to permit the utilisation of homogenates of liver or other tissues. There is much to be said for having a few routine extraction methods of general applicability rather than a large number of detailed methods each designed for a specific purpose. The inherent defects of a few routine systems are soon discovered through constant use, but this is preferable to the unknown defects of a multiplicity of systems which are rarely used. Enzymatic digestion allows the extension of stomach content, blood, and urine extraction routines to samples of solid tissue.

Table 3. Group 3 Poisons: Drugs (Solvent Soluble)

<i>Indications</i>	
Symptoms	Effects are variable but the following information may be
Analgesics	Gastric irritation, haematuria, tinnitus, sweating, coma,
Opiates and synthetic narcotics	Contracted pupils, muscle twitching, slow respiration, hypotension, coma
Sedatives and hypnotics	Ataxia, slurred speech, drowsiness, stupor, coma
Stimulants and antidepressants	Dilated pupils, dry mouth, headache, tachycardia, tremors,
Onset of symptoms	Relatively slow unless injected (i.e. 2 to 48 hours)

Indications

Age	Illicit drugs more common in 16 to 30 age group. The elderly use
Scene	Illegal lodgings, colleges, discos, clubs, mental homes
Additional investigations	Antemortem samples if the victim is admitted to hospital. Postmortem examination of nasal swabs, injection marks and a control area of skin

Analysis

Colour tests	No general tests, only selective tests for salicylates, phenothiazines, sulphonamides, etc.
Group tests	Direct solvent extraction and examination by TLC and immunoassay Confirmation and quantification by UV, GC, HPLC, MS
Commonest poisons	Amitriptyline, amyl barbitone, butobarb-itone, diazepam, imipramine, morphine, orphenadrine, paracetamol, pentobarb-itone, quin albarbitone, salicylates

Number of compounds reported	200
Number of compounds to be excluded	>1000

TISSUE ANALYSIS

Direct solvent extraction before or after acid or enzymatic digestion has almost superseded the classic protein precipitation methods. Due to the more sensitive detection methods of gas chromatography and mass spectrometry, much smaller amounts of tissue can be processed. Consequently, any emulsion problems that arise are more easily resolved than in the past when several hundred grams of liver and large volumes of solvent were required.

Enzymatic Digestion. This method is usually the best choice for general screening. It is simple, readily adaptable, and gives a protein-free filtrate from which any drugs present may be extracted. It also gives enhanced extraction of many drugs compared with the tungstate, ammonium sulphate, or Stas-Otto methods.

A suitable procedure is as follows: macerate 10 g of liver or other tissue with 40 ml of M tris(hydroxymethyl)methylamine; add 10mg of Subtilisin A (see Reagent Appendix) and incubate in a water-bath at 50° to 60° for about one hour, with agitation. Filter the digest through a small plug of glass wool to remove undissolved connective tissue.

Aliquots of this digest may be substituted for the specified biological fluid in most routine screening

procedures. The filtered digest has a pH of 8.0 to 9.5. This method is very useful for the analysis of sectioned injection marks. The superficial fatty skin layer is removed and the remaining muscle layer analysed as above. If the injection was intramuscular and of recent origin, the drug concentrations should be greater than in a similar tissue sample not showing an injection mark. If the injection was intravenous, such a distinction cannot be expected.

The method's superb ability to 'liquidise' solid tissue can be used for many purposes apart from drug analysis. The recovery of shot-gun pellets and small bomb fragments in body tissues is one such application. The preparation of solutions for direct aspiration into atomic absorption instruments for the detection of some metals has been studied. Its use for the detection of toxic anions and some pesticides also seems feasible.

GENERAL DRUG SCREENS

A multipurpose drug screen such as Scheme 2 (p. 10) may be applied to samples of body fluids, especially when there is a limited amount of sample.

DRUG SCREENING IN NON-FATAL CRIMINAL CASES AND TRAFFIC OFFENCES

Many forensic enquiries entail analytical investigations which require detection of therapeutic drug concentrations rather than toxic concentrations. For example, in driving offences a screen is required for drugs which can impair judgement and psychomotor activities (e.g. sedatives, tranquillisers, stimulants, and narcotics). This type of analysis may also be needed to check allegations that the victim or accused is a drug addict or was under the influence of drugs at the time of the crime. The amount of blood and urine available for analysis in these cases is usually very limited and irreplaceable; additional samples taken several days after the event are useless.

Background information is of paramount importance, and the following information should be requested as a matter of routine. Were there any drugs in the possession of the victim or the defendant? What was the subject's condition (e.g. drowsy, asleep, confused, agitated, etc.)? Did the police doctor certify impairment of driving ability? Is the subject prescribed any drugs by his own doctor and, if so, when was the last dose taken? Is the subject a known drug addict?

When the identity of the suspect drug is not known before analysis, the successful detection of therapeutic concentrations of many of the basic drugs in blood alone is extremely difficult. Blood and urine

samples should be obtained whenever possible in this type of investigation; when the blood sample is small, the chance of detecting and confirming residual traces of some antidepressant or stimulant drug is almost zero. If there is no urine sample, pre-screening by radioimmunoassay methods is essential to provide an analytical guide to the nature of any drug present in the blood sample.

For forensic purposes, at least two uncorrelated methods of identification are required (e.g. TLC and GC, or GC and MS). Immunoassay methods provide good exclusion evidence, but poor confirmation of identity, although they are vital for the detection of insulin, lysergide, and the cannabinoids.

When drug concentrations are liable to be low, the extraction of separate aliquots of urine or stomach contents is recommended (Scheme 1, p. 46).

Group 4 Poisons: Metals

Historically, poisons in this group (Table 4) have been used frequently, probably because in general they are potent, tasteless, readily available, and produce symptoms similar to many common diseases. Consequently, suspicion is rarely aroused until it is too late.

For example, the substitution of arsenious oxide for the contents of one or two prescribed capsules can have fatal results with all the appearance of a straightforward drug overdose suicide. A drug-screen analysis in these circumstances will result in a very perplexed analyst and a lot of wasted time and case material. This is not a theoretical possibility, it has happened on more than one occasion!

Table 4. Group 4 Poisons: Metals

<i>Indications</i>	
Symptoms	Anaemia, cramps, diarrhoea, gastric pain, hair loss (thallium and selenium), jaundice, metallic taste, paralysis, peripheral neuritis, salivation, urine retention, vomiting, weight loss
Onset of symptoms	Usually after several hours; death may occur within 24 hours but more commonly after several days
Scene	Industrial locations, laboratories
Occupation	Electroplating, smelting, manufacture of agricultural chemicals, alloys, batteries, ceramics, glass, paint, petroleum products
Additional investigations	Antemortem examination of blood and urine. Postmortem examination of kidney, intestinal contents, bone, hair, nails

Table 4 (continued)

<i>Analysis</i>	
Colour test	Reinsch Test
Group test	Atomic emission spectroscopy
Commonest poisons	Arsenic, antimony, lead, lithium, mercury, thallium
Number of compounds reported	9
Number of compounds to be excluded.	20

Group 4 poisons should be checked as a matter of routine if vomiting and diarrhoea are noted as symptoms, no matter what other poisons may be suggested by medical opinion or circumstantial evidence. Although the Reinsch Test (p. 57) will detect only seven of the twenty potentially toxic metals, it can be applied to almost any material (body fluids, slurried tissue, food and drinks) without any elaborate preparation, and it is sensitive enough to detect toxic concentrations of the most common poisonous metals in a few minutes. However, it misses too many metals for it to be considered as a complete group exclusion test.

If the suspect metal is specified, a laboratory equipped with atomic absorption spectrophotometry should have little difficulty in confirming the medical or police suspicions. Details of the identification and quantification of the most common metal poisons are given under Metals and Anions (p. 56).

However, the clinical symptoms are often not specific for the diagnosis of the actual metal involved and circumstantial evidence may be unavailable. In many forensic toxicological investigations there is, therefore, a requirement for a general screening method for metals.

A satisfactory routine metal screening method must be capable of analysing any biological material, without drastic modifications and with detection limits which provide reliable exclusion of minimum quoted toxic concentrations. Fortunately for most metals the lower threshold of toxicity is at least an order of magnitude higher than the normal level. A semi-quantitative rapid screening method for metals in biological samples using atomic emission spectroscopy is described on p. 56.

Group 5 Poisons: Pesticides (Solvent Soluble)

Most of the published work on the analysis of pesticides (insecticides, herbicides, rodenticides, etc.) makes the assumption that the analyst knows the identity of the actual compound or that he has some knowledge of the particular

type of pesticide present in his analytical sample. This is rarely true in forensic work and until this information has been obtained, many excellent published methods are not suitable. This group is illustrated in Table 5.

Table 5. Group 5 Poisons: Pesticides (Solvent Soluble)

<i>Indications</i>	
Symptoms	Principal features are vomiting and convulsions. The following additional symptoms may be used as a guide:
Chlorinated hydrocarbons	Dizziness, headache, muscular weakness, tremors
Chlorinated phenoxyacetic acids	Burning sensation, low blood pressure (convulsions are not a main feature for these substances)
Organophosphates	Contracted pupils, salivation, sweating, dyspnoea, anoxia, cyanosis
Phenols and cresols	Fever (main symptom), thirst, sweating, anoxia, haematuria, jaundice
Onset of symptoms	Rapid (within 30 minutes) if product contains a petroleum solvent or is inhaled, Otherwise, slow (1 to 6 hours)
Scene	Farms and horticultural nurseries, food processing factories, domestic premises
Occupation	Manufacture of agricultural chemicals, farm workers, gardeners, pesticide officers
Additional investigations	Stained clothing, vomit, drink, stomach contents
<i>Analysis</i>	
Visual appearance	Abnormal colours in food, drink, or stomach contents (pesticides often contain dyes)
Odour	Hydrocarbon solvents or odours which are fishy, sulphide, or urine-like
Colour tests	Fujiwara test for trichloro-compounds Sulphuric Acid-Fuming Sulphuric Acid Test for aldrin, dieldrin, and endrin Cholinesterase inhibition test for organophosphates Dithionite test for paraquat and diquat
Group tests	Ultraviolet spectrophotometry, gas chromatography (see chapter on Pesticides)
General methods	Solvent extraction; most pesticides extract into acid and neutral groups
Commonest poisons	Chlordane, dichlorophenoxyacetic acid, lindane, mevinphos, nicotine, paraquat, parathion, trichlorophenoxyacetic acid
Number of compounds reported	20
Number of compounds to be excluded	>500

With the exception of the world's poor peasant populations who have little access to modern synthetic drugs, few people with suicidal intentions choose to use pesticides for this purpose. This is not true of poisoners; in fact many of the chemicals used for homicidal poisoning have been pesticides. Arsenic, thallium, phosphorus, and strychnine preparations have been used as rodenticides, and nicotine and mercury salts as insecticides and fungicides. The criminal use of the herbicides sodium chlorate and paraquat is fairly common, and only a few years after its commercial introduction as an insecticide, parathion was used to commit a murder. Contrary to popular opinion, many malicious poisonings are not premeditated. The necessary warning labels present by law on most pesticide containers seem to provide an irresistible temptation to the neighbour seeking revenge, or to the jealous lover. The solvent soluble pesticides must therefore be considered in the forensic investigation of a malicious food poisoning, sudden illness, or suspicious death. An exclusion screening method, rather than a series of individual tests, is of vital importance. In view of the criminal use of pesticides in the past, the discrepancy between the number of pesticides available and the number actually detected in criminal cases is perhaps an alarming indication of how few forensic science laboratories have an adequate routine method. The analysis of pesticides is described under Pesticides (p. 71).

Group 6 Poisons: Anions

The medicinal use of bromides and other toxic anions has declined, but most of the substances in this group are still readily available, and poisoning cases do still occur. However, detailed information on actual cases (blood and tissue concentrations etc.) is scarce. This may be because most of these poisonous salts are taken in such large amounts that their presence is usually indicated by the circumstantial evidence, and so analytical confirmation is not sought. Conventional inorganic tests applied to a filtered sample of the contents of the gastro-intestinal tract will often suffice to confirm a diagnosis. Nevertheless, an attempt at isolation, identification, and quantification in blood and tissues should be made to assist in the interpretation of an atypical case where symptoms and circumstances do not provide the usual clues. The forensic toxicologist in particular should remember Orfila's maxim - "The presence of a poison must be proved in the blood

and organs before it can be considered as a cause of death."

The toxic dose of most of the chemicals in this group is relatively large, about one or two teaspoon-fuls. This may explain why, with the exception of chlorates and fluorides, they have not featured in many homicidal poisonings. However, toxic anions occur quite commonly in malicious poisoning cases[^] so food, drink, vomit, stomach washings, gastric aspirates, and urine should always be examined for their presence. In non-fatal cases, blood samples are usually inadequate, and should be reserved until the results of the work on other samples is known. Table 6 summarises the common features of this group. The diphenylamine test for oxidising agents (p. 5) has a sensitivity of about 1 ppm and, if negative, excludes most of the toxic anions in this group.

Table 6. Group 6 Poisons: Anions

<i>Indications</i>	
Symptoms	Violent vomiting, diarrhoea, abdominal pain, cyanosis (methaemoglobin formed with oxidising agents), stained skin and mucosa (permanganate, oxalate, iodide, and bleaching agents) Exceptions to these symptoms are fluoride and bromide
Onset of symptoms	Usually within one hour, death may occur within several hours (note that the toxic dose of this group is relatively large, >10g)
Scene	Agricultural sites (nitrate, chlorate, fluoride, and fluoroacetate) Industrial sites (nitrite, oxalate, and sulphite) Domestic sites, drain and lavatory cleaners (hypochlorite and persulphate), weed killers (chlorate), insect powders (fluoride) Laboratory
Occupation	Sewer workers, rat catchers (fluoroacetate), factory workers
Additional investigations	Vomit, stained clothing, cups, etc. found near victim, stomach contents or washings, antemortem blood
<i>Analysis</i>	
Visual evidence	Chocolate-coloured blood, blood-stained vomit or urine, crystalline residues in food and drink
Colour test	Diphenylamine test for oxidising agents which covers about 50% of the group
Group tests	Not available
Number of compounds reported	7
Number of compounds to be excluded	15

A method for the isolation of toxic anions by dialysis, and procedures for identification and quantification are given under Metals and Anions

In non-fatal poisoning cases/the sample of food, vomit, etc. may be very limited. If this is the case, the sequential method described under Examination of Food and Drink, below, should be used.

EXAMINATION OF FOOD AND DRINK

Most malicious poisoning cases involve the addition of toxic substances to food or drink. The analysis of suspected poisoned food or drink presents different problems from the detection of drugs and poisons in body fluids. The concentration of the toxic agent is usually higher than that found in blood, urine, or postmortem tissue samples, but the available material for analysis is often more limited, and of much greater variety. The routine analysis of blood and urine samples soon ensures recognition of endogenous substances (urea, tryptamine, cholesterol, etc.) and of common exogenous chemicals such as caffeine and nicotine when they occur in extracts, spectra, and chromatograms. But one scarcely knows what to expect from the analysis of chicken curry or chocolate gâteau. Packet labels demonstrate that even simple foodstuff's may contain several unfamiliar chemical additives. The parallel analysis of a purchased sample of the same food may be necessary to check that inexplicable reactions or unfamiliar spectra are normal or abnormal for that type of material.

Before starting the analysis every effort should be made to obtain details of the circumstances leading to the complaint or suspicion of doping or poisoning. Every case must be accompanied by an enquiry form similar to that shown on p. 39, and this should be supported, when possible, by an interview with the police officer. Was the suspect material tasted? If not, what aroused suspicion? Is the victim ill? What are the symptoms? Without clues to guide the selection of tests and screening systems, the sample is a 'general unknown'.

Depending on the case history, it is sometimes useful to request a urine and a blood sample from the victim; they may have been poisoned, but not by the food or drink submitted for analysis! Alternatively, the food may contain a poison, but there may not be any evidence of the poison in their blood or urine. Fake poisonings are not uncommon, especially in marital cases. Another type of fake poisoning is the misguided joke of putting some obnoxious material (e.g. urine, aloes, soap, mustard, etc.) into a person's food or drink.

About 10 g of food or 10 ml of drink (which may be all that is available) is adequate, providing that there is some guide to the nature of the poison. However, this would not be sufficient for twenty or thirty individual colour tests. A drug screen alone is not sufficient, unless the circumstantial evidence indicates that the intention was to dope rather than to poison the victim. The method must utilise techniques which are non-destructive and eliminate large numbers of compounds.

The method described below is designed to obtain the maximum amount of analytical data from the minimum quantity of material. It is very flexible and can be applied to tea, coffee, milk, alcoholic drinks, sandwiches, cakes, pies, sausages, and numerous other types of food. Vomit and food stains may also be examined.

Analytical Procedure

Make a full description of the exhibit, noting type of container, labels, seals, stains or identification marks on the outer surface, and total volume and/or weight. Note the colour, odour, presence or absence of suspended solids or sediment, pH, and whether material has a tendency to form a stable froth on shaking.

COLOUR

The presence of abnormal colours may indicate the presence of inorganic pigments (e.g. copper, nickel, or cobalt salts), dyestuffs from tablets, capsules, medicines, pesticides, and rodent baits, especially those containing warfarin, reserpine, chloralose, or diphenadione. Common rat-bait colours are blue, green, or red and are usually associated with oatmeal or cereal grain.

ODOUR

Material taken straight from the refrigerator should be warmed gently prior to examination for odour. If possible, the opinions of several colleagues should be obtained on any abnormal odour. Many poisons can be detected in this way, but the test is very subjective, and some people have a poor sense of smell (e.g. cyanide detection by odour is an inherited ability). In favourable circumstances it is a very sensitive test; for instance, cyanide, chloroform, and toluene can be detected at about 1 ppm. Apart from the usual characteristic odours of sulphides, aldehydes, ketones, and esters, etc., the analyst should be familiar with the smell of chloral hydrate, ethchlorvynol, methylpentynol, phenelzine,

thiamine, penicillamine, penicillins and other common antibiotics. The latter compounds are typical of substances found in joke or fake poisonings.

These cases can be most frustrating to the analyst for a negative report cannot be given when there is a most obvious detectable abnormal odour whose source has not been identified. If the material has a distinct odour, a comparative head-space gas chromatographic screen is indicated.

SEDIMENTS AND SUSPENSIONS

Sediments may be due to insoluble or sparingly soluble tablet or capsule excipients such as talc, starch, or calcium phosphate, certain poisons such as arsenious oxide, or sometimes to an interaction of the added contaminant with the beverage or drink (e.g. battery acid producing a coagulation of protein material). Microscopic examination of the sediment or filtered suspension may give a clue to the nature of the material.

The presence of insoluble inorganic crystalline sediments is often due to the addition of cleaning powders (especially when accompanied by a faint odour of bleach or ammonia). Nevertheless, a spectrographic analysis for metals should be undertaken at some stage (p. 53). When crystalline material can be isolated from the material under examination, X-ray diffraction and infra-red spectrophotometry are valuable non-destructive techniques if they are readily available and are backed up by good spectral libraries.

FROTHING

The presence of stable froth when the sample is shaken (with water if necessary) may indicate contamination with soap or detergents. Acidify the sample, shake again, and if froth still forms, a detergent rather than soap is present. Although of low toxicity, soap, detergents, and cleaning powders are frequently the cause of complaints of poisoning.

DIRECT ULTRAVIOLET SPECTROPHOTOMETRY

In poisoned food or drink samples, concentrations of 0.1 to 10% are not uncommon so that direct ultraviolet spectrophotometry may often be used. This is in contrast to biological samples for which prior solvent extraction is required because of the very low concentrations (less than 0.01%). If a sample of food contains a foreign substance with an

$A_1 > 200$, and it is present at a concentration of 0.1%, the material may be diluted 50 times and still show the characteristic spectrum for that

substance when examined by direct ultraviolet spectrophotometry. This is a very useful, rapid and non-destructive exclusion method for the large number of drugs, disinfectants, and pesticides with high specific absorbances.

Direct ultraviolet spectrophotometry is invaluable as an initial screening technique for all alcoholic drinks, and for beverages such as tea, coffee, milk, and soup. It may also be applied to solid foods (cakes, sweets, bread, etc.), and to complete meals (meat, stews, vegetables) either by application to a diluted homogenate or by examination of a copious water-wash of the food material. The latter method is preferable as most poisoners tend to sprinkle the poison on the surface of the food rather than adding it during the cooking process. A note of the weight of the material used and the volume of added water should be made to facilitate calculation of the approximate quantity of poison present.

If possible, a control sample of the particular food or drink should be examined at the same time. If the spectra obtained with the control sample are similar to those obtained with the sample, a large number of substances are excluded (Table 7) without loss or destruction of what may be an extremely limited amount of original material.

Table 7. Some compounds detectable in food and drink by direct ultraviolet spectrophotometry

Analgesics: acetanilide, aspirin, benorylate, cinchophen, etenzamide, ethoxazene, flufenamic acid, mefenamic acid, paracetamol, phenacetin, phenazone, phenylbutazone, propyphenazone, salicylamide, salicylic acid

Antidepressants: amitriptyline, butriptyline, clomipramine, des-ipramine, dibenzepin, dothiepin, doxepin, imipramine, iprin-dole, isocarboxazid, maprotiline, nortriptyline, opipramol, protriptyline, trimipramine

Antidiabetics: acetoexamide, chlorpropamide, metformin, tol-butamide

Antihistamines: antazoline, carbinoxamine, chloropyrilene, chlorpheniramine, cyproheptadine, dimethothiazine, diphenhydramine, doxylamine, isothipendyl, mepyramine, methapyrilene, promethazine, trimeprazine, tripeleminamine, triprolidine

Antimalarials: amodiaquine, chloroquine, chlorproguanil, cinchonidine, cinchonine, primaquine, proguanil, pyrimethamine, quinine

Barbiturates: all

Benzodiazepines: all

Disinfectants: acriflavine, aminacrine, chlorhexidine, chloroxy-lenol, cresol, dofamium chloride, domiphen bromide, hexa-chlorophane, parachlorophenol, phenol, proflavine

Diuretics: amiloride, bendrofluazide, benzthiazide, chlorothiazide, clopamide, cyclopenthiazide, cyclothiazide, ethacrynic acid, frusemide, hydrochlorothiazide, polythiazide, quinethazone, spironolactone, triamterene

Local anaesthetics: benzocaine, butacaine, chloroprocaine, cinchocaine, cocaine, cyclomethycaine, dimethisoquin, dipiperdon, dyclonine, lignocaine

Table 7 (continued)

Pesticides and herbicides: ametryne, atrazine, benzyl benzoate,

carbaryl, demeton-S, desmetryne, dinitro-orthocresol, diquat, methoprotrotyne, nicotine, paraquat, pentachlorophenol, rotenone, simazine, terbutryne

Purgatives: aloin, bisacodyl, danthron, oxyphenisatin, phenolphthalein

Rodenticides: coumatetralyl, diphenadione, warfarin

Sulphonamides all

Tranquillisers: benperidol, captodiamine, clopenthixol, flupenthixol, haloperidol, phenothiazines, prothipendyl, trifluoperidol

Vitamins: acetomenaphthone, ascorbic acid, ergocalciferol, nicotinamide, pyridoxine, riboflavine, thiamine

Xanthines: acepifylline, bamifylline, bufylline, caffeine, diprophylline, etamiphylline, theobromine, theophylline

Miscellaneous substances: aminosalicic acid, benzoic acid, betanaphthol, carbamazepine, chlorphenesin, dibromopropamide, diethylpropion, halquinol, isoniazid, methaqualone, metronidazole

COLOUR TESTS

After ultraviolet spectrophotometry, the diluted liquid or washings is available for further preliminary tests, using a small aliquot for each test.

1. Apply the Fujiwara Test for trichloro-compounds (p. 135). The aqueous layer in this test can be used to test for the presence of oxalate (p. 67).
2. Apply the Diphenylamine Test for oxidising agents (p. 132).
3. Test for the presence of halides with silver nitrate (p. 64).

Warm the main bulk of the sample on a water-bath, note any odour, and test the sample with appropriate test papers (pH, lead acetate, silver nitrate, starch). Apply the Reinsch Test for metals (p. 57).

After the application of the Reinsch Test, filter the sample and retain the solids and the filter paper. Use small aliquots of the filtrate to test for borate (p. 64), and phosphate.

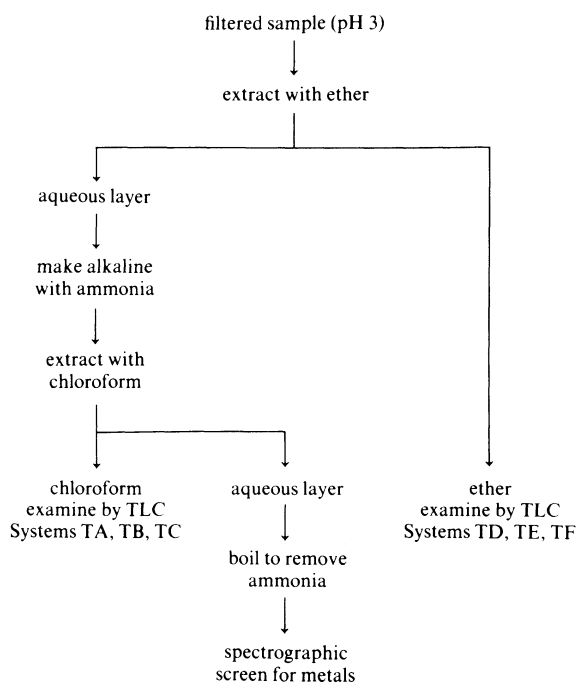

EXTRACTION SCHEME

The preliminary observations often allow the tentative identification of a poison so that specific tests can then be made. If this is not so, the extraction procedure outlined below should be applied to the filtrate obtained above.

ANALYSIS OF TABLETS AND CAPSULES

Excipients. Most tablets and capsules are complex mixtures containing a small amount of one or more drugs together with a larger amount of excipients. The following substances are frequently used as excipients.

Adhesives/binders: acacia, ethylcellulose, gelatin, liquid glucose, methylcellulose, polyethylene gly-

Scheme for the extraction of toxic substances in food and drink

Details of the thin-layer systems are given on pp. 167 to 169, and information on a spectrographic screen for metals on p.56.

cols, polyvinyl pyrrolidone, sodium alginate, sodium carboxymethylcellulose, starch, and starch derivatives.

Diluents: calcium phosphate, calcium hydrogen phosphate, calcium sulphate, glucose, kaolin, lactose, mannitol, colloidal silica, sodium chloride, sodium sulphate, sorbitol.

Disintegrating and wetting agents: agar, alginic acid, bentonite, microcrystalline cellulose, gelatin, magnesium aluminium silicate, methylcellulose, sodium lauryl sulphate, starch, and starch derivatives.

Glidants and lubricants: boric acid, colloidal silica, hydrogenated vegetable oils, magnesium stearate, polyethylene glycols, stearic acid, talc.

Flavouring agents: cocoa, glucose, liquorice powder, sodium citrate, sucrose.

A combination of visual and microscopic examination, colour tests, chromatography, and ultraviolet and infra-red spectrophotometry is employed in the analysis. If the preparation is fairly common and does not contain a complex mixture of drugs, two or three of these techniques will usually succeed in establishing the identity of the tablet or

indicating the nature of the drug or drugs it contains. The first step is to make careful notes about the container and its contents.

Container. This may be a tube, envelope, folded paper packet, box, or bottle. Note any seals and labels. Make full notes of the information given on the label.

Contents. Note the total number of tablets or other preparation in the container, together with an estimate of the total number which the container could hold if filled. Note the shape (flat, bevelled, biconvex, etc.), whether compression-coated, film-coated, enteric-coated, or sugar-coated, markings (numbers, letters, symbols, or score marks), exterior and interior colour, layered and core tablets, and mean weight, diameter, and thickness.

Visual Recognition

This can only be regarded as a useful clue; even tablets with well-known brand names may be faked, and placebo tablets are sometimes made. Every laboratory should maintain a reference collection of authentic tablets and capsules and reference can be made to published collections of tablet identification data. If the container bears the name of the pharmaceutical manufacturer a telephone call giving the details of the tablets (even if they are unmarked white ones) may enable the firm to suggest a limited number of their products sold in that form. Especial care is required with capsules because their contents may readily be changed. (Arsenic, cyanide, and lysergide have been substituted in the past.)

The analyst should be aware of certain less common preparations which may be encountered. *Homoeopathic Preparations.* These are usually round, flat/flat tablets with rough surfaces, 5 to 6 mm in diameter, and contain mainly lactose. *Injection Tablets.* Small, totally soluble tablets used for making solutions for injection. The most commonly encountered until recently were diamorphine tablets. These were round, flat/flat tablets, 4 mm in diameter and 2 mm thick, weighing 30 mg. They have been discontinued but they may still be seen, having been burgled from pharmacies. These tablets should not be confused with LSD microdots which are usually highly coloured.

Health Food Preparations. These usually contain vitamins, minerals, herbal extracts, yeast, etc. There are too many different brands to incorporate in any collection. *Sex-shop Preparations.* These usually contain substances reputed to be aphrodisiacs such as vitamin E and ginseng.

Non-medicinal Preparations. These include a variety of preparations such as sweetener tablets, fertiliser tablets, stink bombs, indoor fireworks, and slug pellets.

Analytical Procedure

MICROSCOPIC EXAMINATION

Place a small amount of a crushed tablet or capsule contents on a slide, mix with a drop of water, and cover carefully with a cover-slip avoiding trapped air bubbles. Observe under low-power magnification. Effervescence will be obvious. If crystalline material is visible, note if it is water-soluble. Check the pH of the solution. An alkaline reaction may indicate the presence of a sodium salt of an acidic drug. Introduce a small drop of *silver nitrate solution* along one edge of the cover-slip; a visible precipitate indicates the possible presence of a hydrochloride salt of a basic drug.

Note the presence of any organised plant material. In most cases this will be corn (maize) or wheat starch which can be confirmed by the blue colour obtained with iodine solution or by examination under polarised light (starch grains exhibit a distorted cross). The ability to recognise the various commercial starches is a useful skill. The presence of a large amount of uncooked starch grains in a sample of stomach contents often provides a useful clue to the ingestion of an unsuspected overdose of tablets or capsules, even when the deceased survived for several hours after their ingestion.

The presence of other types of plant material indicates the tablet is probably a herbal remedy. These are frequently very complex mixtures and are unlikely to be identified by the simple methods proposed in this chapter. However, the examination of an alcohol extract by ultraviolet spectrophotometry and thin-layer chromatography is worth attempting.

ODOUR

A few drugs have distinctive odours and this can provide a clue to the compound or at least to the type of preparation. A yeast-like or meaty smell may indicate a harmless vitamin preparation, an odour of peppermint may indicate a non-toxic indigestion remedy. Antibiotics, especially of the penicillin group, sometimes have a rather unpleasant sulphide-type smell. Other drugs with characteristic odours are chlormethiazole, phenelzine, ethchlorvynol, chloral hydrate, and methylpentynol.

SIZE

The size of the tablet, which should be measured with callipers having a vernier reading to 0.1 mm, can provide a rough guide to the general class of preparation. Large diameter tablets (i.e. > 10 mm) are unlikely to contain potent alkaloids (except codeine) and conversely, tablets with diameters less than 5 mm could not contain drugs with medicinal doses of 200 mg or more. There is an approximate correlation between tablet diameter and the amount of drug contained in the tablet (Table 8), and this may be used as a rough guide.

Table 8. Relationship between tablet diameter and probable drug content

Tablet diameter mm	Probable drug content mg
less than 6	less than 5
„ „ 7	„ „ 15
„ „ 8	15 to 100
„ „ 9	30 to 200
„ „ 10	200 to 300
greater than 11	250 to 500

A useful table of tablet diameters and related drug content is given in *The Pharmaceutical Codex*, 11th Edn, London, The Pharmaceutical Press, 1979, pp. 909-912.

COLOUR TESTS

These should be tried only if an adequate number of tablets or capsules is available, as they are destructive tests. They may provide a clue to the identity of the unknown but they are rarely specific. However, they are useful when the appearance or markings suggest an identity.

1. Heat some of the powdered material on a metal spatula. Little or no charring is indicative of an inorganic preparation.
2. Marquis Test (p. 139). Many basic drugs produce colours with this reagent. It is a good test for opiates, stimulants, antihistamines, and pheno-thiazines.
3. Koppanyi-Zwicker Test (p. 135) for barbiturates and sulphonamides.
4. Mercurous Nitrate (p. 140) and Nitrous Acid (p. 143) for sulphonamides.
5. Ferric Chloride (p. 133) for phenols.
6. Forrest Reagent (p. 134) or FPN Reagent (p. 134) for phenothiazines.

7. Iodoplatinate Test (p. 135). This is a valuable test if the test material does not contain starch. If a colour is not obtained, most of the basic narcotic, antidepressant, antihistamine, and tranquilliser drugs can be eliminated.

EXTRACTION OF TABLETS AND CAPSULES

Elaborate solvent fractionation schemes are not usually necessary for solid dosage preparations. Most drugs are soluble in methanol and most of the excipients are not; therefore the preparation of a simple methanol extract is all that is required. However, if the methanol extract is too concentrated, the spot on the TLC plate will be overloaded and the resultant chromatogram will be useless. Any subsequent ultraviolet spectrophotometric examination of the extract may give spectra which are not on scale. This cannot always be avoided, but the following guide-lines have been found useful.

If a possible identity is suggested by the case notes or by visual examination of the sample, check the published content of medicament and adjust the amount of methanol to produce an approximate concentration of 1 to 20 mg/ml.

If there are no clues to the identity (e.g. a plain white tablet), measure the diameter. For a diameter of 5 to 6 mm, use 1 or 2 ml of methanol per tablet; for diameters of 8 to 9 mm, use about half a tablet in 5 to 10 ml of methanol; for diameters greater than 9 mm, use about one quarter of a tablet in 20 ml of methanol.

THIN-LAYER CHROMATOGRAPHY

The great majority of drugs present in pharmaceutical products are nitrogenous bases. The extract should be examined, therefore, by Systems TA, TB, or TC (p. 167). If these fail to reveal any positive reacting spots with the suggested location reagents, the possible identity of the unknown substance is reduced from a large number of basic drugs to a few hundred acidic and neutral drugs. The extract should then be examined by Systems TD, TE, or TF (p. 168).

ULTRAVIOLET SPECTROPHOTOMETRY

A portion of the methanol extract is diluted with water and examined at both acid and alkaline pH by ultraviolet spectrophotometry. The features of any resultant spectrum should be checked in the index to Ultraviolet Absorption Data in Part 3. If the identity is suspected, the spectrum may be compared with that given in the monograph in Part 2.

INFRA-RED SPECTROPHOTOMETRY

Extract a small portion of the crushed tablet or capsule contents with chloroform; to a portion of the chloroform extract add solid potassium bromide, dry under an infra-red lamp, prepare a compressed disk, and examine by infra-red spectro-photometry. The features of any resultant spectrum should be checked in the index of Infra-red Peaks in Part 3. If the identity is suspected, the spectrum may be compared with that given in the monograph in Part 2.

Many theoretical reasons can be put forward to suggest why such a procedure would be useless (e.g. the product may contain more than one drug, or the contents may be insoluble in chloroform). However, in practice it is often a rapid, nondestructive method of identification. Even when the product does contain more than one drug, infrared spectrophotometers often have spectral subtraction routines which enable a pure spectrum to be obtained from a mixture.

For the majority of compounds, a mixture of 1 mg of drug with 150 mg of dry potassium bromide will produce a good spectrum. It is not too difficult to obtain a rough estimate of the amount of sample needed to achieve this concentration if the product has been partially identified by other means. However, when the identity is completely unknown, it may require several attempts to obtain a disk with the correct concentration. Table 8 may be used as a rough guide.

LOW DOSE PREPARATIONS

When the results of all the above analytical methods are negative, this information still may provide a useful clue to the possible identity of the sample. Homoeopathic and other low dose preparations should be considered.

If the unknown preparation contains less than 1 mg of active drug, the amount of substance extracted for each test may be too small to react under the test conditions. This is especially true if only one tablet has been analysed and the particular compound has few reactive functional groups. Tablets and capsules of modern high potency drugs usually have distinctive shapes, colours, or markings. If the tablet is small, white, and unmarked, it may be one of the established drugs with very low effective doses. A list of tablets and capsules which may contain 1 mg or less of active ingredient is given below.

Antihypertensives and drugs used in cardiac disorders: clonidine, deserpidine, digitoxin, digoxin,

glyceryl trinitrate, lanatosid C, reserpine, warfarin. Diuretics: cyclopenthiazide, polythiazide.

Ergot alkaloids and related drugs: dihydroergotamine, ergometrine, ergotamine, lysergide, methysergide.

Hypnotics, sedatives, and tranquillisers: benperidol, clonazepam, flunitrazepam, flupenthixol, haloperidol, lorazepam, lormetazepam, triazolam, trifluoperazine.

Steroids, hormones, and related compounds: beta-methasone, dexamethasone, dienolestrol, ethinyl-oestradiol, ethynodiol diacetate, fludrocortisone, liothyronine, lynoestrenol, mestranol, norethisterone, stilboestrol, thyroxine.

Miscellaneous drugs: atropine, colchicine, folic acid, hyoscine.

EXAMINATION OF SYRINGES

A syringe found at the scene of an incident or in the possession of the victim or suspect should always be examined by the toxicologist, even if it has been stated that it is clean or empty.

If the syringe contains a few drops of an aqueous solution, remove a portion with a small TLC-spotting pipette, and examine by the usual routine TLC systems. There is a high probability that a narcotic drug will be present, but barbiturates, amphetamine, or methylphenidate may also be abused using a syringe. Wash the syringe with 1 ml of water and use this solution for ultraviolet spectrophotometry in acid and at pH 10. If a drug is indicated, a pure sample of the substance should be examined in conjunction with the original undiluted aqueous solution.

If the syringe is dry, introduce one or two drops of methanol into the syringe, and proceed as described above.

The volumes of water used and any dilutions necessary for the ultraviolet examination must be noted in order to give a quantitative estimate of any drug present. Apart from the small amount used for TLC, the bulk of the extract is still available should analysis by gas chromatography or mass spectrometry be required. Direct solvent extraction can be applied to the extracts, and dilutions used for ultraviolet spectrophotometric analysis. This may also be necessary if the syringe is heavily blood-stained. It is important to remember that some of the drugs encountered in syringes are susceptible to alkaline

hydrolysis (e.g. diamorphine, methylphenidate, and barbiturates). Thus the addition of strong sodium hydroxide solution to the syringe should be avoided.

Metals and Anions

W. B. Yeoman

Samples

The samples usually available in suspected cases of non-fatal poisoning include stomach washings or vomit, blood, and urine. In postmortem cases, samples of stomach contents, blood, and urine should be obtained.

It is good practice to store all samples at -20° if analyses cannot be made immediately, and to retain all residues similarly, after reporting of results. It often becomes necessary to carry out further analyses on the samples or to submit them for validation of the findings by another laboratory. However, the samples must be allowed to return to room temperature gradually as the application of direct heat or even placing them in a low-temperature water-bath may result in the loss of unstable or volatile components.

Stomach Contents

Vomit or stomach contents aspirated before any wash-out procedures are the most suitable samples for analysis. Any unusual odours, the presence of food residues, or of 'altered' blood ('coffee grounds'), and the presence of any other foreign material should be noted. Both stomach contents and vomit are mucoid and frequently viscid and require nitration before further examination. Normal filtration of the sample may be difficult, a more satisfactory method is to force the sample through a 2-cm layer of cotton wool held in the barrel of a syringe. Stomach contents obtained at autopsy can be treated similarly. Alternatively, prepare a filterable slurry by adding water, mixing thoroughly, and filtering through a coarse grade filter paper. If the filtrate is too turbid or the slurry will not filter, add a suitable volume of a 10% solution of sodium carbonate, heat with continual stirring, and filter.

Although stomach contents are usually concentrated enough to allow direct analysis, stomach washings may be too dilute to yield meaningful results. Such a sample may be concentrated by distillation or by dialysis procedures, but this often leads to the loss of certain anions, such as hypochlorite, sulphide, and sulphite.

Isolation of Toxic Anions by Dialysis. Dialysis in cellophane bags or Visking tubing frequently succeeds where filtration procedures fail. However, it is more time consuming and may give low yields for borate, chlorate, and oxalate even after dialysis for 16 hours. It is rarely necessary for samples of food or drink. The dialyser should be as flat as possible. The thinner the layer in the inner container, and the larger the volume of water in the outer vessel, the more rapid the diffusion. Prepare a slurry of about 25 g of the gastric or intestinal contents, place it in the inner container, add 250 ml of water in the outer vessel, and dialyse for at least 2 hours. Carefully evaporate the dialysate (the contents of the outer vessel) to dryness in a platinum dish and dissolve the residue in a little water.

Isolation of Toxic Anions by Protein Precipitation. Prepare a slurry of the sample, coagulate the proteins with ammonium sulphate, filter, precipitate ammonium sulphate remaining in the filtrate with methanol, and evaporate the supernatant liquid (F. Rieders and F. J. Frere, *J. forens. Sci.*, 1963, 5, 46-53).

Blood

Venous blood (30 ml) should be obtained in all cases of suspected poisoning; a 5-ml portion of the sample should have an anticoagulant added to it. Heparinised sample containers should be avoided as the heparin may contain trace elements related to its animal source. If such a container is used, then a duplicate blank container should also be subjected to the assay to take account of possible contamination. In assays for lead and cadmium, either disodium or dipotassium edetate is the preferred anticoagulant.

Blood obtained at autopsy may be grossly contaminated by other fluids released during the autopsy procedure. A blood sample should therefore be obtained from a major artery or vein, e.g. the femoral artery. However, even these samples are likely to be highly haemolysed and give a poor yield of serum. It is therefore useful to perform some

simple digestion procedure, such as the enzyme digestion method for tissues (see p. 44), before analysis. If this approach is used, then the subsequent analysis performed on the sample must be repeated on a reagent blank. It is not unknown for a reagent blank to yield high concentrations of the analyte.

Low temperature ashing techniques for the assay of cations, using mixed reactive gases at low pressure (1 Torr) have been reported (F. G. Carter and W. B. Yeoman, *Analyst, Lond.*, 1980, 105, 295-297; H. T. Delves, *Prog. analyt. Atom. Spectres.*, 1981, 4-48).

Urine

The largest possible volume of urine should be submitted to the laboratory soon after the incident. To avoid the possibility of contamination, preservatives should not be added to the sample. The total volume should be measured immediately after receipt. A 20-ml portion of the sample should be stored at -20° for future reference.

Metals

The analysis of trace metals in biological fluids has been carried out for many years. An increased interest in environmental pollution, together with health-monitoring of individual workers has resulted in the rapid development of both sensitive instruments and sensitive techniques.

Atomic absorption spectrophotometry (AAS) is one of the most widely used methods. Either flame atomisation or electrothermal atomisation (ETA) using the graphite furnace is employed. Some useful references are given in the Bibliography.

The control systems in each atomic absorption instrument will have individual settings, and in all cases the manufacturer's instructions should be followed. Whichever instrument is used, a facility for background correction is mandatory in order to compensate for interference from the complex biological medium. However, background correction does have limitations when wavelengths below 300 nm are used.

Another approach to trace metal analysis has been the development of anodic stripping voltammetry (ASV), a derivative of classical polarography. An advantage of the method is that it requires relatively small volumes of blood. The need to subject samples to digestion procedures prior to ASV poses some difficulty, although digestants are available commercially. The advent of inductively coupled plasma/atomic emission spectroscopy (ICP/AES) which uses an argon

plasma as a heat source enables temperatures of up to 10000° to be attained and is potentially capable of enhanced sensitivity. Present practice, however, suggests that for many elements the ICP/AES may not offer superior sensitivity over conventional atomic absorption spectrophotometry.

Interference from endogenous biological materials in the sample poses problems with all these techniques and many workers routinely use preliminary digestion procedures. However, such an approach is not expedient in an emergency situation and generally, the simplest preparative steps yield the best results.

In the analytical methods which follow, the water used for making solutions should be double-distilled, and high-purity grade acids which are low in trace metals should be used. It is advisable to carry out all assays in duplicate. Dilute standard solutions should be freshly prepared.

Screening for Metals by Atomic Emission Spectroscopy

E. C. Blacklock and P.A. Sadler, *Clinica chim. Acta*, 1981, 713, 87-94.

A method which can be used as a screen for all heavy metals has not yet been devised. However, the following method will detect antimony, arsenic, bismuth, cadmium, lead, mercury, and thallium. Certain metals do not form complexes, e.g. barium and chromium, and these may be detected in trace amounts by direct application to the Lithium Fluoride-Graphite Mixture.

Reagents. Complexing Agent. Dissolve 10 g of ammonium pyrrolidine dithiocarbamate, 10 g of sodium diethyldithiocarbamate, and 10 g of potassium sodium tartrate in sufficient water to produce 1000 ml.

Lithium Fluoride-Graphite Mixture. Dry lithium fluoride at 250° for 1 hour, cool, and grind 1 part with 9 parts of non-pelletable graphite powder for 5 minutes.

Method. Liquid samples such as urine, spirits, beer, and lemonade can be assayed without prior extraction. Samples of food, stomach contents, or blood must be extracted as described below.

To 1 g of food or stomach contents or 1 ml of blood in a screw-capped test-tube add 1 ml of *nitric acid* and allow to stand overnight. Centrifuge at 3000 rpm for 15 minutes and to 1 ml of the supernatant liquid from the sample tube add sufficient water

to produce 10 ml. Adjust the aqueous solution to pH 4, transfer to a glass separating funnel, add 1 ml of the Complexing Agent and 4 ml of chloroform, and shake vigorously for 2 minutes; allow to separate and collect the chloroform layer in a glass vial. Repeat the extraction with a further 2 ml of chloroform and combine the chloroform extracts. Repeat the procedure using 1 ml of water (blank). Add the combined chloroform extracts (or 2 ml of a liquid sample) to 50 mg of the Lithium Fluoride-Graphite Mixture and evaporate by means of an infra-red lamp. Cool the mixture and tamp it into an anode cup for emission spectroscopy. Burn in a DC arc at 15 A, using a 3 mm rod as the counter electrode, using the following (or similar) conditions: Spectrograph—Hilger and Watt 3 metre grating; plate mask—2 mm; slit width—0.015 mm; analytical gap—6 mm; electrode mask gap—6 mm; exposure time—20 s; current—15 A; top electrode (negative)—Ringsdorff 3 mm graphite rod; bottom electrode (positive)—Ringsdorff RW0078 anode cup; charge weight—20 mg \pm 1 mg; photographic plate—Kodak Spectrum Analysis No. 1 (SA1); wavelength range—200 to 350 nm.

The method may be used in a semi-quantitative manner by visually comparing the sample plate against plates prepared with known concentrations of metals. The identity of any metal found in abnormal amounts should be confirmed by specific methods described later.

Reinsch Test

To 15 ml of the sample of body fluid or homogenised tissue extract, add 3 ml of *hydrochloric acid*, and immerse in the liquid a 5 mm x 10 mm copper strip or a spiral of copper wire formed by winding the wire around a glass rod ten times; heat gently for 2 hours. Remove the metal, wash gently with water and examine the surface.

A silver deposit indicates the presence of mercury; a shiny black deposit which is insoluble in *potassium cyanide solution* is given by bismuth; a dull black deposit which is soluble in *potassium cyanide solution* indicates the presence of arsenic; a purple deposit which is insoluble in *potassium cyanide solution* is given by antimony. Dark deposits may indicate selenium or tellurium, whereas a speckled discoloration is given by high concentrations of sulphur.

The test is sensitive to approximately 0.5 $\mu\text{g/ml}$ of arsenic, 10 $\mu\text{g/ml}$ of antimony and bismuth, and 2.5 $\mu\text{g/ml}$ of mercury.

Arsenic

Two methods are described below. A colorimetric method which is applicable to blood, and an atomic absorption spectrophotometric method which is applicable to urine. Both methods employ an arsine generating vessel. A large volume of blood (up to 50 ml) or urine (25 ml or more) may be required because concentrations of arsenic in the body may be near the detection limits of the assays.

COLORIMETRIC ASSAY FOR ARSENIC IN BLOOD

Standard Arsenic Solutions. Dissolve 2.4196 g of arsenic trichloride in sufficient M hydrochloric acid to produce 1000 ml. This solution contains 1 mg of As in 1 ml. Serially dilute the solution with water to produce solutions containing 0.5, 2.0, 5.0, and 10.0 μg of As in 1 ml.

Reagents. Silver DDC Solution. A 0.5% solution of silver diethyldithiocarbamate in pyridine. This reagent should be stored in amber bottles.

Stannous Chloride Reagent (40%). Dissolve 40 g of stannous chloride dihydrate in sufficient *hydrochloric acid* to produce 100 ml.

Digestion Mixture. To 3 volumes of *nitric acid* add 1 volume of *sulphuric acid* and 1 volume of *perchloric acid*.

Method. In cases of suspected arsenic poisoning, 5 ml of blood should be used; a larger volume may be required from unexposed subjects.

Place 5 ml of the blood sample in a 125-ml flask, add 5 ml of the Digestion Mixture, heat, gently at first, then at about 150°. When the solution boils and begins to char, add 2 ml of *nitric acid*; continue to add 1-ml quantities of *nitric acid* and a few drops of *perchloric acid* until a clear straw-coloured solution is obtained. Maintain the temperature until white fumes of sulphur trioxide are evolved and the solution is free from nitric acid. Cool, transfer quantitatively to a 10-ml volumetric flask, and dilute to volume with water.

Transfer 3 ml of the digested sample to the arsine generating vessel, add sufficient water to produce 35 ml, and then add 5 ml of *hydrochloric acid*, 2 ml of a 15% solution of potassium iodide, and 0.5 ml of Stannous Chloride Reagent (40%); swirl the solution, and allow to stand for 15 minutes. Insert a pad of glass wool moistened with *lead acetate solution* into the lower tube of the generating vessel. Introduce 3 ml of the Silver DDC Solution into the absorber tube, and 3 g of granulated zinc into the flask, and immediately assemble the two parts of the apparatus. Allow the evolution of arsine to continue for 1 hour. Transfer the Silver DDC

Solution from the absorber tube to a 1-cm cell, and record the absorbance at 540 nm, using in the reference cell a blank prepared by treating 5 ml of water in the same manner.

Repeat the procedure using 5 ml of each of the diluted standard solutions. Plot the absorbance of each standard solution against the concentration of arsenic, and read off the concentration in the sample.

ATOMIC ABSORPTION ASSAY FOR ARSENIC IN URINE
In this method, the arsine generator is suitably connected to the atomic absorption spectrophotometer.

Standard Arsenic Solutions. Prepare diluted standard solutions as described in the colorimetric assay, above.

Reagent. Stannous Chloride Reagent (20%). Dissolve 20 g of stannous chloride dihydrate in sufficient *hydrochloric acid* to produce 100 ml.

Method. To 25 ml of the urine sample, add 1 ml of a 20% solution of potassium iodide and 0.5 ml of Stannous Chloride Reagent (20%), mix, and allow to stand for 10 minutes. Isolate the arsine generator from the spectrophotometer, and introduce into the vessel 10 ml of the sample solution; add 0.5 g of granulated zinc and 1 ml of *hydrochloric acid*, immediately assemble the two parts of the generator, and stir with a magnetic stirrer for 2 minutes. Connect the arsine generator to the spectrophotometer and record the absorbance at 193.7 nm. Repeat the procedure using 25 ml of each of the diluted standard solutions and 25 ml of water (blank).

Plot the absorbance of each standard solution against the concentration of arsenic, and read off the concentration in the sample. The calibration curve is non-linear.

INTERPRETATION

Arsenic is distributed into all human tissues and fluids.

The concentration of arsenic in urine from unexposed subjects is less than 0.05 µg/ml. In cases of chronic poisoning, values between 0.05 and 5 µg/ml may be found. Acute poisoning is usually associated with values in excess of 1 µg/ml and may reach 20 µg/ml.

Arsenic is metabolised to monomethylarsonic acid and dimethylarsinic acid. Individuals exposed to arsenic, such as glass workers, may have a total arsenic concentration in the urine of up to 0.07 µg/ml, more than 50% of it appearing as

dimethylarsinic acid. High excretion of arsenic is also seen in consumers of seafood such as crab meat. Blood concentrations in unexposed subjects are usually in the range 0.001 to 0.025 µg/ml. Smokers may have slightly higher concentrations.

Cadmium

H. T. Delves and J. Woodward, *Atomic Spectroscopy*, 1981, 2, 65-67.

The following atomic absorption spectrophotometric technique is applicable to blood, and involves atomisation in a graphite furnace assembly. Blood samples should be anticoagulated with dipotassium edetate. If heparin is used, a blank containing heparin of the same batch should be carried through the preparative and assay procedures.

Standard Cadmium Solutions. Dissolve 2.7442 g of cadmium nitrate [$\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$] in sufficient M nitric acid to produce 1000 ml. This solution contains 1 mg of Cd in 1 ml. Serially dilute the solution with a 0.05% solution of *nitric acid* to produce solutions containing 0.0005, 0.001, 0.002, 0.004, 0.006, 0.008, and 0.01 µg/ml.

Method. To 100 µl of the sample of whole blood add 100 µl of a 0.05% solution of *nitric acid* and 100 µl of a 1% solution of ammonium dihydrogen phosphate, and mix thoroughly. Introduce 20 µl of the mixture into the graphite furnace, dry, ash, atomise, and record the absorbance at 228.8 nm.

Repeat the procedure using, in place of the sample, solutions prepared by adding 100 µl of each of the diluted standard solutions to 100 µl quantities of pooled normal blood.

Plot the absorbance of each standard solution against the concentration of cadmium, reduce the intercept to zero by drawing a parallel line through the origin, and read off the concentration in the sample. The calibration curve should be linear in the range 0 to 0.01 µg/ml.

INTERPRETATION

Blood-cadmium concentrations in non-smokers are less than 0.0025 µg/ml whereas smokers may exhibit concentrations of up to 0.0065 µg/ml; 50 to 70% of the cadmium is present in erythrocytes. Symptoms of cadmium toxicity appear at blood concentrations of 0.015 µg/ml or more. Concentrations in the urine, although variable, may be of a similar order to those found in blood.

Chromium

The following atomic absorption spectrophotometric technique is applicable to urine, and involves

atomisation in a graphite furnace assembly. The method of standard additions is used. Contamination from stainless steel needles should be avoided. The use of polystyrene test-tubes is recommended. This method may be modified to determine chromium in blood, but the assay conditions are much more critical.

Note. In an emergency, the sample of urine may be aspirated directly into a conventional air-acetylene flame and its absorbance at 357.9 nm compared with urine from an unexposed subject. *Standard Chromium Solutions.* Dissolve 7.6958 g of chromic nitrate [$\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$] in sufficient M nitric acid to produce 1000 ml. This solution contains 1 mg of Cr in 1 ml. Serially dilute the solution with 0.01 M nitric acid to produce solutions containing 0.01, 0.02, 0.03, 0.04, and 0.05 μg of Cr in 1 ml.

Method. To 10 ml of the urine sample add 0.1 ml of nitric acid and allow to stand for 1 hour. Transfer three 1-ml portions of the solution to separate test-tubes and to two of them add, respectively, 1 ml of standard solutions containing 0.02 and 0.05 $\mu\text{g}/\text{ml}$ of Cr; to the third tube add 1 ml of 0.01 M nitric acid. Introduce 5 μl of each solution into the graphite furnace, dry, ash, atomise, and record the absorbance at 357.9 nm. Record the absorbance of each of the diluted standard solutions in a similar manner. Plot the absorbance of each standard solution against the concentration of chromium, read off the concentration in the three sample tubes, and calculate the concentration in the sample. The calibration curve should be linear at least in the range 0 to 0.03 $\mu\text{g}/\text{ml}$.

INTERPRETATION

The concentration of chromium in urine samples from unexposed subjects is usually in the range 0.002 to 0.04 $\mu\text{g}/\text{ml}$. Whole blood concentrations of chromium are generally between 0.001 and 0.005 $\mu\text{g}/\text{ml}$.

Copper

The following colorimetric and atomic absorption spectrophotometric methods are applicable to serum. The atomic absorption method uses a conventional air-acetylene flame atomiser.

COLORIMETRIC ASSAY FOR COPPER IN SERUM

Standard Copper Solutions. Dissolve 1.000g of copper foil in the minimum volume of a 50% solution of nitric acid, and add sufficient of a 1% solution of nitric acid to produce 1000 ml. This solution contains 1 mg of Cu in 1 ml. Serially dilute the solution with water to produce solutions containing 0.5, 1.0, 1.5, and 2.0 μg of Cu in 1 ml.

Reagent. Oxalyl Dihydrazide Reagent. To 12 ml of strong ammonia solution add 8 ml of a saturated solution of oxalyl dihydrazide, 20 ml of a 40% solution of acetaldehyde, and 20 ml of water. *Method.* To 1 ml of the serum sample in a plastic centrifuge tube add 0.7 ml of 2M hydrochloric acid, mix, and allow to stand for 15 minutes; add 1 ml of a 20% solution of trichloroacetic acid, mix thoroughly, allow to stand for a further 15 minutes, and centrifuge. Transfer 2 ml of the supernatant liquid to a test-tube, add 3 ml of Oxalyl Dihydrazide Reagent, mix, and allow to stand for 20 minutes. Record the absorbance of the solution at 542 nm, using in the reference cell a blank prepared by treating 1 ml of water in the same manner. Repeat the procedure using the diluted standard solutions.

Plot the absorbance of each standard solution against the concentration of copper, and read off the concentration in the sample. The calibration curve should be linear for concentrations in the range 0 to 2 $\mu\text{g}/\text{ml}$.

ATOMIC ABSORPTION ASSAY FOR COPPER IN SERUM

Standard Copper Solutions. Prepare a solution of copper containing 1 mg in 1 ml as described in the colorimetric method, above. Serially dilute the solution with sodium chloride-potassium chloride solution to produce solutions containing 0.5, 1.0, 1.5, 2.0, and 2.5 μg of Cu in 1ml.

Method. Dilute 1 ml of the serum sample with sufficient of a 6% solution of butan-1-ol to produce 10 ml, mix, aspirate into an oxidising (blue) flame, and record the absorbance at 324.7 nm. Repeat the procedure with 1 ml of each of the diluted standard solutions, and with 1 ml of sodium chloride-potassium chloride solution (blank). Plot the absorbance of each standard solution against the concentration of copper, and read off the concentration in the sample. The calibration curve may be non-linear.

INTERPRETATION

The concentration of copper in normal serum samples is in the range 0.7 to 1.6 $\mu\text{g}/\text{ml}$. Hormone levels may affect the concentration of copper, and women using oestrogenic oral contraceptives may show concentrations as high as 3 $\mu\text{g}/\text{ml}$. Significantly lower serum concentrations are found in Wilson's disease (below 0.7 $\mu\text{g}/\text{ml}$). In cases of copper poisoning, concentrations in excess 3 $\mu\text{g}/\text{ml}$ have been reported.

Gold

The following atomic absorption spectrophotome-

tric technique is applicable to serum, and uses a conventional air-acetylene flame atomiser.

Standard Gold Solutions. Prepare a solution containing 1 mg of Au in 1 ml. Serially dilute this solution with *sodium chloride-potassium chloride solution* to produce solutions containing 0.5, 1.0, 1.5, 2.0, and 2.5 µg of Au in 1 ml.

Method. Dilute 1 ml of the serum with sufficient of a 6% solution of butan-1-ol to produce 4 ml, mix, aspirate into an oxidising (blue) flame, and record the absorbance at 242.8 nm.

Repeat the procedure with 1 ml of each of the diluted standard solutions, and with 1 ml of *sodium chloride-potassium chloride solution* (blank). Plot the absorbance of each standard solution against the concentration of gold, and read off the concentration in the sample. The calibration curve should be linear in the range 0.5 to 2.5 µg/ml.

INTERPRETATION

Trace amounts of gold present in serum from unexposed subjects may not be detected by this method. There appears to be little agreement regarding the interpretation of serum-gold concentrations, and it is difficult to correlate serum concentrations with dose. Following a dose of 50 mg of sodium aurothiomalate, serum-gold concentrations of 1.5 to 2 µg/ml have been obtained, whereas values of up to 15 µg/ml following an overdose of 500 mg have been reported. Gold appears to cross the placental barrier and has been detected in foetal kidney and liver. Excretion in the urine is extremely slow and the presence of gold in tissues has been demonstrated 1 year after a single dose.

Iron

The following atomic absorption spectrophotometric method is applicable to serum and uses a conventional air-acetylene flame atomiser.

Note. In emergencies, especially involving young children, the serum sample may be aspirated directly into the flame to give an indication of intoxication. A screening test for ferrous and ferric iron is given on p. 5. Commercial kits for the assay of iron in serum are available (see Reagent Appendix).

The assay of a urine sample in the presence of a chelating agent such as desferrioxamine involves elaborate sample preparation to hydrolyse the chelate, and electrothermal atomisation.

Standard Iron Solutions. Dissolve 0.484 g of ferric chloride hexahydrate in sufficient M hydrochloric acid to produce 100 ml. This solution contains 1 mg of Fe in 1 ml. Serially dilute the solution with *sodium chloride-potassium chloride solution* to produce solutions containing 0.5, 1.0, 1.5, 2.0, and 2.5 µg of Fe in 1 ml.

Reagent. Trichloroacetic Acid-Mercaptoacetic Acid Reagent. Dissolve 100 g of trichloroacetic acid in 500 ml of water, add 30 ml of mercaptoacetic acid and 166 ml of *hydrochloric acid*, allow the mixture to cool to room temperature and dilute to 1000 ml with water. The reagent should be stored in an amber bottle.

Method. To 2 ml of the serum sample add 2 ml of Trichloroacetic Acid-Mercaptoacetic Acid Reagent, mix thoroughly, allow to stand for 5 minutes, and centrifuge at 1700 rpm for at least 10 minutes. Aspirate the supernatant liquid into an oxidising (blue) flame, and record the absorbance at 248.3 nm.

Mix 25 ml of each of the diluted standard solutions and 25 ml of *sodium chloride-potassium chloride solution* with 25 ml of Trichloroacetic Acid-Mercaptoacetic Acid Reagent. Aspirate these solutions into the flame as for the sample.

Plot the absorbance of each standard solution against the concentration of iron, and read off the concentration in the sample.

INTERPRETATION

The concentration of iron in the serum of normal subjects is in the range 0.8 to 1.6 µg/ml. Iron is concentrated in the erythrocytes and whole blood concentrations in healthy subjects are in the range 380 to 560 µg/ml for females, and 450 to 625 µg/ml for males. The accidental poisoning of children with iron preparations is common and serum concentrations greater than about 3 µg/ml indicate the need for immediate therapy. Serum concentrations of up to about 25 µg/ml have been reported in intoxicated children, and up to about 50 µg/ml in cases of fatal poisoning.

Lead

Numerous procedures for the determination of lead in blood by atomic absorption spectrophotometry have been reported. The first method described here uses a nickel cup to contain the sample, a conventional air-acetylene flame atomiser, and a

nickel absorption tube. The second method uses a graphite furnace assembly. Both methods are applicable to whole blood.

FLAME ATOMISATION ASSAY FOR LEAD IN BLOOD

H. T. Delves, *Analyst, Lond.*, 1970, 95, 431-438. *Standard Lead Solutions.* Dissolve 0.16g of lead nitrate $[\text{Pb}(\text{NO}_3)_2]$ in sufficient 0.1M nitric acid to produce 100 ml. This solution contains 1 mg of Pb in 1 ml. Serially dilute the solution with water to produce solutions containing 0.1, 0.2, 0.4, 0.6, 0.8, and 1.0 μg of Pb in 1 ml.

Method. The blood sample, and a quantity of pooled normal blood to be used for preparing the standards, should be agitated for at least 30 minutes immediately before transferring to the vessel for atomisation.

Transfer 10 μl of the blood sample to a 10x5 mm nickel crucible (Delves cup), add 10 μl of water, and heat at 150° for 1 minute or until sputtering occurs. Add 20 μl of *strong hydrogen peroxide solution*, and evaporate to dryness at 150°. Place the cup in the air-acetylene flame and under the nickel absorption tube, and record the absorbance at 217 nm. The correct positioning of the cup is crucial. Repeat the procedure using a series of nickel crucibles containing, individually, 10 μl of the pooled normal blood and 10 μl of each diluted standard solution.

Plot the absorbance of each standard solution against the concentration of lead, reduce the intercept to zero by drawing a parallel line through the origin, and read off the concentration in the sample.

GRAPHITE FURNACE ASSAY FOR LEAD IN BLOOD

M. Stoeppler *et al.*, *Analyst, Lond.*, 1978, 103, 714-722.

Standard Lead Solutions. Prepare diluted solutions of lead as described in the flame atomisation method, above.

Method. The blood sample, and a quantity of pooled normal blood to be used for preparing the standards, should be agitated for at least 30 minutes immediately before transferring to the vessel for atomisation.

Transfer 100 μl of the blood sample to a polystyrene test-tube, add 150 μl of water and 150 μl of 2M nitric acid, mix vigorously for 30 seconds, centrifuge, and transfer the supernatant liquid into a 1-ml polyolefin cup. Introduce 10 μl of this solution into the graphite furnace, dry, ash, atomise, and record the absorbance at 217 nm.

Repeat the procedure using a series of polystyrene test-tubes containing, individually, 100 μl of the pooled normal blood and 150 μl of each of the diluted standard solutions.

Plot the absorbance of each standard solution against the concentration of lead, reduce the intercept to zero by drawing a parallel line through the origin, and read off the concentration in the sample.

interpretation

About 95% of the lead content of blood is in erythrocytes. The distribution of blood-lead within the normal population is skewed. The usual range of blood concentrations is between 0.06 and 0.35 $\mu\text{g}/\text{ml}$ with a median value of 0.13 $\mu\text{g}/\text{ml}$. Lead concentrations in adult females are between 0.02 and 0.03 $\mu\text{g}/\text{ml}$ lower than those in males of the same age groups. Concentrations in excess of 0.3 $\mu\text{g}/\text{ml}$ in children should be investigated further. Exposed subjects may have concentrations between 0.36 and 0.8 $\mu\text{g}/\text{ml}$ but be free from symptoms of intoxication. Values of 0.8 to 1.2 $\mu\text{g}/\text{ml}$ are associated with mild symptoms and such concentrations in children may cause 'lead encephalopathy'. Concentrations above 1.2 $\mu\text{g}/\text{ml}$ are usually associated with severe symptoms.

Lithium

The following method employs atomic emission spectrophotometry (flame photometry), and is applicable to serum.

Standard Lithium Solutions. Dissolve 4.3516g of lithium chloride monohydrate in sufficient 0.1M hydrochloric acid to produce 100 ml. This solution contains 5 mg of Li in 1 ml. Serially dilute the solution with *sodium chloride-potassium chloride solution* to produce solutions containing 5.0, 10.0, 15.0, 20.0, and 25.0 μg of Li in 1 ml.

Method. Dilute 1 ml of the serum sample to 50 ml with water, aspirate into an air-acetylene flame in a flame photometer, and record the emission intensity at 670.8 nm.

Repeat the procedure with 1-ml portions of the diluted standard solutions, and with 1 ml of *sodium chloride-potassium chloride solution* (blank). Plot the emission intensity of each standard solution against the concentration of lithium, and read off the concentration in the sample.

INTERPRETATION

Concentrations of lithium in normal serum are less than 0.5 $\mu\text{g}/\text{ml}$. For details of therapeutic and toxic

concentrations of lithium, see the monograph on Lithium Carbonate.

Mercury

K. C. Thompson and G. D. Reynolds, *Analyst, Land.*, 1971, 96, 771-775.

Flame atomisation is not necessary for the atomic absorption spectrophotometry of mercury. The cold vapour technique described here employs a reduction vessel (which may be purchased) to produce mercury vapour; the vapour is led to a quartz absorption cell within the atomic absorption instrument. The method is applicable to inorganic and organic mercurial compounds in urine.

Standard Mercury Solutions. Dissolve 0.1353g of mercuric chloride in sufficient 0.1M hydrochloric acid to produce 100 ml. This solution contains 1 mg of Hg in 1 ml. Serially dilute the solution with water to produce solutions containing 0.05, 0.10, and 0.15 µg of Hg in 1 ml.

Reagents. Stannous Chloride Solution. A 5% solution of stannous chloride dihydrate in a 25% solution of *hydrochloric acid*.

Hydrogen Peroxide Solution (50 volume). *Strong hydrogen peroxide solution* diluted with an equal volume of water.

Method. Transfer 5 ml of the urine sample into a 35-ml stoppered tube, add 1 ml of *hydrochloric acid*, mix, and allow to cool; add 10 ml of a 5% solution of potassium permanganate, mix, stopper loosely, and allow to stand overnight. Remove the excess potassium permanganate by adding, dropwise, Hydrogen Peroxide Solution (50 volume). Transfer 0.5 ml of the Stannous Chloride Solution to the reduction vessel, turn on the magnetic stirrer and the argon gas flow, and record the baseline absorbance at 253.7 nm. Add 3 ml of the prepared sample, immediately close the reduction vessel, stir for exactly 2 minutes, and record the absorbance at 253.7 nm.

Repeat the procedure using 5 ml of each of the diluted standard solutions and 5 ml of water (blank). Plot the absorbance of each standard solution against the concentration of mercury, and read off the concentration in the sample. The calibration curve should be linear for concentrations in the range 0 to 0.15 µg/ml.

INTERPRETATION

Urinary concentrations of mercury found in normal subjects are usually less than 0.05 µg/ml, although concentrations up to 0.1 µg/ml may be occasionally

found. However, values up to 0.3 µg/ml are not considered to be clinically significant. Excessive consumption of fish may produce urinary concentrations between 0.2 and 0.35 µg/ml without symptoms of intoxication. Children suffering from acrodynia (Pink disease) display urinary concentrations up to 4 µg/ml. In general, concentrations greater than 0.3 µg/ml are considered to be indicative of exposure to mercury. Elemental mercury is poorly absorbed from the gastro-intestinal tract and is not considered toxic by this route. Mercury vapour is absorbed through the skin and lungs and may produce toxicity; personnel engaged in the manufacture of mercury thermometers may excrete up to 3 mg/day. High urinary excretion of mercury may also be observed occasionally in subjects who have persistently used mercurial ointments for psoriasis.

Mercuric chloride is highly toxic, and ingestion of 1 g may prove fatal. A postmortem urine sample with a mercury concentration greater than 0.1 µg/ml is highly indicative of mercury poisoning.

Thallium

The following atomic absorption spectrophotometric method is applicable to blood and urine, and uses a conventional air-acetylene flame atomiser. **Standard Thallium Solutions.** Dissolve 1.3034g of thallous nitrate ($TlNO_3$) in sufficient water to produce 1000 ml. This solution contains 1 mg of Tl in 1 ml. Serially dilute the solution with water to produce solutions containing 0.2, 0.5, 1.0, 2.0, and 4.0 µg of Tl in 1 ml.

Reagent. Sodium DDC Solution. A 1% solution of sodium diethyldithiocarbamate.

Method/or Blood. Transfer 5 ml of the anticoagulated blood sample to a screw-capped centrifuge tube, add 1 ml of the Sodium DDC Solution, and 1 ml of a non-ionic surfactant (such as a 5% solution of Triton X-100), mix thoroughly, and allow to stand for 10 minutes. Add 3 ml of isobutyl methyl ketone, shake thoroughly, and centrifuge. Aspirate the organic layer into an oxidising (blue) flame, and record the absorbance at 276.7 nm.

Repeat the procedure with 5 ml of each of the diluted standard solutions, and with 5 ml of water (blank). Plot the absorbance of each standard solution against the concentration of thallium, and read off the concentration in the sample. The calibration curve should be linear in the range 0 to 4 µg/ml.

Method for Urine. The method is the same as that given for blood, above, except that the pH of the

sample and of the standard solutions should be adjusted to 7 to 7.5 before addition of Sodium DDC Solution, and the non-ionic surfactant is omitted.

INTERPRETATION

Concentrations of thallium in the blood or urine of unexposed subjects are usually less than 0.01 µg/ml. Clinical symptoms of intoxication are associated with blood concentrations of about 0.1 µg/ml; values of 8 to 10 µg/ml have been reported. Urinary concentrations of up to 20 µg/ml may be seen in exposed subjects. Thallium salts are highly toxic and doses of about 12 mg/kg of a soluble salt may be fatal.

Zinc

The following atomic absorption spectrophotometric method is applicable to serum, and uses a conventional air-acetylene flame atomiser. Zinc is present in erythrocytes and assays of whole blood are difficult to calibrate.

Note. Laboratory reagents, glassware, and other apparatus are likely to be contaminated with zinc. The use of zinc-free polypropylene test-tubes is recommended.

Standard Zinc Solutions. Dissolve 2.0846 g of zinc chloride in sufficient M hydrochloric acid to produce 1000 ml. This solution contains 1 mg of Zn in 1 ml. Serially dilute the solution with *sodium chloride-potassium chloride solution* to produce solutions containing 0.5, 1.0, 1.5, 2.0, and 2.5 µg of Zn in 1 ml.

Method. Dilute 1 ml of the serum sample to 10 ml with a 6% solution of butan-1-ol and mix. Aspirate into an oxidising (blue) flame, and record the absorbance at 213.8 nm.

Repeat the procedure with 1 ml of each standard solution, and 1 ml of *sodium chloride-potassium chloride solution* (blank).

Plot the absorbance of each standard solution against the concentration of zinc, and read off the concentration in the sample.

INTERPRETATION

Normal serum concentrations of zinc are in the range 0.7 to 1.7 µg/ml. Zinc salts are considered to be poisonous, but there appears to be no consensus of opinion on the minimum lethal dose. However, fatalities have been recorded following a dose of as little as 10 g of zinc sulphate. A number of suicides have been attempted with eye lotions containing zinc salts. Zinc derived from galvanised pipes occurs as a contaminant of drinking water.

Anions

Most commonly-encountered anions may be found in biological fluids, albeit at low concentrations. Possible sources for excessive concentrations of some anions of toxicological significance are listed below. The list is by no means exhaustive.

<i>Anion</i>	<i>Possible source</i>
Borate	Eye-drops, eye lotions, depilatory agents, topical preparations such as boric acid ointments and powders, and water softeners
Bromide	Sedative medicines, photographic chemicals, and industrial fumigants
Chlorate	Throat gargles, toothpastes, fireworks, matches, and weed killers
Cyanide	Amygdalin, metal polishes, insecticides, and metallurgical processing (plating)
Fluoride	Dentifrices, toothpastes, insecticides, and rodenticides
Hypochlorite	Bleaching agents and disinfectants
Iodine/Iodide	Antiseptics
Nitrate	Anti-anginal vasodilators, antiseptics, fertilisers, preservatives, and explosives
Nitrite	Preserved meats, from nitrate metabolism, and explosives
Oxalate	Rhubarb leaves, bleaching agents, cleaning agents, ink erasers, metal polishes, and anti-rust agents
Phosphate	Laxatives, matches, anti-rust agents, and water softeners
Sulphate	Electrical storage batteries and in industrial processes (as sulphuric acid)
Sulphide	Depilatory agents, paints, and hydrogen sulphide gas
Thiocyanate	Sodium nitroprusside, amygdalin, and insecticides

Qualitative tests for anions may be performed on stomach washings, gastric contents, or vomit. Anions may be extracted from the sample by the methods described on p. 55, although extraction by dialysis may result in the loss of borate, chlorate, and oxalate ions. In an emergency, the quantitative tests described below may be modified to identify anions present in serum, plasma, or urine samples. Where a sample of the suspected poison is available, tests should be carried out on it alongside those on the biological sample. Where the manufacturer of the suspected product can be identified, either the company or a Poisons Information Centre should be contacted for details of the formulation of the product. A useful source for information on the ingredients of medicinal products and some products of toxicological significance is *Martindale, The Extra Pharmacopoeia*, 28th Edn, J. E. F. Reynolds (Ed.), London, The Pharmaceutical Press, 1982.

Screening for Anions

A good deal of information is obtainable by acidifying the samples with dilute mineral acids and observing the reaction, first at room temperature and then after gentle application of heat. Bicarbonates, carbonates, cyanides, hypochlorites, nitrates, and nitrites yield characteristic gases following such treatment. Care must be exercised when cyanide intoxication is suspected as hydrogen cyanide may be evolved.

Transfer to 2 test-tubes either 1-ml portions of filtered or clarified gastric contents, or 5-ml portions of stomach washings. To one tube add an equal volume of *silver nitrate solution*, observe the reaction and then add a 30% v/v solution of *nitric acid*. To the second tube add an equal volume of *barium chloride solution*, observe the reaction and then add a 30% solution of *nitric acid*.

INTERPRETATION

Result	Indication
A precipitate with silver nitrate solution which is insoluble in nitric acid; no reaction with barium chloride solution	Presence of bromide, chloride, cyanide, hypochlorite, iodide, or thiocyanate
A precipitate with silver nitrate solution which is soluble in nitric acid; no reaction with barium chloride solution	Presence of cyanates, sulphites, or boric, carbonic, iodic, oxalic, and nitrous acids
A precipitate with silver nitrate solution, and with barium chloride solution, soluble in nitric acid	Presence of silicates, thiosulphates, or arsenic, arsenious, chromic, or phosphoric acids
No precipitate with silver nitrate solution or with barium chloride solution	Presence of hydrochloric, nitric, or perchloric acids
No reaction with silver nitrate solution; precipitate with barium chloride solution which is insoluble in nitric acid	Presence of fluoride or sulphate. High concentrations of sulphates give a precipitate with silver nitrate

Tests for Specific Anions

The presence of a particular anion may be confirmed by qualitative tests performed on 5 ml of filtered gastric contents or 10 ml of stomach washings. Quantitative assays may then be performed if necessary.

Borate

COLOUR TESTS

1. Acidify a portion of the sample with *dilute hydrochloric acid*, and apply the solution to turmeric paper. A brown-red colour, which intensifies when the paper is dried indicates the presence of borate.

Moisten the paper with *dilute ammonia solution*; a green-black colour is produced. The test is sensitive to 20 µg/ml of borate.

2. Transfer a portion of the sample to an evaporating basin, add 1 ml of *sulphuric acid* and 3 ml of ethanol, and ignite. A green border around the flame indicates the presence of borate.

COLORIMETRIC ASSAY FOR BORATE IN SERUM

Standard Borate Solutions. Dissolve 0.210 g of boric acid in sufficient water to produce 100 ml. This solution contains 2 mg of BO_3^{3-} in 1 ml. Serially dilute this solution with pooled normal serum to produce solutions containing 20, 50, 100, and 200 µg of BO_3^{3-} in 1 ml.

Reagent. Carminic Acid Reagent. Dissolve 0.02 g of carminic acid in sufficient *sulphuric acid* to produce 100 ml.

Method. Transfer 1 ml of the serum sample, and 1 ml of pooled normal serum (blank) to separate 15-ml centrifuge tubes and carry out the following procedure on each tube. Add 5 ml of a 4% solution of ammonium sulphate, mix thoroughly, and heat in a boiling water-bath for 15 minutes. Centrifuge at 3500 rpm for 10 minutes, and transfer the supernatant liquid to a 10-ml volumetric flask. Wash the precipitate in the centrifuge tube by shaking with 2 ml of water, centrifuge, and add the supernatant liquid to the volumetric flask. Add sufficient water to the flask to produce 10 ml and mix. To 1 ml of this solution add 5 ml of *sulphuric acid*, mix thoroughly, add 5 ml of the Carminic Acid Reagent, mix thoroughly, and allow the colour to develop for 10 minutes. Record the absorbance of the solution obtained from the sample at 600 nm, using the solution obtained from the pooled normal serum in the reference cell.

Repeat the procedure with the diluted standard solutions.

Plot the absorbance of each of the standard solutions against the concentration of borate ion, and read off the concentration in the sample.

INTERPRETATION

The concentration of borate ion in normal serum is up to about 7 µg/ml; concentrations between 20 and 150 µg/ml are associated with toxicity. Concentrations from 200 to 1500 µg/ml have been reported in fatalities.

Bromide

COLOUR TESTS

1. To a portion of the sample add an equal volume of *silver nitrate solution*. A yellow precipitate which

is insoluble in a 30% v/v solution of *nitric acid* and slightly soluble in *dilute ammonia solution*, indicates the presence of bromides. 2. To a portion of the sample add 5 ml of *chlorine solution* and 3 ml of chloroform. A yellow colour which is extracted into the chloroform layer indicates the presence of bromide; iodides give a violet colour and chlorides do not react.

COLORIMETRIC ASSAY FOR BROMIDE IN SERUM

Standard Bromide Solutions. Dissolve 1.2877 g of sodium bromide in sufficient water to produce 500 ml. This solution contains 2 mg of Br in 1 ml. Serially dilute this solution with water to produce solutions containing 200, 400, 600, 800, 1200, and 1600 µg of Br in 1 ml.

Reagent. Chloroauric Acid Solution. Dissolve 0.5 g of chloroauric acid (gold chloride, $\text{HAuCl}_4 \cdot x\text{H}_2\text{O}$) in sufficient water to produce 100 ml.

Method. Transfer 2 ml of the serum sample, and 2 ml of water (blank) to separate centrifuge tubes and carry out the following procedure on each tube. Add 4 ml of a 20% solution of trichloroacetic acid, mix thoroughly, allow to stand for 15 minutes, and then centrifuge at 2000 rpm for 5 minutes. Transfer 4 ml of the supernatant liquid to another tube, add 1 ml of the Chloroauric Acid Solution, and record the absorbance of the solution obtained from the sample at 440 nm, using the blank solution in the reference cell.

Repeat the procedure with the diluted standard solutions.

Plot the absorbance of each of the standard solutions against the concentration of bromide ion, and read off the concentration in the sample.

INTERPRETATION

Bromide concentrations in normal serum are usually less than 10 µg/ml. Following therapeutic administration of bromides, concentrations of up to 80 µg/ml are attained. Toxicity is usually associated with concentrations above 500 µg/ml, although some individuals may show signs of intoxication at values as low as 300 µg/ml. Bromide has a plasma half-life of about 15 days.

Chlorate

COLOUR TESTS

1. Acidify a portion of the sample with *dilute sulphuric acid*, and add 1 ml of a 1% solution of indigo carmine. A deep blue colour is given by chlorates.

2. To 5 ml of vomit add 5 ml of a 20% solution of

trichloroacetic acid and filter. Divide the filtrate into two equal portions; to the first portion add 2 ml of aniline and 1 ml of M hydrochloric acid. A blue-green colour is given by chlorates. To the second portion, add 2 ml of a 1% solution of diphenylamine in *sulphuric acid*. A blue colour is given by chlorates. Ingestion of chlorate renders the blood brown due to the formation of methaemoglobin. To 1 ml of blood, add 2 drops of *potassium cyanide solution*. An immediate red colour confirms the presence of methaemoglobin; sulphaemoglobin does not give this colour.

INTERPRETATION

Serious and sometimes fatal poisoning occurs after the ingestion of 15 g or more of sodium or potassium chlorate.

Cyanide

COLOUR TESTS

Distil the sample into a 10% solution of sodium hydroxide, and carry out the following tests on the alkaline distillate.

1. Add a freshly prepared 10% solution of ferrous sulphate in freshly boiled and cooled water; a precipitate of ferrous hydroxide is formed. Add sufficient *dilute hydrochloric acid* to dissolve the precipitate; a blue colour (Prussian Blue) indicates the presence of cyanide.

This test is specific for cyanides and in an emergency can be performed directly on gastric contents without prior distillation.

2. Add *ammonium poly sulphide solution* and evaporate to dryness on a water-bath. To the residue add a few drops of *dilute hydrochloric acid*, filter, and to the filtrate add a few drops of *ferric chloride solution*. A deep red colour due to ferric thiocyanate indicates the presence of cyanide.

COLORIMETRIC ASSAY FOR CYANIDE IN SERUM OR WHOLE BLOOD

Cyanide may be lost or produced during storage of whole blood; samples should be stored at 4° and analysed as soon as possible. Cyanide concentrations may decrease significantly after death.

Standard Cyanide Solutions. Dissolve 0.025 g of potassium cyanide in sufficient water to produce 10 ml. This solution contains 1 mg of CN^- in 1 ml. Serially dilute this solution with normal blood or serum, as appropriate, taken from non-smokers, to produce solutions containing 0.5, 1.0, 2.0, and 5.0 µg of CN^- in 1 ml. The diluted solutions should be freshly prepared.

Reagents. Barbituric Acid and Pyridine Reagent. Dissolve 3 g of barbituric acid in 15 ml of pyridine in a 25-ml volumetric flask, slowly add 3 ml of *hydrochloric acid*, and dilute with sufficient water to produce 25 ml. The mixture may be warmed to effect solution.

Phosphate Solution. Dissolve 15.6g of sodium dihydrogen phosphate dihydrate in sufficient water to produce 100ml.

Method. To the outer compartments of two Conway microdiffusion cells add 0.5 ml of *dilute sulphuric acid*, and to the inner compartments add 0.5 ml of 0.1M sodium hydroxide. To the outer compartments add 0.5 ml of the serum or blood sample, and 0.5 ml of normal serum or whole blood (blank) respectively; immediately close the cells and carry out the following procedure on each cell. Gently agitate the cells, ensuring that the contents of the two compartments do not mix, and allow to stand for at least 2 hours. Transfer 0.1 ml of the solution from the inner compartment to a tube containing 1 ml of the Phosphate Solution, add 0.5 ml of a 0.25% solution of Chloramine-T, mix, allow to stand for 3 minutes, add 1.5 ml of the Barbituric Acid and Pyridine Reagent, mix, and allow to stand for 10 minutes. Record the absorbance of the solution obtained from the sample at 580 nm, using the blank solution in the reference cell.

Repeat the procedure with the diluted standard solutions.

Plot the absorbance of each of the standard solutions against the concentration of cyanide ion, and read off the concentration in the sample.

INTERPRETATION

Blood-cyanide concentrations of up to 0.02 µg/ml may be found in normal individuals who do not smoke; smokers may have concentrations of up to about 0.05 µg/ml. Acute toxicity is associated with blood concentrations of 0.5 µg/ml or more; such concentrations may be encountered during sodium nitroprusside therapy for hypertension. Concentrations above 1 µg/ml have been reported in fatalities. Cyanide is concentrated in the erythrocytes.

Fluoride

QUALITATIVE TESTS

1. To a portion of the sample add a 25% solution of calcium chloride. Fluorides give a white gelatinous precipitate which is insoluble in a 30% v/v solution of *acetic acid*, and slightly soluble in *dilute hydrochloric acid*.

2. Dry a portion of urine or vomit, and fuse with calcium hydroxide. Add 0.2 g of purified sand and transfer to a lead dish. Smear a film of soft paraffin on the reverse of a glass cover plate, and expose part of the glass by making an identifiable sign on the paraffin film. Add 5 ml of *sulphuric acid* to the dish, place the cover plate on it with the paraffin layer on the inside, and heat gently for 20 minutes. Remove the paraffin film from the cover plate. An etched mark on the plate, corresponding to the mark made, indicates the presence of fluoride.

ASSAY FOR FLUORIDE IN PLASMA OR URINE BY ION-SPECIFIC POTENTIOMETRY

Standard Fluoride Solutions. Dissolve 0.221 g of sodium fluoride, previously dried at 300° for 12 hours, in sufficient water to produce 1000 ml. This solution contains 100 µg of F⁻ in 1 ml. Serially dilute this solution with the Buffered Sodium Chloride Solution to produce solutions containing 0.01, 0.05, 0.10, and 0.20 µg of F⁻ in 1 ml. All standard fluoride solutions should be stored in polyethylene containers.

Reagent. Buffered Sodium Chloride Solution. Dissolve 6.4 g of sodium chloride, 13.6 g of sodium acetate, and 6 ml of *acetic acid* in sufficient water to produce 1000 ml. The solution should be stored in a polyethylene container.

Method. For plasma samples, dilute 1 volume with 1 volume of the Buffered Sodium Chloride Solution. For urine samples, dilute 1 volume with 9 volumes of the reagent. Insert the electrode of an ion-specific fluoride meter into the diluted sample and allow to equilibrate for 30 minutes. Record the ion potential of the solution.

Dilute 1 volume of each of the diluted standard solutions with 1 volume of the Buffered Sodium Chloride Solution, and record the ion potential of each solution.

Plot the ion potential of each standard solution against the concentration of fluoride ion, and derive the concentration in the sample.

INTERPRETATION

Plasma concentrations of fluoride are normally less than 0.2 µg/ml; urine concentrations are usually less than 1 µg/ml but up to 4 µg/ml is not considered harmful. Blood concentrations greater than

2.6 µg/ml have been reported in fatalities. Young children may ingest up to 0.5 g of fluoride by swallowing fluoride toothpaste. Stannous fluoride is a common ingredient so that a test for excess tin may aid interpretation.

Hypochlorite

COLOUR TESTS

1. Acidify a portion of the sample with *dilute hydrochloric acid*. Evolution of chlorine indicates the presence of hypochlorite; the solution may be yellow.
2. To a portion of the sample add *silver nitrate solution*. A white precipitate is given by hypochlorite.
3. Moisten *starch-iodide paper* with the sample. A blue colour is given by hypochlorite.
4. Filter a portion of the sample and add 2 drops of the filtrate to 1 ml of a 1 % solution of diphenylamine in *sulphuric acid*. An immediate blue colour is given by hypochlorite.

Iodide

COLOUR TESTS

1. To a portion of the sample add 5 ml of *chlorine solution* and 3 ml of chloroform. A violet colour in the chloroform layer indicates the presence of iodide.
2. To a portion of the sample add *silver nitrate solution* and an equal volume of a 30% v/v solution of *nitric acid*. A curdy yellow precipitate which is insoluble in *dilute ammonia solution* is given by iodides.

Nitrite

COLOUR TESTS

1. To 10 ml of gastric contents, stomach washings, or vomit, add 10 mg of diphenylamine sulphate and then carefully add 5 ml of *sulphuric acid* to form a separate layer. A blue ring at the interface is indicative of nitrites.
2. To 10 ml of the sample add 10 mg of brucine sulphate and carefully add 5 ml of *sulphuric acid* to form a separate layer. A red ring at the interface is given by nitrites.
3. To a portion of the sample, add 0.5 ml of a 10% solution of potassium iodide and 0.5 ml of *dilute hydrochloric acid*. Liberation of iodine which turns *starch mucilage* blue is indicative of nitrites. The presence of nitrites in blood renders it brown due to the formation of methaemoglobin. To 1 ml of blood add 2 drops of *potassium cyanide solution*. An immediate red colour confirms the presence of methaemoglobin.

COLORIMETRIC ASSAY FOR NITRITES IN URINE

The nitrite ion is rapidly eliminated from blood and it is best to assay urine in cases of suspected overdose. *Standard Nitrite Solutions*. Dissolve 1.5 g of sodium

nitrite in sufficient water to produce 1000 ml. This solution contains 1 mg of NO_2^- in 1 ml. Serially dilute this solution with water to produce solutions containing 10, 20, 50, and 100 μg of NO_2^- in 1 ml. *Reagents*. Naphthylamine Solution. Dissolve 0.48 g of 1-naphthylamine in sufficient of a 20% v/v solution of *hydrochloric acid* to produce 100 ml.

Sulphanilic Acid Solution. Dissolve 0.6 g of sulphanilic acid in sufficient of a 20% v/v solution of *hydrochloric acid* to produce 100 ml.

Method. Add 1 ml of the urine sample and 1 ml of water (blank) to two separate 50-ml volumetric flasks, and carry out the following procedure on each flask. Add 1 ml of the Sulphanilic Acid Solution, mix, and allow to stand for 10 minutes. Add 1 ml of the Naphthylamine Solution and 1 ml of a 16.4% solution of sodium acetate, dilute to 50 ml with water, mix, and allow to stand for 10 minutes. Record the absorbance of the solution obtained from the sample at 510 nm, using the blank solution in the reference cell. Repeat the procedure with each of the diluted standard solutions.

Plot the absorbance of the standard solutions against the concentration of nitrite ion, and read off the concentration in the sample. The calibration curve should be linear in the range 0 to 50 $\mu\text{g}/\text{ml}$.

INTERPRETATION

In reported cases of overdose, the blood and urine concentrations have been extremely variable. High concentrations may be found after heavy consumption of preserved meats. The concentration of methaemoglobin in the blood is an indication of the degree of toxicity.

Oxalate

COLOUR TESTS

Acidify the sample with *dilute hydrochloric acid*, add 3 ml of ethanol, and heat to precipitate the proteins. Extract the sample with 3 quantities of ether; combine the organic layers and evaporate to dryness. Dissolve the residue in 3 ml of water and carry out the following tests:

1. To 1 ml of the solution, add 2 drops of *dilute sulphuric acid* and 3 drops of a 1% solution of potassium permanganate. Disappearance of the violet colour is indicative of the presence of oxalate.
2. To 1 ml of the solution add 1 ml of *silver nitrate solution*. A white precipitate which is soluble in a 30% v/v solution of *nitric acid* is given by oxalates.
3. To 1 ml of the solution add 1 ml of a 25% solution

of calcium chloride. A precipitate which is soluble in a 30% v/v solution of *acetic acid* but insoluble in *dilute hydrochloric acid* is given by oxalates. A method for the determination of oxalate in serum by gas chromatography has been described by P. Nuret and M. Offner, *Clinica chim. Acta*, 1978, 82, 9-12.

INTERPRETATION

Trace amounts of oxalate in urine are not usually significant as oxalates are present in many plant foods; approximately 2 to 10 mg is excreted daily in the urine. Oxalate may also occur in urine as a result of poisoning with ethylene glycol.

Sulphide

COLOUR TEST

To a portion of the sample add 3 ml of *dilute sulphuric acid* and heat the solution. Hydrogen sulphide fumes which turn *lead acetate paper* black are given by sulphides.

COLORIMETRIC ASSAY FOR SULPHIDE IN BLOOD

Standard Sulphide Solutions. Prepare a solution of sodium sulphide to contain 1 mg of sulphide ion in 1 ml. Serially dilute this solution with pooled normal blood to produce solutions containing 0.5, 1.0, and 2.0 µg of sulphide ion in 1 ml.

Reagents. Acidic Ferric Chloride Solution. Dissolve 0.2 g of ferric chloride in sufficient *dilute hydrochloric acid* to produce 100 ml.

Dimethylphenylenediamine Solution. Dissolve 0.1 g of *NN*-dimethyl-*p*-phenylenediamine in sufficient of a 50% v/v solution of *hydrochloric acid* to produce 100 ml.

Method. To the outer compartments of two Conway microdiffusion cells add 4 ml of 0.5M sulphuric acid, and to the inner compartments add 3 ml of 0.1M sodium hydroxide. To the outer compartments add 4 ml of the blood sample and 4 ml of normal blood (blank), respectively; immediately close the cells and carry out the following procedure on each cell. Gently agitate the cells, ensuring that the contents of the two compartments do not mix, and allow to stand for at least 2 hours at 37°, or for 4 hours at room temperature. Transfer 2 ml of the solution from the inner compartment to a 15-ml centrifuge tube, add 2 ml of a mixture containing equal volumes of the Acidic Ferric Chloride Solution and the Dimethylphenylenediamine Solution, mix thoroughly, and allow to stand for 10 minutes. Record the absorbance of the solution obtained, from the sample at 670 nm, using the solution obtained from the blank in the reference cell.

Repeat the procedure with the diluted standard solutions.

Plot the absorbance of each of the standard solutions against the concentration of sulphide ion, and read off the concentration in the sample.

INTERPRETATION

Sulphide concentrations in the blood of unexposed subjects are usually less than 0.05 µg/ml. Fatalities have been associated with concentrations between 1 and 5 µg/ml which indicate ingestion of about 10 g of a soluble sulphide.

Sulphite

COLORIMETRIC ASSAY FOR SULPHITE IN URINE

Urine is the preferred sample but the method may also be used for stomach washings. *Standard Sulphite Solutions.* Dissolve 1.5746g of anhydrous sodium sulphite in sufficient water to produce 1000 ml. This solution contains 1 mg of SO_3^{2-} in 1 ml. Serially dilute this solution with water to produce solutions containing 0.5, 1.5, 3.0, 6.0, and 10.0 µg of SO_3^{2-} in 1 ml.

Reagents. Magenta Solution. Dissolve 0.02g of basic magenta (fuchsin, CI 42510) in sufficient M hydrochloric acid to produce 100 ml. This reagent should be protected from light. Formaldehyde Reagent. Dilute 1 ml of methanol-free *formaldehyde solution* to 1000 ml with water.

Method. To 50 µl of the sample add 1 ml of the Magenta Solution and 3 ml of Formaldehyde Reagent, and allow to stand for 5 minutes. At the same time, prepare a blank solution by adding 1 ml of Magenta Solution and 3 ml of water to 50 µl of the sample. Record the absorbance of the first solution at 570 nm, using the second solution in the reference cell.

Repeat the procedure for the diluted standard solutions.

Plot the absorbance of the standard solutions against the concentration of sulphite ion, and read off the concentration in the sample.

INTERPRETATION

The normal urinary concentration of sulphite ion is less than 6 µg/ml. The estimated lethal dose of sulphurous acid is 10 g.

Thiocyanate

COLOUR TEST

To a portion of the sample add 1 ml of *ferric chloride solution*. A deep red colour is given by thiocyanates.

This test may also be performed on serum or plasma after precipitation of the proteins.

COLORIMETRIC ASSAY FOR THIOCYANATE IN SERUM AND PLASMA

Standard Thiocyanate Solution. Dissolve 9.718 g of potassium thiocyanate in 100 ml of water and dilute with sufficient water to produce 1000ml. This solution contains 0.1 mmol of CNS^- in 1 ml. Its exact strength should be ascertained by titration with silver nitrate. Dilute 0.5 ml of this solution to 100 ml with water.

Reagent, Acidic Ferric Nitrate Solution. Dissolve 80 g of ferric nitrate nonahydrate in 250 ml of 2M nitric acid, dilute with sufficient water to produce 500 ml, and filter.

Method. To 0.5 ml of the sample add 4.5 ml of a 5% solution of trichloroacetic acid, allow to stand for 15 minutes, and centrifuge. Transfer 2 ml of the supernatant liquid, 2 ml of the diluted standard solution, and 2 ml of water (blank) to 3 separate tubes. Whilst excluding light, add 4 ml of the Acidic Ferric Nitrate Solution to each tube, mix, and record the absorbance of the sample and standard solutions at 460 nm, using the blank solution in the reference cell.

Calculate the concentration in the sample by comparison with the standard solution.

INTERPRETATION

Thiocyanate is a metabolite of cyanide and in addition to its toxicological significance, measurement of blood-thiocyanate concentrations aids in the verification of an individual's compliance with an anti-smoking programme. Plasma concentrations in non-smokers range from 0.1 to 4 $\mu\text{g/ml}$, whereas in smokers concentrations range from about 5 $\mu\text{g/ml}$ up to 20 $\mu\text{g/ml}$. Serum concentrations of up to about 200 $\mu\text{g/ml}$ have been recorded in fatalities.

Pesticides

R. R. Fysh and M. J. Whitehouse

Several hundred compounds are available for use as pesticides and there is a need for systematic screening methods for use in forensic or clinical toxicology laboratories. The methods should be sensitive, specific, and applicable to the examination of proprietary formulations, food and drink, or biological fluids. A number of such methods are described here, ranging from simple tests to a comprehensive scheme based on gas chromatography and combined gas chromatography-mass spectrometry (GC/GC-MS). The simple methods are particularly useful when a specific pesticide, or one of a group of pesticides, is implicated by the case history because of exhibits found at the 'scene' or from signs and symptoms shown by the victim. However, the GC/GC-MS method is likely to be the most successful approach when little or nothing is known about the suspect material and only limited quantities are available.

CLASSIFICATION OF INSECTICIDES AND HERBICIDES

The terms 'pesticide' and 'insecticide' are often confused or used interchangeably. This is incorrect since the word 'pesticide' is a general one which covers a wide variety of substances and may be applied to any substance which is used to destroy undesirable life forms. Pesticides therefore include insecticides, fungicides, herbicides, rodenticides, nematocides, molluscicides, and acaricides. Only insecticides and herbicides are dealt with here since the other pesticides are encountered only rarely in toxicology.

In the following classification, insecticides and herbicides are distinguished by chemical type. However, this classification is not unique since some may be used for both purposes. Combinations of herbicides or insecticides may be found in some commercial formulations.

The common names approved by the British Standards Institution (BSI) and the International Organization for Standardization (ISO) have been used throughout for convenience and brevity. The preferred names of the International Union of Pure

and Applied Chemistry (IUPAC) can be obtained from the Pesticide Manual (see Bibliography),

Insecticides

These may be classified into four chemical groups: *Chlorinated hydrocarbons* which include dicophane (DDT) and its analogues (e.g. dicofol and methoxychlor), hexachlorocyclohexane isomers (e.g. lindane), and bridged polycyclic chlorinated compounds (e.g. chlordane);

Organophosphorus insecticides which include phosphorodithioates (e.g. malathion), phosphorothionates (e.g. parathion), phosphorothioates (e.g. omethoate), and phosphates (e.g. mevinphos); *Carbamates* which are essentially *N*-methylcarbamates (e.g. carbaryl);

Alkaloidal insecticides which include natural and synthetic pyrethrins, rotenone, and nicotine.

Herbicides

These may be classified into at least eleven groups but the five most important groups are:

Chlorinated phenoxy acids, e.g. 2,4-dichlorophen-oxyacetic acid (2,4-D) and dichlorprop;

Substituted ureas, e.g. linuron and chlorbrpxp-uron; *Triazine herbicides*, e.g. simazine;

Uracilherbicides, e.g. bromacil;

Quaternary ammonium compounds, e.g. paraquat and diquat.

Table 1 (p. 81) gives an alphabetical list of over 200 compounds together with their uses and chemical classification.

Toxicity

Pesticides include such a diversity of chemical types that it is not surprising that their toxicity covers a very wide range. For example, as little as 100 mg of mevinphos or of nicotine may cause death, whereas 1.5 kg of the herbicide aminotriazole is unlikely to endanger human life. Even within a particular class of pesticide the lethal dose may vary considerably.

In Table 1 the pesticides have been classified arbitrarily into six groups according to their toxicity rating and these ratings are related to the estimated lethal dose. The majority of the ratings have been derived from determinations of median lethal doses (LD50) in small laboratory animals. They are intended to be a guide to their relative toxicities and should only be used in this manner.

Although certain pesticides may be considered to be only moderately or slightly toxic, the vehicle in which they are formulated (e.g. kerosene or toluene) may be more toxic and can be, in some cases, the main causative agent for the symptoms observed. For a more detailed discussion of the toxicities of pesticides, see the references in the Bibliography.

TECHNIQUES OF ANALYSIS

Available methods range from simple chemical tests to those which utilise instrumental techniques of varying degrees of sophistication. The ideal method should be specific, sensitive, of wide applicability, simple, and rapid, with results which can be easily interpreted. Unfortunately, no technique combines all these attributes and the analyst is advised to be aware of the limitations of a particular method.

Colour Tests

Although lacking in specificity and, in some cases sensitivity, these tests can be extremely valuable in indicating the class of compound. They may also be used as a quick confirmation of the constituents of a proprietary formulation. In order to ensure that false positives are not obtained and to check the reagents, a reference compound together with a blank solution should be carried through the same procedure as the sample.

Some colour tests for pesticides are described under Colour Tests, including Nitric-Sulphuric Acid (p. 143) for dicophane. Phosphorus Test (p. 144) for organophosphorus compounds. Sodium Dithionite (p. 144) for diquat and paraquat, and Sulphuric Acid-Fuming Sulphuric Acid (p. 146) for dieldrin, aldrin, and endrin.

In addition, many other tests described on pp. 129-147 may be used for pesticides, especially Aromaticity (Method 2), Diphenylamine Test, Fujiwara Test, Koppanyi-Zwicker Test, Liebermann's Test, Marquis Test, Methanolic Potassium Hydroxide, Palladium Chloride, Sodium Nitroprusside (Method 2), and Sulphuric Acid. Certain pesticides are included in the Tables of colours, where appropriate. A test for the presence of cholinesterase inhibitors

in blood is given on p. 6, and a method for the quantification of cholinesterase activity in serum is given on p. 23.

Spectroscopic Methods

Ultraviolet, infra-red, nuclear magnetic resonance, and mass spectrometry all find a role in the analysis of pesticides, but only ultraviolet and mass spectrometry are suitable for screening purposes. Infra-red and nuclear magnetic resonance require extensive clean-up procedures before they can be used and the sample requirement is not consistent with the concentrations usually available in toxicology cases. However, both these techniques are valuable in the differentiation of isomers.

ULTRAVIOLET SPECTROPHOTOMETRY

Pesticides in food, drink, and biological fluids may be detected by ultraviolet spectrophotometry, usually after a simple extraction procedure. However, care must be taken to ensure that there are no ultraviolet-absorbing co-extracted compounds which could interfere. The main drawback of the method is a lack of specificity, because the UV spectrum usually only indicates the group to which a particular pesticide belongs. In addition, those pesticides which lack a chromophore, e.g. chlorinated hydrocarbons, cannot be screened by this method. Nevertheless, UV data can be useful when used in conjunction with data derived from chromatographic methods. Table 2 (p. 85) gives data for those pesticides which show significant UV absorption.

MASS SPECTROMETRY

This technique, when combined with gas chromatography, provides the most comprehensive screening method available, with high specificity and sensitivity, and wide applicability. It can be used for identification and quantification down to very low concentrations, using the technique of selected ion monitoring whereby the mass spectrometer acts as a sensitive and specific detector for the gas chromatograph. Further information on this technique may be found under Mass Spectrometry (p. 259).

Chromatographic Methods

THIN-LAYER CHROMATOGRAPHY

This technique represents a cheap, simple, and quick method for screening pesticides, but it suffers from the disadvantage that there is no single system and location method to cover all the compounds of

interest. Nevertheless, when combined with ultraviolet spectrophotometry, it can provide a useful first approach to screening for pesticides. Alternative methods can then be used for confirmation. Further information on the technique can be found under Thin-layer Chromatography (p. 160). A thin-layer system for the separation of organophosphorus pesticides (System TW) is described on p. 177.

HIGH PRESSURE LIQUID CHROMATOGRAPHY

This method is of value for dealing with compounds which are thermally labile and therefore are not suitable for gas Chromatography. However, reported methods have usually described the analysis of specific pesticides, or groups of pesticides, and screening methods are not yet available, partly because pesticides which do not absorb in the ultraviolet cannot be detected with the commonly-used UV detector.

GAS CHROMATOGRAPHY

This is the most useful technique for screening pesticides since it has wide applicability and sensitivity, and utilises equipment which is readily available in most laboratories. Over 95% of all pesticides may be chromatographed intact or as a simple derivative; in some cases there is a clearly defined decomposition product although quantification may be difficult if the extent of decomposition is not reproducible. The sensitivity of the method is high using a flame ionisation detector; when specific detectors are used, e.g. electron capture, alkali flame ionisation, or flame photometric detectors, even lower concentrations in body fluids may be detected.

COMPREHENSIVE SCREENING PROCEDURE

This procedure employs an initial gas chromatographic screen followed by gas chromatography-mass spectrometry to provide the final confirmation. The details suggested here will cover most compounds and situations which are likely to be encountered by the toxicologist, but they may be varied to suit a particular analysis.

Extraction

Samples which are encountered may be proprietary formulations (solid or liquid), beverages or foodstuff's, and body fluids or tissues (stomach contents, blood, urine, or viscera). As a consequence, it is difficult to describe a single extraction procedure which will encompass all these possibilities.

Furthermore, the extraction of body fluids is complicated by the fact that certain pesticides may be decomposed by acids or alkalis. For example, the substituted ureas are hydrolysed by dilute acid or alkali, and substituted *N*-methylcarbamates decompose in alkaline media. The organophosphorus insecticides are also hydrolysed in alkali and certain members of the class, e.g. azinphos-methyl, diazinon, and malathion, are also unstable in acid.

EXTRACTION SCHEME

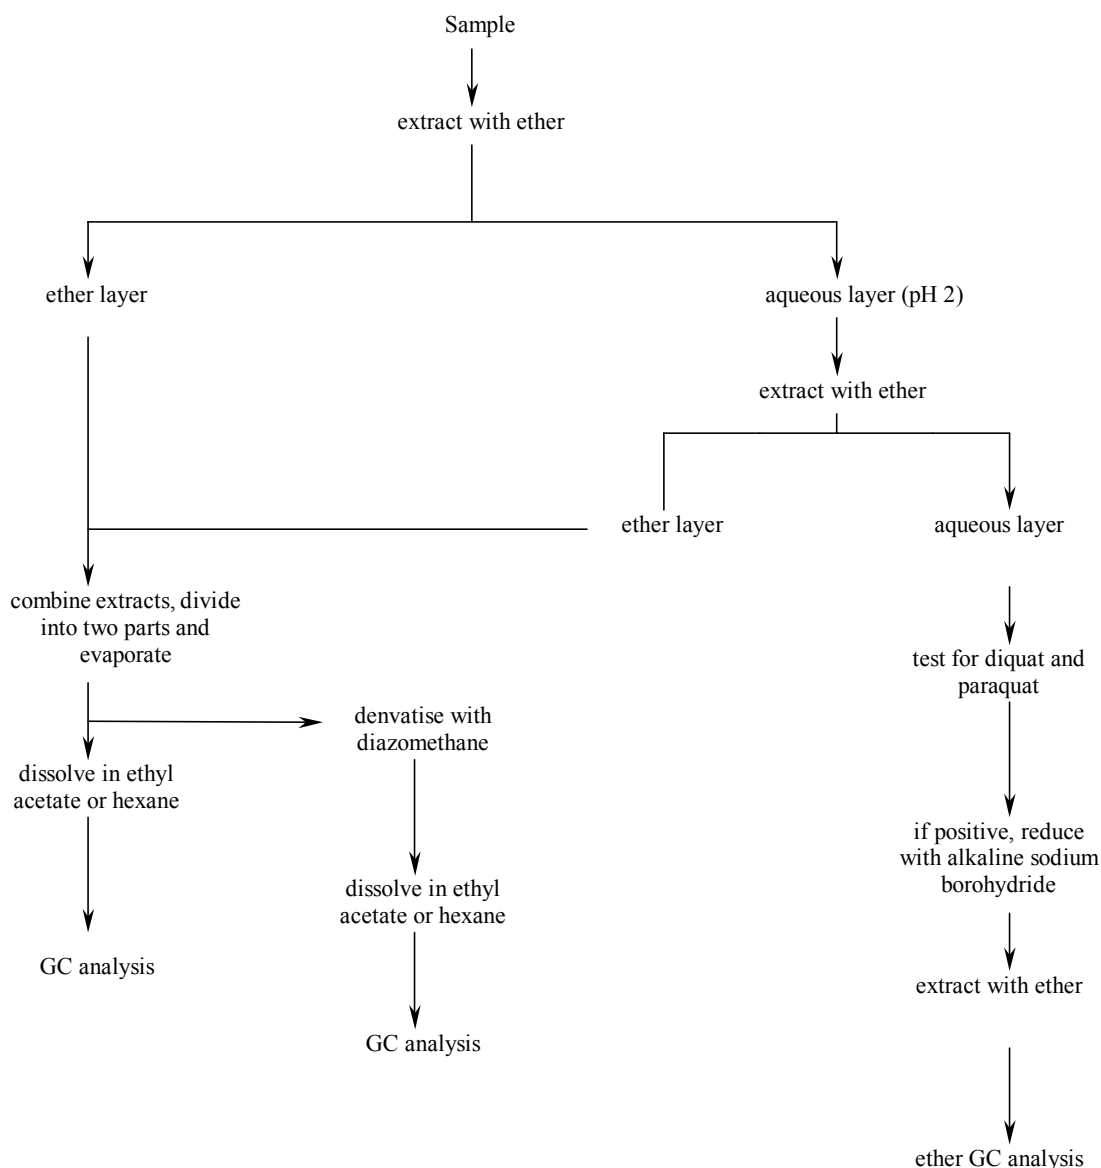

The extraction scheme illustrated below is suitable for dealing with formulated products, beverages, foodstuff's, and stomach contents, but would require modification for use with blood, urine, or tissues. These modifications would reflect the quantity of the specimen available, the suspected concentration, and whether the nature of the pesticide is known. The acid or base stability and the likely extent of metabolism must also be considered.

Method. If the sample is a solid or a semi-solid, homogenise it with an equal quantity of water. In the case of foodstuff's or stomach contents, treat the homogenate with saturated calcium chloride solution, allow to stand overnight, and filter. Extract an aliquot of the sample or of the filtered homogenate with an equal volume of redistilled ether, separate, and retain the ether fraction. Adjust the aqueous fraction to pH 2 by the addition of 2M hydrochloric acid, extract with an equal volume of ether, and combine the two ether fractions. Retain the aqueous fraction for later examination.

Divide the combined ether fractions into two equal portions, evaporate each portion to dryness and retain one of the residues. Treat the other ether residue with about 200 μ l of an ethereal solution of diazomethane, allow to stand at room temperature for 30 minutes, and then evaporate to dryness.

Dissolve this residue and the previously retained residue, separately, in 25 μ l of ethyl acetate or hexane (do not use ethanol or acetone which can react with the decomposition products of substituted ureas). Examine the underivatized and methylated extracts by gas chromatography using the procedure described below.

Both underivatized and methylated samples are examined because uracil herbicides give a mixture of products on methylation and should be chromatographed in their underivatized forms, whereas carboxylic acid pesticides, e.g. chlorinated phenoxy acid herbicides, are best examined as methyl derivatives.

Test a portion of the previously retained aqueous extract for the presence of paraquat and/or diquat, using the Sodium Dithionite test (see p. 144). If this test gives a positive result, adjust the remaining aqueous extract to pH 10 by the addition of *dilute ammonia solution*, add 50 mg of sodium borohydride, allow to stand at room temperature for 30 minutes, and extract with an equal volume of redistilled ether. The ether extract contains the monoene and diene reduction products which can then be confirmed by GC and/or GC-MS.

Gas Chromatography Procedure

Gas chromatography should be carried out with a packed column, using temperature programming, and with an effluent splitter fitted to a dual FID/AFID

detection system. System GA (see p. 192) may be used or, preferably, the following system.

System GK

COLUMN. 3% OV-17 on 80-100 mesh Gas Chrom Q, 3 ft x 1/4 in internal diameter (1 m x 6 mm).

COLUMN TEMPERATURE. Programmed at 10° per minute from 100° to 260°.

CARRIER GAS. Nitrogen at 50 ml/min. Inject 1 to 5 µl of the sample extract, together with 1 µl of a solution of caffeine in ethyl acetate containing 1 mg/ml, and determine the relative retention time with respect to this internal standard.

RETENTION DATA. Retention indices for pesticides in System GA, and relative retention times for pesticides in System GK, are given in Table 1

(p. 81) and in the index to Gas Chromatographic Data in Part 3.

Mass Spectrometry Requirements

The requirements for the GC-MS procedure are a gas chromatograph, preferably fitted with the same type of column as that described above, linked via a jet separator to a low resolution mass spectrometer. The latter can be either a magnetic sector instrument or a quadrupole filter, but there is no need for fast scanning facilities if a packed column is used. However, it is of considerable advantage if selected ion monitoring facilities are available for dealing with concentrations too low to permit normal scanning procedures, and this is more conveniently implemented on a quadrupole instrument. As the majority of pesticides produce characteristic electron impact (EI) spectra, with little ambiguity so far as interpretation is concerned, there is little need for an instrument capable of chemical ionisation as well. A data system for automatically acquiring and storing spectra, and capable of library searching, is desirable though not absolutely necessary if GC-MS is only used for confirmation of the identity of one or two components. Mass spectral peaks for over 200 pesticides are listed in numerical order of base peak in the index to Mass Spectral Peaks of Pesticides in Part 3.

ANALYSIS OF INSECTICIDES AND HERBICIDES BY GC-MS

GC and GC-MS have been widely applied in the analysis of pesticides, but most of the reported methods have been concerned with detection of residue amounts. Such methods are not directly relevant to clinical and forensic toxicology where the concentrations encountered are usually several orders of magnitude higher. The mass spectra of a wide range of pesticides have been described comprehensively by Safe and Hutzinger (1973), and further details of fragmentation mechanisms may be found there.

Insecticides

CHLORINATED HYDROCARBONS

These insecticides, e.g. dicophane and its analogues, isomers of hexachlorocyclohexane, and bridged polycyclic chlorinated compounds, may be chromatographed satisfactorily without prior derivatisation. A typical separation is shown in Fig. 1, using the dual detection system. Although greater

Fig. 1. Gas chromatograms of some chlorinated hydrocarbon insecticides using dual detection (FID/AFID). A, lindane; B, caffeine (internal standard); C, dieldrin; D, dicophane.

sensitivity could be obtained using electron capture detection, this would not normally be required in cases of homicidal or suicidal poisoning because of the large quantities (several grams) usually ingested. In fact, most of the deaths attributed to chlorinated insecticides are due to the solvents, such as kerosene and toluene, in which they are formulated. Dicophane and its analogues (methoxychlor and dicofol) show interesting mass spectral behaviour. Dicophane and methoxychlor occur in commercial products as a mixture of the *op'* and *pp'* isomers, the latter being the major component. The isomers of dicophane are readily separated by the GC system

but their mass spectra are virtually identical. However, the spectra of the analogous isomers of methoxychlor are quite different in respect of the intensity of the ion at m/z 121 which could be due to a methoxy-substituted tropylium ion (Fig. 2). In general, the fragmentation patterns for 1,1,1-trichlorodiphenylmethane derivatives are dominated by the initial loss of CCl_3 , leading to a base peak at m/z 235 for dicophane and at m/z 227 for methoxychlor.

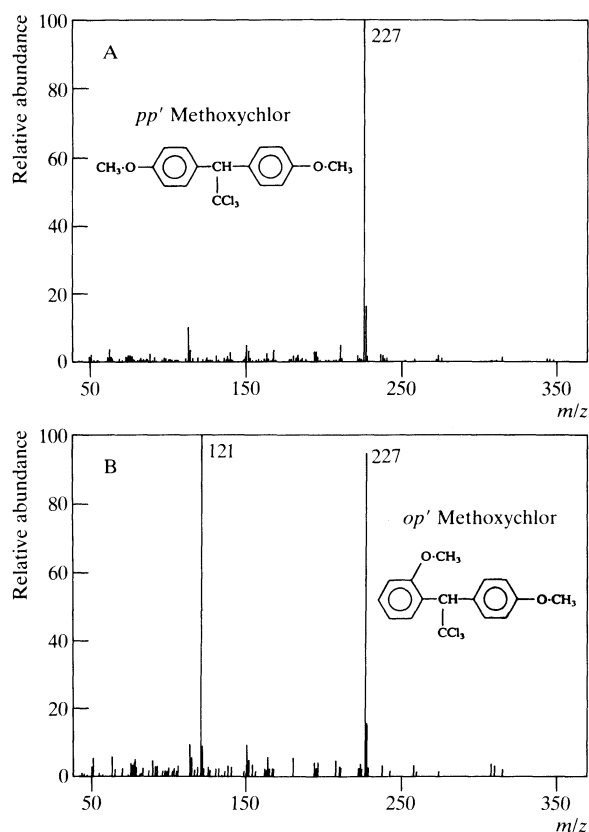

Fig. 2. Electron impact mass spectra of methoxychlor isomers.

The mass spectrum of dicofol (a diphenylmethanol derivative) depends on the type of inlet system used on the mass spectrometer. The spectrum obtained by GC-MS (Fig. 3A) is identical with that of *pp'*-dichlorobenzophenone, presumably formed by elimination of chloroform from the parent compound in the heated injection port. On the other hand, the direct insertion probe spectrum (Fig. 3B)

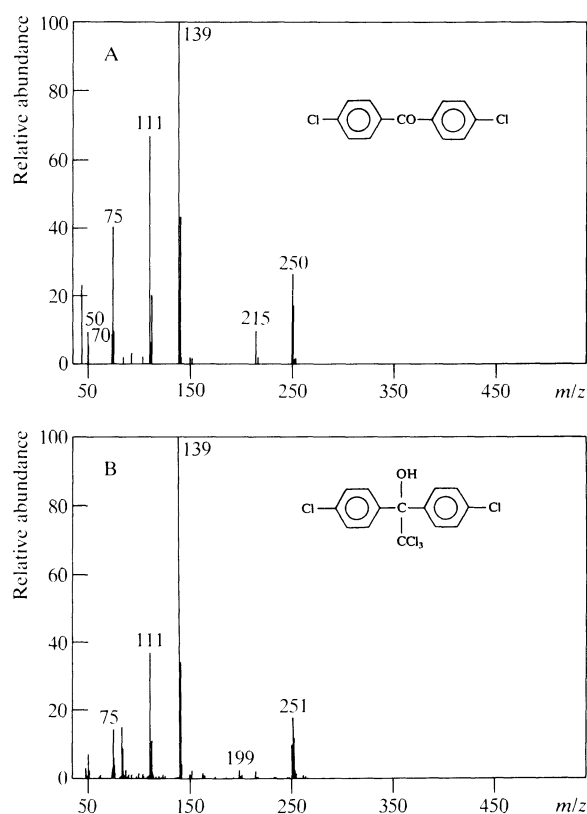

Fig. 3. Electron impact mass spectra of dicofol. A, by GC-MS; B, by direct insertion probe.

can be rationalised in terms of the spectrum of dicofol itself (yielding the ion at m/z 251) superimposed on that of *pp'*-dichlorobenzophenone and chloroform (the ions at m/z 83 and 85 being due to CHCl_2^+). The isomeric hexachlorocyclohexanes are the main components of technical benzene hexachloride, the γ -isomer lindane being an important insecticide in its own right. The mass spectrum of lindane features the expulsion of Cl and HCl from both the molecular ion and subsequent fragment ions.

Bridged polycyclic chlorinated hydrocarbon insecticides include the dimethanonaphthalenes and methanoindenes. Their spectra are dominated by retro Diels-Alder fragmentation reactions which are accompanied, or preceded, by expulsion of Cl and/or HCl . A typical dimethanonaphthalene is aldrin, the mass spectrum of which is shown in Fig. 4. The corresponding epoxide of this compound, dieldrin, shows similar features.

Fig. 4. Electron impact mass spectrum of aldrin.

Technical chlordane is a mixture of chlorinated methanoindenes and consists of over 45 components, the identity of some of these being shown in Fig. 5. The multiplicity of components arises as a by-product of its synthesis by the Diels-Alder addition of hexachlorocyclopentadiene with cyclopentadiene to yield chlordene which is then chlorinated.

Fig. 5. ORGANOPHOSPHORUS COMPOUNDS

The organophosphorus insecticides are tending to replace the organochlorine compounds. They may be conveniently divided into four main structural groups:

Phosphorodithioates

Phosphorothionates

Phosphorothiolates

Phosphates

(R = alkyl; Z includes a wide variety of chemical structures)

This class of insecticides and the *N*-methylcarbamates are inhibitors of cholinesterase enzymes. Hence, poisoning involving these substances is usually diagnosed by measuring the cholinesterase activity of blood, serum, or plasma (see p. 23). However, other poisons such as fluoride and also various diseases have a similar effect. The screening of these compounds by GC is greatly assisted because detection by AFID has a ten-fold higher sensitivity to phosphorus-containing compounds compared with those containing nitrogen.

A feature of the fragmentation pathways of these compounds is that common ions can be used to determine the class or sub-class. For example, ions at m/z 158, 125, and 93 are characteristic of *OO*-dimethyl phosphorodithioates, while analogous ions shifted 28 mass units at m/z 186, 153, and 121 are characteristic of the *OO*-diethyl phosphorodithioates. The final identification is given by either the molecular ion (which may vary widely in abundance) or the diagnostic ions reflecting the nature of the Z moiety. However, the picture is complicated by an overlap of the fragmentation pathways and also by thermal isomerisation in the mass spectrometer source, the result of which is that the spectra of the phosphorothiolates and phosphorothionates show

common features. This can also occur during the gas chromatography of these compounds.

CARBAMATES

The carbamate esters fall into two general classes according to their chemical structure and biological activity. The *N*-methylcarbamates are insecticides while the *N*-arylcarbamates are mainly herbicides. Since this classification is not entirely rigorous and they are structurally related, both classes are here considered together.

The differences in chemical structure lead to differences in their thermal stabilities, the *N*-methylcarbamates undergoing thermal decomposition to produce a substituted phenol by the elimination of methyl isocyanate

The *N*-arylcarbamates are much more thermally stable and are amenable to GC analysis. A wide range of carbamates can be successfully chromatographed intact on a low-loaded Carbowax 20M column, using a modified support and moderate (185°) column and injection port temperatures. However, under the conditions described for System GK, all the *N*-methylcarbamates show extensive decomposition and the mass spectra are dominated by molecular ions arising from their phenolic decomposition products. By contrast, the *N*-arylcarbamates, e.g. propham and chlorpro-pham, can be analysed on this system without any noticeable decomposition. The *NN*-dimethylcarbamate pirimicarb is also stable under these conditions. The mass spectra of these compounds exhibit molecular ions which are of low intensity but which, together with significant diagnostic ions, permit conclusive identification.

PYRETHRINS

The 'natural' pyrethrin insecticides are esters derived from the alcohols cinerolone, jasmololone, and pyrethrolone (Fig. 6). Extracts of pyrethrum, the dried flowerheads of *Chrysanthemum cinerariae-folium*, contain a mixture of six of these ester (Fig. 6) and are commonly available with the addition of the pyrethrum synergist piperonyl butoxide. Variations on these basic structures have

Fig. 6. Structure of natural pyrethrin insecticides.

Fig. 7. Structure of synthetic pyrethrin insecticides.

led to the introduction of the closely related synthetic pyrethrin insecticides, the structures of the important ones being shown in Fig. 7. All these compounds can be chromatographed readily, but since they contain only C, H, and O, they do not show selective response to AFID. The mass spectra of these compounds show only very weak molecular ions, the major ions being those which result from fission at the ester linkage followed by subsequent fragmentation of these ions. All of the pyrethrin insecticides can be identified using the two characteristic ester fission ions, together with other diagnostic ions in their mass spectra.

Herbicides

CHLORINATED PHENOXY ACIDS

Substituted phenoxy acids used as herbicides have the general formula

where $n = 1, 2$, or 3 and R_1 and R_2 are CH_3 , Cl , or H . They are available in commercial products as salts (sodium, potassium, or alkylamine) or as long-chain esters, particularly iso-octyl esters. The esters may be chromatographed directly, but the salts must be converted to their corresponding methyl esters after extraction of the free acids. A GC trace typical of this group of compounds is shown in Fig. 8. As expected, no response is obtained with AFID.

The fragmentation pathways for the methyl esters are strongly dependent on the type of acid, i.e. whether a derivative of phenoxyacetic acid, phenoxypropionic acid, or phenoxybutyric acid, and on the nature of the substitution of the aromatic ring. The methyl esters of chlorinated phenoxyacetic and phenoxypropionic acids show reasonably abundant molecular ions (about 20% relative to the base peak) which, together with the chlorine isotope patterns, permit easy identification of these compounds. In contrast, the spectra of the methyl esters of chlorinated phenoxybutyric acids are dominated by the fragment ion at m/z 101, with only low abundance of molecular ions. However, the spectra also show

Fig. 8. Gas chromatograms of the methyl esters of some chlorinated phenoxy acids. A, methylchlorophenoxyacetic acid; B, dichlorophenoxyacetic acid; C, trichlorophenoxyacetic acid; D, caffeine (internal standard).

characteristic fragment ions which are sufficient for full identification of these compounds. The derivatives of phenoxyacetic acid containing a chlorine atom in the *ortho* position (i.e. 2,4-D and 2,4,5-T) exhibit a base peak corresponding to the loss of this chlorine atom, whereas the analogous derivatives of phenoxypropionic and phenoxybutyric acids do not. Those compounds with a methyl substituent on the benzene ring, i.e. methylchlorophenoxyacetic acid (MCPA) and its propionic and butyric acid analogues, show abundant ions at m/z 125 and 107; these have been assigned to the chlorotropylium and hydroxytropylium ions, respectively. The iso-octyl esters of the chlorinated phenoxy acid herbicides all show intense ions at m/z 41, 55, 57, 69, 71, and 85, which are typical only of long-chain aliphatic hydrocarbon derivatives, but high-mass ions of significant intensity are also available for their full identification.

SUBSTITUTED UREAS

These herbicides contain nitrogen and respond to both FID and AFID. However, the analysis of these compounds is complicated by their thermal instability. For example, the total ion current trace obtained from the GC-MS of a methanolic solution of monolinuron shows four peaks (Fig. 9). The formation of these peaks is illustrated in Fig. 10. This thermal decomposition appears to be general for the substituted ureas and reaction of substituted phenyl isocyanates with higher alcohols also occurs. As certain substituted alkyl phenylcarbamates are used as pesticides in their own right, inert solvents such as ethyl acetate or hexane should always be used for injection. The mass spectra of the thermal

Fig. 9. Total ion current (TIC) trace obtained from a methanolic solution of monolinuron. A, 4-chlorophenyl isocyanate; B, 4-chloroaniline; C, methyl *N*-(4-chlorophenyl)carbamate; D, monolinuron.

Fig. 10. Decomposition mechanisms of monolinuron in methanol.

decomposition products show abundant molecular ions with appropriate characteristic isotope patterns which permit conclusive identification of the original substituted urea.

TRIAZINES

Most of the commercial triazine pesticides are trisubstituted 1,3,5-triazines of the general structure

where X=C1 or SCH₃, and Y and Z are usually alkylamino groups.

Since these herbicides contain at least five nitrogen atoms, they show enhanced AFID/FID ratios. With the exception of cyanazine, the spectra of these compounds are characterised by abundant molecular ions and identification is straightforward. Trietazine and aziprotryne are two members of this class of herbicide whose mass spectra differ from those of the main group but they exhibit highly characteristic features.

URACILS

The most commonly used pyrimidine herbicides are the uracils, e.g. bromacil and terbacil, which have the following structures

	R ₁	R ₂	X
Bromacil	H	CH ₃ ·CH ₂ ·CH(CH ₃)—	Br
N-Methylbromacil	CH ₃	CH ₃ ·CH ₂ ·CH(CH ₃)—	Br
Terbacil	H	(CH ₃) ₃ C—	Cl
N-Methylterbacil	CH ₃	(CH ₃) ₃ C—	Cl

	R ₁	R ₂	X
Bromacil	H	CH ₃ ·CH ₂ ·CH(CH ₃)—	Br
<i>N</i> -Methylbromacil	CH ₃	CH ₃ ·CH ₂ ·CH(CH ₃)—	Br
Terbacil	H	(CH ₃) ₃ C—	Cl
<i>N</i> -Methylterbacil	CH ₃	(CH ₃) ₃ C—	Cl

Fig. 11. Total ion current (TIC) trace of methylated terbacil. A, *O*-methylterbacil; B, *N*-methylterbacil; C, terbacil.

A total ion current trace obtained from the GC-MS of terbacil methylated with diazomethane is shown in Fig. 11. From this it can be seen that derivatisation by this method leads to a mixture of products. It is for this reason that the analytical scheme incorporates an initial gas chromatographic step prior to methylation.

The mass spectra of bromacil and terbacil and their *N*-methyl derivatives show only weak molecular ions, but they have the isotope patterns expected from bromine and chlorine compounds, respectively. The major ions arise from $[M-55]^+$ and $[M-56]^+$ and also reflect the halogen substituent. Less abundant, but highly characteristic ions, corresponding to $[M-99]^+$ and $[M-98]^+$, are formed by retro Diels-Alder fragmentations.

QUATERNARY AMMONIUM HERBICIDES

Paraquat and diquat are the most important members of this class and are readily available in various proprietary formulations. Their analysis is complicated by the fact that they are not extractable by conventional liquid/liquid extraction procedures, nor can they be gas chromatographed in their original form. Ingestion of large amounts (several grams) of paraquat leads rapidly to death, and in these cases ultraviolet spectrophotometry may be used. However, death can occur even with smaller doses (300 mg), and the concentrations in body fluids are consequently much lower. Specific radioimmunoassay methods have been developed (T. Levitt, *Proc. Analyt. Div. Chem. Soc.*, 1979, 16, 72-76, and D. Fatori and W. M. Hunter, *Clinica chim. Acta*, 1980, 100, 81-90).

Fig. 12. Reduction of paraquat and diquat with sodium borohydride.

Fig. 13. Electron impact mass spectra of A, paraquat diene and B, paraquat monoene.

An alternative method, based on gas chromatography, involves the initial reduction of paraquat or diquat by sodium borohydride to produce the diene or monoene, as shown in Fig. 12. These products,

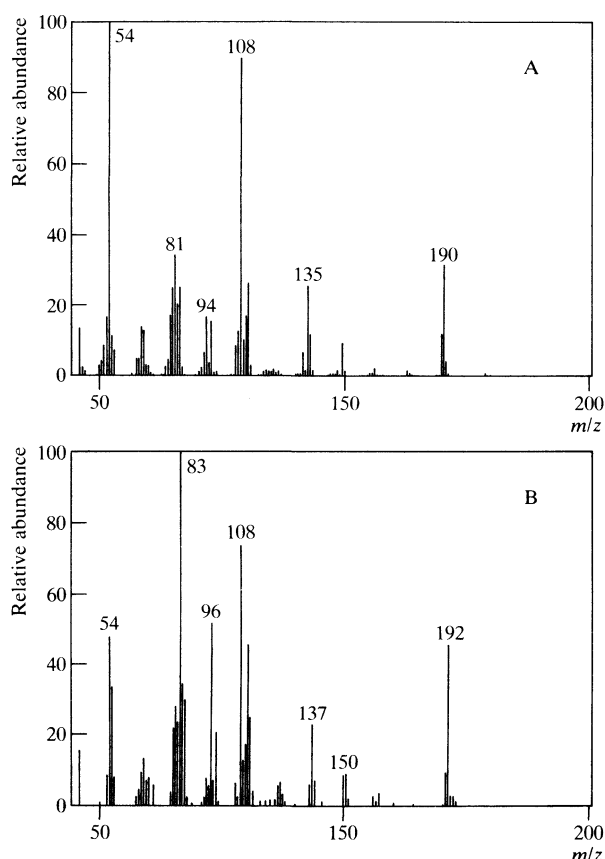

Fig. 14. Electron impact mass spectra of A, diquat diene and B, diquat monoene.

which are extractable by ether from alkaline solution, may be gas chromatographed; the limit of detection of the method is 25 ng/ml using AFID. The mass spectra of the monoene and diene formed from paraquat and diquat are shown in Figs 13 and 14, respectively. The spectra of all these products exhibit abundant molecular ions which, together with characteristic fragment ions, readily permit the identification of the original herbicide.

Table 1. Classification of pesticides

Abbreviations used in the table

A	Acaricide
CB	Carbamate insecticide or herbicide
CH	Chlorinated hydrocarbon insecticide
CP	Chlorinated phenoxy acid herbicide
F	Fungicide
GCDP	Gas chromatography decomposition product
H	Herbicide
I	Insecticide
Misc.	Miscellaneous
OP	Organophosphorus insecticide
PY	Pyrethrin insecticide
QA	Quaternary ammonium herbicide
RRT	Retention time relative to caffeine
SU	Substituted urea herbicide
TR	Triazine herbicide
UR	Uracil herbicide
*	Monograph for this pesticide in Part 2

Toxicity rating

Toxicity rating	(for a 70 kg person)
1. Non-toxic	> 1000 g
2. Slightly toxic	500 to 1000 g
3. Moderately toxic	28 to 500 g
4. Very toxic	4 to 28 g
5. Extremely toxic	500 mg to 4 g
6. Super toxic	< 500 mg (< 10 drops, a taste)

Drug Abuse in Sport

M. S. Moss and D. A. Cowan

Drug abuse in sport is often called doping, the international word 'dope' being used both as a noun and as a verb. The Oxford English Dictionary gives its origin as the Dutch word 'doop' which means 'Christian baptism'. It seems likely that the religious fervour associated with this ceremony resulted in the use of the same word, in a somewhat cynical and contemptuous way, to describe the state of intoxication and euphoria induced by certain drugs. The word does not appear in this context before the 20th Century despite the practice of horse 'nobbling', which was known well before this time. For example, the account of the famous trial of Daniel Dawson, publicly hanged at Cambridge in 1812 for poisoning racehorses with arsenic, reveals that drinking troughs in some stables were padlocked. Dope (described as 'exciting substances') was also banned in races in Worksop in 1666. The word appears to have come into use at the turn of the century, and it is probably associated with the rise of the pharmaceutical industry.

The abuse of drugs in an attempt to enhance performance in human sporting competitions is not new. For example, the Greek authors Phylostratos and Galen commented on the ethics of competitors in the Olympics who would take any preparation to improve their performance. Roman gladiators were often drugged to make their fights more lusty and bloody as demanded by the spectators.

The effect of drugs on performance is often extremely difficult to determine, and there is little published work for any species. The results which have been published are often conflicting, some workers suggesting an increase in the competitor's performance and others suggesting no improvement. Changes in speed of less than 1% cannot be demonstrated with statistical significance because of the many variable and uncontrollable factors, yet an improvement of only 1% represents a lead of about 6 lengths in a horse race over one mile.

Although the toxic side-effects of drugs are less difficult to ascertain, the conclusions drawn from the available data are often circumstantial, e.g. the possible links between taking anabolic steroids and liver cancer. Nevertheless, there is sufficient evi-

dence of the harmful effects when certain drugs are misused to justify their prohibition from sports competitions.

No controlling body in any field of sport has explicitly defined doping, despite banning the practice. Many horse-racing authorities now define a dope by its pharmacological action (Table 1). If any drug (or metabolite) in any of the listed categories is found in a sample of body fluid from a racehorse, this constitutes an offence. The list of prohibited substances used internationally by many racing authorities, including the British Jockey Club, is comprehensive, and the intention is to ban the use of any drug in racehorses at the time of competition.

Table 1. Prohibited substances under the rules of horse racing

Drugs which act on the autonomic system
the cardiovascular system
the central nervous system
Drugs which affect the coagulation of blood
the gastro-intestinal function
the immune system and its responses
Analgesics, antipyretic and anti-inflammatory drugs
Antibiotics, synthetic antibacterial and antiviral drugs
Antihistamines
Antimalarial and other antiparasitic agents
Cytotoxic substances
Diuretics
Endocrine secretions and their synthetic counterparts
Local anaesthetics
Muscle relaxants
Respiratory stimulants
Sex hormones, anabolic steroids and corticosteroids

By contrast, the stated intention of the Medical Commission of the International Olympic Committee is to ban those drugs which are likely to be harmful when misused (Table 2), but with the minimum of interference with the normal therapeutic use of drugs. Thus, a competitor who is undergoing a legitimate course of treatment is not disqualified. However, this creates many problems in deciding which drugs should or should not be prohibited, and whether or not a competitor requiring a particular drug treatment should be allowed to compete. The International Olympic Committee and the International Amateur

Athletic Federation list examples of prohibited drugs according to their pharmacological classification. However, they are often far from explicit, using the phrases 'related compounds' and 'chemically or pharmacologically related compounds'. Some horse-racing authorities take action on a report of the presence of any foreign compound, even if not positively identified.

Table 2. Drugs disallowed by various human sports bodies

Psychomotor Stimulants Amphetamine, benzphetamine, cathine, chlorphentermine, cocaine, diethylpropion, dimethylamphetamine, ethylamphetamine, fencamfamine, fenproporex, meclofenoxate, methylamphetamine, methylphenidate, pemoline, phendimetrazine, phenmetrazine, phentermine, pipradrol, prolintane, and related compounds

Sympathomimetic Amines Clorprenaline, ephedrine, etafedrine, isoetharine, isoprenaline, methoxyphenamine, methylephedrine, and related compounds

Miscellaneous Central Nervous System Stimulants

Amphetamine, bemegride, doxapram, ethamivan, mephentermine, pentetazocine, picrotoxin, strychnine, and related compounds

Narcotic Analgesics Anilidine, codeine, dextromoramide, diamorphine, dihydrocodeine, dipipanone, ethylmorphine, hydrocodone, hydromorphone, levorphanol, methadone, morphine, oxycodone, oxymorphone, pentazocine, pethidine, phenazocine, piritramide, thebacon, tramperidine, and related compounds

Anabolic Steroids Clostebol, ethylestrenol, fluoxymesterone, methandienone, methandrol, methenolone, methyltestosterone, nandrolone, oxandrolone, oxymetholone, stanolone, stanozolol, testosterone, and related compounds

The position regarding excessive quantities of normal nutrients is even more confused. Clearly they cannot be included in a prohibited list, yet there is no doubt that certain vitamins (notably B₁, C, and E) have been used in large doses with the intention of affecting performance. In addition, substances such as caffeine are allowable in human sport since they are ingested in normal beverages. However, because of the possibility of taking massive doses to enhance performance, their prohibition has been considered. In such cases, measurement of the concentration in a body fluid is essential in establishing a malpractice. The situation with these normal nutrients is not unlike that for certain endogenous compounds such as hydrocortisone and testosterone and their respective trophic hormones (see below).

The drugs most often reported in horses by the Association of Official Racing Chemists for the years 1959, 1969, and 1979 are presented in Table 3. The most striking trend is the increasing use of anti-inflammatory drugs throughout this period,

representing for the respective years 14%, 21%, and 28% of all drugs reported. The apparently sudden appearance of fentanyl and butorphanol is the result of the recent introduction of tests for these compounds. There has been no comparable recording of drugs encountered in human sport.

Table 3. Drugs most commonly reported by the Association of Official Racing Chemists as occurring in horses, in order of frequency

1959	1969	1979
Caffeine	Procaine	Phenylbutazone
Procaine	Pentazocine	Flunixin
Amphetamine	Phenylbutazone	Methocarbamol
Dipyron	Caffeine	Caffeine
Theobromine	Amphetamine	Procaine
Phenylbutazone	Theobromine	Fentanyl
Morphine	Methylphenidate	Butorphanol
Phenobarbitone	Oxyphenbutazone	Theobromine
Theophylline	Methylamphetamine	Oxyphenbutazone
Nikethamide	Dipyron	Guaiphenesin
Thiamine	Prednisolone	
Lignocaine		
Mephentermine		
Atropine		

Sampling

Sample collecting procedures must take into consideration both scientific and legal aspects. The health of the individual being sampled must be safeguarded; incorrect labelling, contamination, or sample-switching must be avoided; the rights of interested parties, generally the owner and trainer of an animal or the individual or team in human sport, must be safeguarded against error by the analyst.

Most horse-racing authorities in Europe divide samples into two portions at the time of sampling, so that the trainer of the horse can arrange a separate analysis on his own behalf. This is not a general practice and is not used in North America. The International Olympic Committee and the International Amateur Athletic Federation always provide a second portion for defence use. This is to be opened only after the first sample has been found to contain a banned drug, and after the competitor has been notified and invited to attend the second analysis, with his own expert if he so wishes. The practice of sample division has been reviewed (M. S. Moss, 1979).

URINE

This is the preferred body fluid in all species. Its collection is non-invasive, it is generally available in sufficient quantity, and the drugs or their metabolites tend to be present in relatively high

concentrations. Disadvantages are that a drug may be present as metabolites or in conjugated form, and the parent drug may be present only in a relatively low concentration. Furthermore, the relationship with the concentration in blood is very imprecise.

Urine is collected almost invariably by voiding naturally. Greyhounds urinate very readily after being released from their transporter; 96% of horses in Britain urinate within one hour of racing; humans can generally urinate at will. However, there is the problem of security. Switching of samples is by no means uncommon, because there is usually a period of waiting before obtaining a sample from a dog or a horse, and because of the desire for privacy on the part of man. Racing cyclists have been reported to have carried a rubber bladder of (negative) urine under their arm, connected by a rubber tube to the appropriate discharge point. Horse handlers responsible for collecting a urine sample from their horses sometimes substitute a urine sample of their own. One laboratory has even received a sample of lager purporting to be horse urine. Incidents such as these emphasise the importance of ensuring that a correct collecting procedure is observed. The odour of urines and of the residues produced after solvent extraction generally form a ready distinction between the species. The presence of appreciable quantities of nicotine, cotinine, caffeine, and uric acid in urine provides good evidence of a human source.

Urine samples from greyhounds are caught directly in a bowl held under the animal. For horses, a container held on the end of an extending handle is generally used, e.g. a net held on a metal ring into which is inserted a polythene bag. Metal ladles are unsuitable because the noise produced by the urine falling into them frequently inhibits the horse from urinating further.

BLOOD

The principal advantage of a blood sample is that its integrity is easier to safeguard because it is usually collected by a doctor or veterinary surgeon who is experienced in the procedure. In addition, drug concentrations in blood are more easily interpreted than those in urine, and certain drugs which are not excreted in urine in detectable quantities (e.g. reserpine) can be detected in blood.

Blood is rarely collected from man or the greyhound because of the relative ease of urine sampling. In pistol shooting a small sample (100 μ l) is collected from the competitor in order to confirm the estimated

blood-alcohol concentration following a breathalyser measurement; the present limit is 500 μ g/ml. Blood is being sampled increasingly in horse racing in much of Europe as a second choice when urine is not obtainable, and in New York State for pre-race testing. The Federation Equestre Internationale takes blood from all horses in order to monitor plasma concentrations of phenylbuta-zone when this drug has been detected qualitatively in urine. In some European countries, two 25-ml samples of blood are collected from horses in flat racing and steeplechasing. On the other hand, the Federation Equestre Internationale may order larger volumes than this, up to a total of 150 ml if urine is not available.

SALIVA

The principal disadvantages of saliva are that it is difficult to obtain a useful volume and few drugs are present at a concentration higher than that in plasma. Non-ionised and non-protein-bound drugs in plasma diffuse passively into saliva. Thus, alkaline saliva (as in the horse) tends to concentrate acidic drugs but, because the percentage of unbound acidic drug in plasma is generally very low, concentrations remain lower than the corresponding total plasma concentrations. For drugs of low lipid solubility, and for high salivary flow rates, equilibrium is not established, resulting in concentrations even lower than those predicted on theoretical grounds. The principal value of saliva, therefore, is in the detection of topical contamination resulting from fairly recent oral ingestion.

Saliva is rarely used in any species but the horse. Collection is generally achieved by the use of gauze swabs held in long forceps. Yields rarely exceed 5 g and are often much less. It is essential that only cotton gauze is used for this purpose as certain synthetic fibres contain compounds that may interfere in thin-layer chromatography.

SWEAT

Little information is available on drug secretion into sweat; it is used very little because of the difficulty of excluding topical contamination. It is collected almost exclusively from the horse, the most convenient technique being to use a scraper and absorbent gauze.

VOMIT

This is sometimes used in greyhound racing, and is induced with sodium carbonate.

Analytical Approach

Dope is generally administered at or near the therapeutic dose, and this results in relatively low concentrations in biological fluids. There is usually no evidence as to whether or not a drug has been administered, or what sort of drug it might be. Any drug used in human treatment or in veterinary practice may be found. Furthermore, certain classes of drugs or individual drugs which are not normally associated with acute poisoning in man are often abused in both human and animal sports. Thus, screening procedures must be both sensitive and of wide coverage, and they differ in detail from other analytical schemes. However, the sports chemist enjoys the advantage of examining relatively constant material, usually in fairly fresh condition. He thus has a clearer picture of a normal sample than does the forensic or hospital chemist who may be required to examine a wide variety of materials in various states of decomposition.

METABOLITES

Most screening procedures rely upon the detection of unchanged drug rather than metabolites, despite the fact that many drug concentrations are lower than those of their metabolites. The reason is that drugs are almost always lipophilic and readily extractable from body fluids. Water-solubilisation of drugs is an important process in their detoxification, the most important single reaction being that of metabolic conjugation. In those cases where an unconjugated metabolite is identified, the metabolite itself is often pharmacologically active and also extractable, e.g. theophylline and theobromine from caffeine, and oxyphenbutazone from phenyl-butazone. The identification of the corresponding metabolites is often useful supplementary evidence to support the identification of the parent drug.

In addition, the presence of metabolites in the appropriate concentrations relative to the parent drug helps to support the conclusion that a drug has been administered. Conversely, the absence of expected metabolites might be strong evidence that a sample has been contaminated.

Occasionally, the parent drug is not excreted in urine at a detectable concentration, and a knowledge of the metabolic pathways in the particular species is thus essential. An example of this is the identification of 5α -estrane- 3β , 17α -diol in the urine of horses, or of 19-norandrosterone and 19-nor-etiocholanolone in the urine of humans, to prove administration of the anabolic steroid nandrolone. A few drugs are notable for being excreted in urine almost

entirely in conjugated form as, for instance, apomorphine, fentanyl, nefopam, and pentazocine in the horse. When the presence of these drugs is suspected, hydrolysis before solvent extraction is essential. The metabolism of drugs in the horse has been reviewed (M. S. Moss, 1977).

Drugs can be used either to improve or to impair athletic performance, though in human sport the latter category of drug is unlikely to be used. In sports such as greyhound racing and horse racing, however, decreasing an animal's speed can be a profitable exercise. Hence, sedative drugs are not uncommon in these events and can occur in the acidic, neutral, and basic group extracts. Thus, in horse and dog samples, it is essential that all groups are covered, and these will include steroids, barbiturates, non-steroidal anti-inflammatory drugs, diuretics, and xanthines.

It is apparent that no single analytical scheme will suffice to cover so many different types of compound. For this reason, two types of analysis have come to be recognised; firstly, the general scheme covering the majority of acidic and basic drugs and secondly, target analyses for special drugs or groups. Target analyses are relatively expensive since they cover a smaller number of compounds. Such analyses, therefore, are generally undertaken to meet a special request, or to cover those cases where abuse is believed to exist.

SOLVENTS FOR EXTRACTION

The choice of solvent is limited by the wide range of drugs to be covered, and relatively polar solvents must be used. The choice, therefore, lies between ether and chlorinated hydrocarbons. Because of the importance of the methylxanthines in horse and greyhound doping, one of the extractions should preferably make use of chloroform. If chloroform is used for both the basic and acidic group extracts, the basic group extraction should be performed first in order to avoid the loss of chloroform-soluble salts (e.g. methadone hydrochloride) in the chloroform used to extract the acids. When the sample is urine, the hydroxylated barbiturate metabolites will not be extracted by this process. However, parent barbiturates should be present in sufficient concentration to be detected by gas chromatography. The above considerations are reflected in the design of screening procedures. Techniques of general solvent extraction and drug screening are detailed under Hospital Toxicology and Drug Abuse Screening (p. 3) but full details of suitable procedures are described here in order to take account of certain

special requirements peculiar to screening for doping agents. The method used for gas chromatographic screening for basic drugs is applicable to all species, though different extraction procedures are used for human samples. The additional procedures necessary for non-human samples are described separately.

GAS CHROMATOGRAPHY

The gas chromatographic procedures referred to below will detect a wide range of compounds in urine samples, at concentrations of the order of 1 µg/ml. They depend on the fact that all the compounds of interest contain at least one nitrogen atom and will produce a signal in an alkali flame ionisation detector. The methods of extraction and the selectivity of the detector ensure minimal interference from other compounds which do not contain nitrogen, although certain plasticisers containing phosphorus, such as tributyl phosphate, may produce signals. In addition, other nitrogen-containing compounds which are not prohibited in human sport (e.g. antihistamines) will produce interfering peaks.

Identification is based on retention index; alternatively retention time (relative to a standard) may be used. Details of retention indices or relative retention times of compounds in the systems described below are given in the index to Gas Chromatographic Data in Part 3.

Data obtained using more than one stationary phase will obviously ensure more certain identification; the use of a non-polar, semi-polar, and polar stationary phase is recommended. The identity of a substance may be confirmed using derivative formation and gas chromatography-mass spectrometry, preferably comparing the data obtained with authentic reference material.

SCREENING METHODS FOR STIMULANTS AND NARCOTIC ANALGESICS

Examination of Human Urine

SCREEN A

Method. To 5 ml of the sample in a 10-ml centrifuge tube add 0.5 ml of 5M potassium hydroxide, 3 g of sodium chloride, and 2 ml of freshly-distilled ether containing 10 µg/ml of diphenylamine as a reference standard. Mix thoroughly for 10 minutes on a rotary mixer. Centrifuge, remove about 1 ml of the ethereal layer, and dry with 0.1 g of anhydrous sodium sulphate. Examine 3 µl of this extract by gas

chromatography using 10% Apiezon L and 2% KOH on 80-100 mesh Chromosorb W HP (System GB, p. 193). System GA may also be used.

The use of sodium chloride to increase the ionic strength of the aqueous phase increases the extraction into the ether of many of the compounds, obviating the need for solvent evaporation. Although some polar compounds such as ephedrine are readily extracted in this procedure, it is best suited to less polar compounds.

SCREEN B

This detects the more polar and less volatile drugs and their metabolites, e.g. morphine and codeine glucuronides. Conjugates are cleaved by hydrochloric acid hydrolysis prior to extraction. An antioxidant, such as mercaptoacetic acid or cysteine, should be added to the acid to minimise oxidation of any sensitive compounds during the hydrolysis. The addition of isopropyl alcohol to the extracting solvent, and buffering the urine at pH 9.2, enables most amphoteric compounds to be extracted.

Method. To 5 ml of the sample in a 10-ml centrifuge tube add 0.5 ml of a mixture of *hydrochloric acid* and mercaptoacetic acid (9:1), stopper the tube, heat at 100° for 30 minutes, cool, and add 0.85 ml of 12M sodium hydroxide to neutralise the excess acid; add 2 g of a mixture of sodium bicarbonate and potassium carbonate (3:2) to adjust the pH to 9.2, and extract the hydrolysed mixture with 2 ml of a mixture of ether and isopropyl alcohol (9:1), both freshly distilled and containing 2.5 µg/ml of phenazine as reference standard. Buffer a further 5 ml of the urine to pH 9.2 and extract in the same manner as above but omitting the hydrolysis. Combine the two extracts and evaporate the solvent at 35° under vacuum using a rotary film evaporator. To the drug extract add 50 µl of ethyl acetate and 50 µl of trifluoroacetic anhydride, heat at 65° for 20 minutes, and again evaporate under vacuum as above. To the residue add 0.5 ml of anhydrous ethyl acetate and examine 3 µl by gas chromatography using 3% OV-17 on 80-100 mesh Chromosorb W HP (System GC, p. 193). System GA (p. 192) may also be used.

The formation of the trifluoroacetyl derivatives of phenolic or alcoholic groups increases the volatility of those compounds. The formation of amides from primary or secondary amines will often provide additional information to help identify the compound present.

Examination of Horse Urine

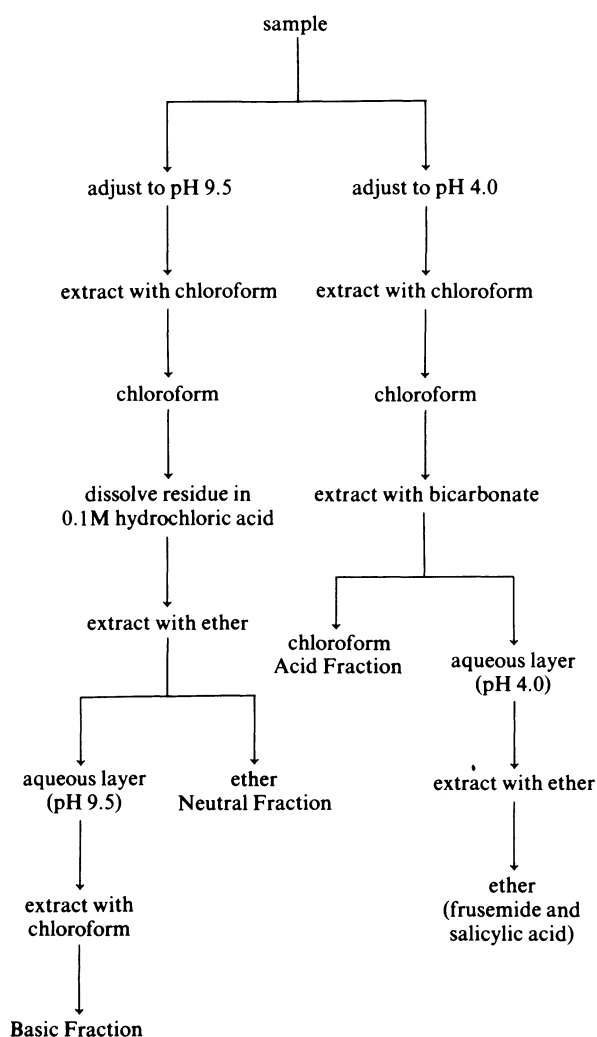

Two methods are described, one using direct solvent extraction, and the other a solid-liquid extraction.

SOLVENT EXTRACTION

The procedure is illustrated below.

Adjust 100 ml of urine to pH 9.5 with 2M sodium hydroxide, and extract with an equal volume of chloroform by rotation in a separating funnel at about 1 revolution per second, in order to avoid the formation of emulsions; separate the solvent layer by filtering through phase-separating paper, add one drop of *hydrochloric acid* and a sintered glass bead, and evaporate to dryness. Redissolve the residue in 10 ml of 0.1M hydrochloric acid by warming on a boiling water-bath for about 2 minutes, and then extract with 25 ml of ether to yield the Neutral Fraction.

Scheme for the solvent extraction of horse urine

Adjust the aqueous phase to pH 9.5 by adding 2 g of a mixture of borax and sodium carbonate (20:1), extract with 20 ml of chloroform, filter the chloroform layer through a cotton wool plug, add 1 drop of *hydrochloric acid* and a sintered glass bead to the filtrate, and evaporate to dryness to yield the Basic Fraction.

Adjust 100 ml of urine to pH 4.0 with *dilute sulphuric acid*, extract with 100 ml of chloroform, wash the solvent layer with a 5% solution of sodium bicarbonate, filter the solvent through a phase-separating paper, and evaporate to yield the Acid Fraction. If either frusemide or salicylic acid is suspected, adjust the pH of the sodium bicarbonate layer to 4.0 with *dilute sulphuric acid*, extract with 25 ml of ether, and retain the ether extract for analysis.

SOLID-LIQUID EXTRACTION

An alternative procedure uses the non-ionic resin Amberlite XAD-2 (see Reagent Appendix). Adjust the urine sample to pH 9.5 with 2M sodium hydroxide, add 6 g of XAD-2 for each 100 ml of urine, agitate the mixture for 10 to 15 minutes, and remove the urine. Resuspend the resin in 20 ml of *ammonia buffer* (pH 9.5), transfer to a column, and pump the resin under vacuum to remove the buffer and to draw air through the resin; partial drying of the resin at this stage reduces the subsequent elution of material which may mask the presence of drugs. Wash the resin with five 5-ml portions of a mixture of ethyl acetate and methylene chloride (1:1), filter the solvent through phase-separating paper, add a drop of *hydrochloric acid*, and evaporate to dryness to yield the Basic Fraction.

Add to the column about 15 ml of a 10% solution of *acetic acid*, allow to stand for about 5 minutes, pump dry under vacuum, and elute with solvent as described above. Evaporate the solvent on a boiling water-bath to yield the Acid Fraction.

TREATMENT OF EXTRACTS OF HORSE URINE

Neutral Fraction

Few doping agents occur in this group, apart from the neutral steroids which are covered by a separate procedure. Benzocaine has occurred occasionally in this group. The neutral sedatives such as carbamates and methypylone would also be extracted, but these have not been reported as doping agents. Ureides such as carbromal do not present a problem as they are metabolised extremely rapidly

in horses, very large doses being tolerated with no apparent effect. This group can be screened by gas chromatography using 2.5 % SE-30 on 80-100 mesh Chromosorb G (System GA, p. 192).

Basic Fraction

The extract is dissolved in methanol and a portion equivalent to about 1 ml of the original urine should be screened by gas chromatography using 10% Apiezon L and 2% KOH on 80-100 mesh Chromosorb W HP (System GB, p. 193), and 3% OV-17 on 80-100 mesh Chromosorb W HP (System GC, p. 193). System GA (p. 192) may also be used. Examine the methanol extract by thin-layer chromatography using a silica gel G plate and developing with a 100:1.5 mixture of methanol: *strong ammonia solution* (System TA, p. 167). Spray the plate with *acidified iodoplatinate solution* followed 15 minutes later by *Ludy Tenger reagent*, the latter spray is useful for confirming the presence of methylxanthines which may frequently be found in both the acidic and basic fractions. Rf values for compounds in System TA are given in the index to Thin-layer Chromatographic Data in Part 3.

Acid Fraction

This extract contains the very important non-steroidal anti-inflammatory drugs as well as the weak acids theophylline and theobromine. It should be noted that many of the non-steroidal anti-inflammatory drugs are carboxylic acids, which are divided between the bicarbonate extract and the solvent. Despite the loss of an appreciable proportion of this group by the bicarbonate wash, this treatment is essential in removing much of the interfering extraneous matter; phenylbutazone and oxyphenbutazone are not significantly affected. Barbiturates will also be present in this group.

Examine the extract by thin-layer chromatography using two separate silica gel G plates, and develop both with an 8:1:1 mixture of ethyl acetate: methanol: *strong ammonia solution* (System TG, p. 169). Spray the first plate with *chromic acid solution* and the second plate with *Ludy Tenger reagent*.

Details of Rf values and colours of spots are given under System TG.

DRUGS MISUSED IN SPORT

These include the anabolic steroids, the corticosteroids, non-steroidal anti-inflammatory drugs, and the diuretics. Of particular interest are the anabolic

steroids and corticosteroids; not only may synthetic analogues be misused but also testosterone or hydrocortisone. This use of a compound that is either indistinguishable, or distinguishable with difficulty, from that which is naturally produced by an individual, presents interesting analytical problems.

Anabolic Steroids

These have come into prominence in the last decade as body-building drugs. In human sport they are used, sometimes in very large quantities, in events such as weight-lifting and shot-putting. In horse-racing their use seems to be more general. They are said to improve a horse's appetite and to produce behavioural changes of a masculinising type in geldings and mares, though they may also be used in stallions. There are broadly two chemical types based upon the androstane and estrane ring systems: those with a 17 α -alkyl group which are active orally but possess hepatotoxicity, and 17-nor derivatives administered by injection.

Although steroidal oestrogens and some stilbenes reputedly possess anabolic activity and are employed in beef production, they do not appear to be used as doping agents.

Sampling is carried out at the time of competition and has enabled the misuser to switch from using a preferred synthetic anabolic steroid to testosterone in sufficient time to escape detection.

ANABOLIC STEROIDS IN HUMANS

There are several methods to indicate that testosterone has been administered to a male human. Natural testosterone production is controlled by a feedback mechanism involving the pituitary gland, and administration of testosterone will suppress the natural production of pituitary hormones such as luteinising hormone (LH) and follicle stimulating hormone (FSH).

Radioimmunoassay may be used to measure the urinary ratio of total (free plus conjugated) testosterone to LH. Testosterone is measured in nmol/litre, and LH in International Units of HMG-IR2/litre (Human Menopausal Gonadotropin 2nd International Reference Preparation). A ratio in excess of 200 is abnormal. (R. V. Brooks *et al.*, *J. Steroid Biochem.*, 1979, 77, 913-917.)

Synthetic anabolic steroids used in man may be readily detected by use of two radioimmunoassay kits which are available, one for nandrolone and one for 17 α -methyl substituted anabolic steroids (see Reagent Appendix).

In the human female, whose pituitary hormones may be suppressed by the use of oral contraceptives, the ratio of testosterone to creatinine in urine may be used. Alternatively, a method suitable for both males and females is to measure the ratio of total testosterone to epitestosterone using gas chromatography—mass spectrometry. In this method, the bis(trimethylsilyl) derivative is formed and the intensity of the molecular ions at m/z 432, under electron impact conditions for both of the steroid derivatives, is used to determine the ratio (M. Donike and J. Zimmermann, *J. Chromat.*, 1980, 202, 483-486). The internationally accepted limit for the ratio is currently 6.

Identification of Anabolic Steroids in Human Urine (R. J. Ward *et al.*, *Br. J. Sports Med.*, 1975, 9, 93-97.)

Adjust the urine sample to pH 5 by the addition of *dilute hydrochloric acid*. For each 9 volumes of urine add 1 volume of *acetate buffer (pH 5)* containing 5000 Fishman units/ml of mixed glucuronidase/sulphatase (from *Helix pomatia*), and incubate the mixture at 37° for 24 hours. Centrifuge, pour the supernatant liquid on to a column of Amberlite XAD-2 resin, wash the column with 50 ml of water, and then elute the steroids with 100 ml of ethanol. Evaporate the ethanol using a rotary film evaporator, dissolve the residue in 0.5 ml of ethanol, and add 2 ml of cyclohexane.

Pour the solution on to a column prepared with 6 g of Sephadex LH-20 (see Reagent Appendix), and

fractionate the steroids by elution with a mixture of cyclohexane and ethanol (4:1). Evaporate the solvent from the 10 to 20 ml fraction for the 19-nor steroids, or from the 30 to 40 ml fraction for 17 α -methyl substituted steroids. Dissolve the residue in 0.1 ml of dry pyridine.

To the pyridine solution add 0.1 ml of *N*-methyl-*N*-trimethylsilyltrifluoroacetamide and 0.01 ml of trimethylchlorosilane, and allow to react for 8 hours at room temperature. Remove the reagents under a stream of nitrogen and dissolve the residue in 0.1 ml of cyclohexane. Examine the solution by capillary column gas chromatography-mass spectrometry.

COLUMN. OV-1, 15 m x 0.3 mm internal diameter, connected to a mass spectrometer.

COLUMN TEMPERATURE. Programmed from 100° to 250° at 15° per minute, after the elution of the solvent.

CARRIER GAS. Helium.

ANABOLIC STEROIDS IN THE HORSE Most of the anabolic steroids used in horses are designed for parenteral use and do not have an alkyl group in position 17. The commonest of these is nandrolone. In addition, boldenone, trenbolone, and testosterone itself, may be used. Most of the urinary excretion products of these compounds are present as glucuronic acid or sulphate conjugates. The 17 α -hydroxy epimers occur mainly as glucuronic acid conjugates, whilst the 17 β compounds are mainly sulphate conjugates (Table 4).

Testosterone

Nandrolone

Boldenone

Trenbolone

Table 4. Principal urinary metabolites of anabolic steroids in the horse

Steroid	Major metabolite (glucuronic acid conjugate)	Major metabolite (sulphate conjugate)
Boldenone	17 α -Epimer	Boldenone (17 β -)
Nandrolone	5 α -Estrane-3 β ,17 α -diol	Nandrolone (17 β -)
Testosterone	5 α -Androstane-3 β ,17 α -diol	Testosterone (17 β -)
Trenbolone	17 α -Epimer	

(M C Dumasia and E. Houghton, *Xenobiotica*, 1981, 11, 323–331,

M C Dumasia *et al.*, *Biomed. Mass Spectrom.*, 1983, 10, 434–440,

M C Dumasia and E. Houghton, *Xenobiotica*, 1984, 14, 647–665.)

Although nandrolone has been regarded as exogenous, recent work has shown that it is endogenous to the sexually mature male horse (E. Houghton *et al.*, *Biomed. Mass Spectrom.*, 1984, 77, 96–99).

In those cases where a suitable antibody for radioimmunoassay is not available, a full multi-component screening procedure is necessary, and also needs to be undertaken as a confirmatory test in cases where the nature of the anabolic steroid is not known. The full analysis involves the separation of the glucuronic acid and sulphate conjugate fractions and their separate hydrolysis followed by GC-MS of their silyl or methoxime-silyl derivatives. It should be noted that the sulphatase in *Helix pomatia* will not hydrolyse the sulphate conjugates of the 17 β -hydroxy steroids, which require mild acid hydrolysis.

Identification of Anabolic Steroids in Horse Urine
Solvate a Sep-Pak C-18 cartridge (see Reagent Appendix) with 5 ml of methanol, followed by a wash with 5 ml of water. Pass 10 ml of the urine sample through the cartridge, wash with 10 ml of water, and elute with 10 ml of methanol. Evaporate the eluate at 50° in a rotary film evaporator and dissolve the residue in 1 to 2 ml of a mixture of chloroform and methanol (17:3).

Prepare a 10 mm internal diameter column of Sephadex LH-20 (see Reagent Appendix) using a slurry of 2 g of the resin in chloroform: methanol (17:3). Apply to the column the dissolved residue obtained above and elute with 30 ml of chloroform: methanol (17:3) to obtain the glucuronic acid conjugates. Carry out a second elution using 50 ml of chloroform: methanol (1:1) to obtain the sulphate conjugates. Evaporate the two eluates separately in a rotary film evaporator.

Hydrolyse the glucuronic acid conjugates by dissolving the residue in 10 ml of *acetate buffer* (pH 5), adding 5000 Fishman units of mixed glucuronidase/sulphatase (from *Helix pomatia*), and incubating at 37° for 18 hours. Extract the hydrolysate with 10 ml of ethyl acetate.

Hydrolyse the sulphate conjugates by dissolving the residue in 10 ml of ethyl acetate containing 0.1 ml of *sulphuric acid* and incubating at 37° for 18 hours. The ethyl acetate solutions from both hydrolysates are treated as follows. Wash the ethyl acetate solution with two 5-ml portions of 2M sodium hydroxide, followed by one wash with saturated sodium chloride solution, and evaporate the solutions to dryness in a rotary film evaporator.

In cases where specific anabolic steroids or their metabolites are suspected, and only 17 α -hydroxy or 17 β -hydroxy compounds are to be tested for, the separation on the Sephadex LH-20 column may be omitted. Hydrolysis is carried out on the residue from the Sep-Pak cartridge, but this will yield somewhat dirtier residues with the possibility of a reduction in sensitivity.

Thin-layer Chromatography. Dissolve the residue in chloroform and apply to a silica gel plate. At the same time apply a solution containing 1 mg/ml of 5 α -androstane-3 α ,17 β -diol in methanol as a reference solution. Develop the plate in a mobile phase consisting of ethyl acetate: chloroform (1:1). Spray the reference solution only with a 10% solution of molybdophosphoric acid in methanol. The reference substance appears as a blue-grey spot on a yellow background.

Elute the corresponding area of the chromatographed extract with methanol, separate the silica gel by centrifugation, and evaporate the methanol to dryness in a reaction tube at 60° in a stream of oxygen-free nitrogen. Testosterone, nandrolone, trenbolone, and 5 α -estrane-3 β ,17 α -diol are co-eluted with the standard. Boldenone runs below the other substances; if its presence is suspected, a reference solution should be included in the chromatography.

Gas Chromatography-Mass Spectrometry. Prepare methoxime derivatives by heating the extract from the thin-layer chromatographic plate with 100 μ l of an 8% solution of methoxyamine hydrochloride in dry pyridine at 60° for 30 minutes, and evaporate in a rotary film evaporator. Silylate by dissolving the residue in 100 μ l of chloroform, adding 100 μ l of *N,O*-bis(trimethylsilyl)acetamide and 20 μ l of trimethylchlorosilane, then seal, and heat for 2 hours at 60°. When only 5 α -estrane-3 β ,17 α -diol is to be confirmed the methoxime formation can be omitted. Prepare a 2-cm column of Sephadex LH-20 in a Pasteur pipette with a cotton wool plug, using a

slurry of the resin in chloroform: hexane (1:1). Transfer the reaction mixture to the column with two 1-ml portions of chloroform: hexane (1:1), add a further 1 ml of the solvent mixture and collect the eluate.

Evaporate the eluate at 60° in a stream of oxygen-free nitrogen, and dissolve the residue in 50 µl of undecane.

Subject this solution to capillary column gas chromatography-mass spectrometry, using the splitless injection technique, and the following chromatographic conditions. Retention indices for these anabolic steroids are given in Table 5.

COLUMN. HP-2100 fused silica, 12.5m x 0.2mm internal diameter.

COLUMN TEMPERATURE. Programmed at 20° per minute from 150° to 200°, then at 5° per minute to 260°, and maintained at this temperature for 2 minutes.

CARRIER GAS. Helium.

Table 5. Retention indices of anabolic steroids

Compound	Derivative	RI
Boldenone	Methoxime-trimethylsilyl	2709
Nandrolone	" "	2652
5 α -Estrane-3 β , 17 α -diol	Bis(trimethylsilyl)	2500
Testosterone	Methoxime-trimethylsilyl	2702, 2711*
Trenbolone	" "	2746

**syn* and *anti* isomers

(For further details see E. Houghton *et al.*, *Biomed. Mass Spectrom.*, 1978, 5, 170-173; E. Houghton and P. Teale, *ibid.*, 1981, 8, 358-361.) *Radioimmunoassay*. See W. R. Jondorf and M. S. Moss, *Xenobiotica*, 1978, 5, 197-206; D.I. Chapman *et al.*, *Eq. Vet. J.*, 1982, 14, 213-218; E. Thacker *et al.*, in *Proceedings of the 21st International Meeting of the International Association of Forensic Toxicologists*, Brighton, England, 1984.

Non-steroidal Anti-inflammatory Drugs

Aspirin and phenylbutazone have been the commonest anti-inflammatory drugs encountered, but a number of other drugs are now used for this purpose. These are mostly carboxylic acids, a few of them non-nitrogenous, and they represent a serious and intractable doping problem in the thoroughbred horse. Their use can result in erratic changes of form of a lame horse from one race to another, and hereditary weakness when breeding from unsound stock may be temporarily masked by them. Some bodies controlling activities such as show-jumping have permitted the use of these drugs. However, since 1981, the Federation Equestre Internationale has

allowed only phenylbutazone to be used, and this must not exceed a concentration of 4 µg/ml in plasma. The use of phenylbutazone is permitted almost everywhere in the USA.

QUANTIFICATION OF PHENYLBUTAZONE IN HORSE PLASMA OR URINE

(J. Taylor *et al.*, *Eq. Vet. J.*, 1981, 13, 201-203.) For plasma, acidify 2 ml with 1 ml of a 10% solution of *hydrochloric acid*. For urine, add 0.25 ml to 2 ml of water.

Extract the solution with 10 ml of a mixture of hexane:tetrahydrofuran (4:1) containing 2.5 µg/ml of hexoestrol as a reference standard. Separate the phases by centrifugation and evaporate 5 ml of the solvent layer at room temperature in an oxygen-free stream of nitrogen.

Dissolve the residue in 150 µl of tetrahydrofuran and examine by high pressure liquid chromatography using the system described below with ultraviolet detection at 240 nm, and applying 10 µl to the column.

COLUMN. Partisil PXS 10/25, 25 cm x 4.6 mm internal diameter.

ELUENT. Hexane: tetrahydrofuran (4:1) to which has been added 20 mg/litre of *acetic acid*. Calculate the content of phenylbutazone from a calibration curve prepared by repeating the procedure using appropriate reference solutions of phenylbutazone in plasma or urine.

NOTE. The Federation Equestre Internationale does not permit the use of oxyphenbutazone but allows it to be present as a metabolite of phenylbutazone. The criteria for deciding this question are not set out in the rules, but would include absolute concentrations and concentrations relative to phenylbutazone and its other metabolites.

IDENTIFICATION OF SALICYLIC ACID IN HORSE URINE

No statutory limit is prescribed for salicylic acid, but it is normally present in horse urine; it is important, therefore, to distinguish between normal concentrations and those arising from medication with aspirin or other salicylates such as topically applied methyl salicylate. Normal urine concentrations rarely exceed 10 µg/ml, but therapeutic doses of aspirin may give concentrations as much as 500 times greater. Addition of 1 ml of freshly prepared *ferric chloride solution* to 5 ml of urine will give a detectable violet colour when the concentration of salicylic acid exceeds about 100 µg/ml. A positive result should be followed

by an accurate determination of salicylic acid by high pressure liquid chromatography using the system described below with ultraviolet detection at 300 nm.

COLUMN. ODS-silica (Spherisorb-ODS, 10 μ m, 25 cm x 4.6 mm internal diameter).

ELUENT. Gradient elution with a mixture of acetonitrile and 0.05M acetic acid, commencing with 10% of acetonitrile and increasing linearly to 90% acetonitrile in 15 minutes.

FLOW RATE. 1.7 ml/min.

IDENTIFICATION OF OTHER NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IN THE HORSE

No one system of analysis is entirely satisfactory for detecting all of these compounds and a combination of techniques is essential. Many of the compounds can be detected by thin-layer chromatography using System TG (p. 169), but the results should be used only as a tentative identification. Systems TD and TF may also be used.

Gas Chromatography. This can be used to detect these compounds using 3% SE-30 on 80-100 mesh Chromosorb G (System GD, p. 194). The compounds should be converted to their methyl derivatives by heating the Acid Fraction obtained from the solvent extraction of horse urine (see above) in a sealed tube at 100° for 30 minutes with 180 μ l of iodomethane and 50 mg of potassium carbonate. Trimethylanilinium hydroxide is not recommended for methylating these compounds.

High Pressure Liquid Chromatography. Urine may yield masking compounds on the gas chromatograph, and for complete screening, high pressure liquid chromatography should be used in conjunction with gas chromatography and thin-layer chromatography. The following system is recommended using ultraviolet detection at 280 nm. Systems HD or HW (p. 214) may also be used.

System HV

COLUMN. ODS-silica (Spherisorb-ODS, 5 μ m, 20 cm x 4.6 mm internal diameter).

ELUENT. Acetonitrile:0.1M acetic acid (45:55).

Elute isocratically for 2 minutes then increase the proportion of acetonitrile by 3% per minute up to 75%, followed by isocratic elution for 6 minutes.

FLOW RATE. 1.7 ml/min.

(For further details see P. Chalmers *et al.*, in

Proceedings of the 21st International Meeting of the International Association of Forensic Toxicologists, Brighton, England, 1984.)

A list of retention times of anti-inflammatory compounds and other acidic drugs, relative to meclofenamic acid, is given in Table 6.

Table 6. Relative retention times of non-steroidal anti-inflammatory drugs in system HV

Compound	Retention time relative to meclofenamic acid
Alclofenac	0.61
Benoxaprofen	0.98
Bufexamac	*
Clonixin	0.87
Diclofenac	0.85
Diflunisal	0.77
Fenbufen	0.81
Fenclofenac	0.91
Fenoprofen	*
Feprazone	0.92
Flufenamic acid	1.00
Flunixin	0.99
Flurbiprofen	0.89
Frusemide	0.45
Ibuprofen	*
Indomethacin	0.87
Indoprofen	0.52
Ketoprofen	0.66
Meclofenamic acid	1.00
Mefenamic acid	0.95
Naproxen	0.67
Niflumic acid	0.93
Oxyphenbutazone	0.69
Phenylbutazone	0.95
Salsalate	0.69
Sulindac	0.78
Theobromine	†
Theophylline	†
Tolmetin	0.60 and 0.99

Corticosteroids

The term corticosteroids strictly applies only to the steroids of the adrenal cortex. However, it is generally used colloquially as a collective term embracing their synthetic analogues. Only the glucocorticoid steroids are important in doping because of their anti-inflammatory action, and these are abused in the same manner as their non-steroidal counterparts.

In man, hydrocortisone gives mainly 5 β metabolites, whereas 11 β -hydroxyandrostenedione, which is also secreted by the adrenal cortex, gives mainly 5 α metabolites. Thus, if hydrocortisone is administered, it would be expected to decrease the normal ratio of 5 α to 5 β metabolites. Hence, the ratio of 5 α to 5 β metabolites in the 11-oxygenated-17-oxo steroid metabolites of hydrocortisone and of 11 β -hydroxy-

androstenedione may be a reliable measure of the administration of hydrocortisone. A *radioimmunoassay* procedure for urine can be used to detect most synthetic corticosteroids as well as exogenous hydrocortisone (D.I. Chapman *et al.*, *Vet. Rec.*, 1977, 100, 447-450; M. C. Dumasia *et al.*, *J. Biochem.*, 1973, 133, 401-404).

High Pressure Liquid Chromatography High pressure liquid chromatography can be used as a screening procedure instead of radioimmunoassay, although it is less sensitive. Extract 10 ml of urine with 25 ml of methylene chloride, separate the solvent layer, and dry it over anhydrous sodium sulphate. Examine 10 µl of the extract using a silica column (Zorbax SIL, 5 µm) (System HT, p. 219).

k' Values for corticosteroids are given under System HT.

Gas Chromatography-Mass Spectrometry Negative-ion chemical ionisation mass spectrometry is the best method to identify a wide range of synthetic corticosteroids in horse urine (E. Houghton *et al.*, *Biomed. Mass Spectrom.*, 1982, 9, 459-465).

Method. Extract 10 ml of urine with 25 ml of methylene chloride, separate the solvent layer, dry over anhydrous sodium sulphate, and evaporate to dryness in a rotary film evaporator at 30° to 40°. Heat the residue with 100 µl of an 8% solution of methoxyamine hydrochloride in dry pyridine in a reaction tube at 80° for 30 minutes, add 50 µl of trimethylsilylimidazole, and heat at 80° for a further 2 hours.

Prepare a 2-cm column of Sephadex LH-20 in a Pasteur pipette with a cotton wool plug, using a slurry of the resin in chloroform: hexane (1:1). Transfer the reaction mixture to the column with two 1-ml portions of chloroform: hexane (1:1), add a further 1 ml of the solvent mixture and collect the eluate. Evaporate the eluate in a rotary film evaporator at about 30° to 40° and dissolve the residue in 100 µl of dodecane. Subject this solution to capillary column gas chromatography-mass Spectrometry using the column and injection technique described under anabolic steroids (p. 95) except that the column temperature is programmed at 20° per minute from 190° to 260°, then at 5° per minute to 280°, and maintained at this temperature for 2 minutes.

Caffeine, Theobromine, and Theophylline

These comprise the most commonly reported horse-doping agents in the United Kingdom, and the use of caffeine is very common world-wide.

Theobromine and theophylline are metabolites of caffeine in the horse (M. S. Moss, 1977), and theobromine is frequently ingested with caffeine as a result of the contamination of pelleted horse feed with cocoa husk. Theophylline may also occur as a result of administering aminophylline for respiratory problems. Caffeine appears occasionally in greyhound urine as a result of the widespread practice of giving tea prior to racing. Theobromine, theophylline, and 1,7-dimethylxanthine are all metabolites of caffeine in the horse and man but their proportions vary greatly between the species. In human sport, the upper limit on the urinary concentration of caffeine has recently been set at 15 µg/ml.

Caffeine itself is poorly extracted into ether, though yields can be improved by the addition of sodium chloride or other neutral soluble electrolytes. Chloroform is a much better extracting solvent and its use is essential if theobromine is to be extracted. Although the methylxanthines are often described as alkaloids or as weak bases, the dimethylxanthines are in fact weak acids and are best extracted from acidic solution. They are well separated by high pressure liquid chromatography (A. Aldridge *et al.*, *Clin. Pharmac. Ther.*, 1979, 25, 447-453), but for gas chromatographic analysis only caffeine can be chromatographed without derivatisation. A convenient technique for distinguishing these dimethylxanthines and the methyluric acid metabolites of caffeine is the gas chromatography-mass Spectrometry of their deuteromethyl derivatives, prepared by reaction with deuterodiazomethane, or of their deuterobutyl derivatives (E. Houghton, *Biomed. Mass Spectrom.*, 1982, 9, 103-107).

Diuretics

Diuretics, and especially frusemide, are widely used in horse racing although the reason is somewhat obscure. They are also used in weight-lifting and other competitions classified by weight. Diuretics are permitted in most of the USA. The dilution of the urine which results from their use can render detection of some other drugs more difficult.

Diuretics can be detected in urine by high pressure liquid chromatography using System HN (p. 217), or by thin-layer chromatography using silica gel G plates and ethyl acetate as the mobile phase (System TF, p. 168). A method applicable to human urine is described under Screening for Abuse of Diuretics, p. 32.

Miscellaneous Substances

ACETYLENE

The use of calcium carbide administered orally in gelatin capsules to horses has been reported in Australia. Acetylene can be detected by head-space gas chromatography of plasma.

ANTHELMINTICS

Thiabendazole, pyrantel tartrate, and phenothiazine are the commonest anthelmintics found in horses.

APOMORPHINE

This has been reported frequently in racehorses in the USA. It has a marked effect on locomotor activity in the horse. Apomorphine is one of a number of compounds which are detected by normal screening procedures only after hydrolysis with β -glucuronidase.

BENZODIAZEPINES

These may be detected in urine using the method described under Hospital Toxicology and Drug Abuse Screening, [p. 10](#).

CAMPHOR

This has the reputation of being a respiratory stimulant in horses and is thought to be usually administered by intramuscular injection. The parent compound is not detectable in horse urine. It undergoes a series of oxidations, one product of which is isoketopinic acid which is found as an acid-labile conjugate. This may be hydrolysed by heating with *hydrochloric acid* at 100° for 10 minutes. The liberated acid can be derivatised to its 2,4-dinitrophenylhydrazone and detected by thin-layer chromatography, using silica gel plates and chloroform as the mobile phase followed by a second development with a mixture of chloroform:methanol (15:1); it occurs as a yellow spot with an R_f of 20.

CHLORIBUTOL

This sedative has been found on innumerable occasions in greyhounds and occasionally in horses. Although it can be detected by the Fujiwara Test, [p. 135](#), the concentration in horse urine following its administration is extremely low, and gas chromatography should be used for confirmation (see monograph).

DIMETHYL SULPHOXIDE

This is used as a solvent for the percutaneous administration of certain drugs in the horse. It imparts an odour of rotten cabbage, probably as the result of sulphide formation.

HORDENINE

This has been found occasionally and appears to arise from the presence of sprouting barley in horse feed. It may be detected during gas chromatography of the Basic Fraction.

LUPANINE AND SPARTEINE

These alkaloids appear occasionally in horse and human urine, and may be detected during gas chromatography of the Basic Fraction. Lupins are being used increasingly as a source of dietary protein in horse feed and the compounds may therefore be expected to occur more frequently.

METHYLHYDANTOIN

This arises as a degradation product of urinary creatinine, and occurs only in urine which has aged for several days between voiding and analysis. It may be found during gas chromatography of the Basic Fraction.

4-METHYLTHIAZOL-5-YLETHANOL

This is believed to arise as a metabolite of thiamine and may indicate administration of a vitamin B₁ preparation. Thiamine is thought to have a sedative action in the horse when given in large doses. The metabolite may be detected during gas chromatography of the Basic Fraction. When it occurs the concentration of thiamine should be measured. Urinary concentrations greater than about 100 µg/ml are unusual after oral administration, but much higher concentrations may be found after parenteral administration.

PEMOLINE

This stimulant has been reported frequently in man and occasionally in horses. Although moderate concentrations of pemoline may be detected using Screen B ([p. 91](#)), for greater sensitivity the concentration of the metabolite, mandelic acid, should be determined using gas chromatography-mass spectrometry; confirmatory tests for pemoline should also be carried out since mandelic acid is a metabolite of several compounds.

PERLOLINE

This alkaloid, which is a constituent of perennial rye grass, occurs very frequently especially during the summer. It is a troublesome masking agent in ultraviolet spectrophotometry.

POLYETHYLENE GLYCOLS

These compounds, which are mixtures of condensation products of ethylene oxide and water (macrogols), are used as solvents for a variety of pharmaceutical preparations, including some ste-

roid formulations. The presence of polyethylene glycols is considered presumptive evidence of the administration of such a product and is considered to be an offence by some authorities.

Polyethylene glycols are rather poorly extracted by chloroform and not at all by ether. They are detected on paper chromatography systems by their very strong reaction with *acidified iodoplatinate solution*, and with lower sensitivity by thin-layer chromatography. A characteristic of polyethylene glycols is their persistence in several sequential chloroform extracts; extractability at any pH is strongly indicative of these compounds. If they occur in screening procedures based on thin-layer or paper chromatography, it is essential to separate them from the organic bases. This is best done by extracting the bases from the chloroform extract with 0.25M sulphuric acid and back-extracting with several portions of chloroform until the extracts are free from polyethylene glycol, as indicated by the reaction with acidified iodoplatinate solution. The acidic aqueous phase may then be made alkaline and re-extracted to obtain the basic group. The identity of the polyethylene glycols is best established by infra-red spectrophotometry following elution from paper chromatograms. They tend to streak on paper and thin-layer chromatographic systems; the lower molecular weight compounds have higher R_f values.

RESERPINE

This highly potent compound has been used on a number of occasions as a tranquilliser for horses. A dose of only 5 mg has demonstrable effects for several days. The following procedure can be used to detect reserpine in horse plasma following a dose of 1 to 2 mg. (After R. A. Sams and R. Huffman, *J. Chromat.*, 1978, 161, 410-414.)

Add 2 ml of a saturated solution of borax to 2 ml of plasma, extract with 4 ml of toluene, separate the

toluene layer, and evaporate under a stream of nitrogen at 50°. Dissolve the residue in 6 µl of methylene chloride, divide the solution into three 2-µl portions, and examine by thin-layer chromatography using silica gel G plates and the mobile phases shown in Table 7. After development, dry the plates using a hot air blower, expose them to the vapour of *acetic acid* for one hour, and examine under ultraviolet light at 350 nm; reserpine appears as a bright blue spot.

Table 7. Thin-layer chromatography of reserpine

Mobile phase	R _f
Chloroform: acetone (70:30)	15
Chloroform: methanol (95:5)	50
Butanol: water: <i>acetic acid</i> (80:20:20)	72

A radioimmunoassay for the detection of reserpine in horses has been described (E. Thacker, *Analyt. Proc.*, 1985, 22, 136-137).

NOTE. Reserpine is very strongly adsorbed on to glass surfaces and scrupulous cleaning of glassware is essential when analysing this compound.

Therapeutic Drug Monitoring

V. Marks

Drugs have always played an important part in the treatment of diseases, even when few were of proved efficacy and their mode of action was poorly understood. The introduction during the last half century of selective, potent, and potentially dangerous drugs, and the requirement by various regulatory bodies that they are efficacious, has done much to ensure that therapeutic practices that were adequate in a bygone age are no longer acceptable. In order to increase the efficacy and decrease the toxicity of drugs, dosage regimens should take into account the different ways in which different individuals absorb, metabolise, excrete, and respond to drugs. In order to achieve this, the clinician must in many cases tailor his treatment to the individual patient's requirements. Although this is not a new idea, having been practised in digitalis therapy for over two hundred years, its importance as a general principle has been slow to gain acceptance. This has been due to the lack of suitable methods for individualising drug treatment. Usually, both the therapeutic and toxic responses to a drug occur too slowly to permit adjustment of the dose to achieve optimum therapeutic effectiveness, and serious or even irreversible damage can occur because of under- or overtreatment.

It is now recognised that for some drugs (e.g. phenytoin, lithium, procainamide, and theophylline) the therapeutic response correlates better with the concentration in plasma than with the daily dose. This, together with developments in analytical technology that enable measurements to be carried out quickly on small samples of blood, has led to a rapidly developing interest in the possibility of using plasma concentrations as a guide to improving therapeutic efficacy. This chapter examines the conceptual basis of such practices, their usefulness and limitations, and discusses methods for measuring the few drugs for which it has been currently established that clinical monitoring is worthwhile. Non-compliance, i.e. the failure of patients to take their prescribed drugs, is probably the commonest cause of therapeutic failure. The use of blood or urine concentrations has been advocated as a means

of detecting and preventing non-compliance, but since the argument is applicable to all drugs it will not be dealt with further here.

Fundamental Concepts

The theoretical basis for therapeutic drug monitoring rests upon three premises. Firstly, that the therapeutic response to a particular drug correlates with its concentration in the blood rather than with the dose. This is clearly inapplicable to drugs which are either not absorbed when given orally (e.g. neomycin) or which exert their effect largely or exclusively at their site of application (e.g. topical steroids, antifungal agents, etc.). Secondly, that there exists an optimum therapeutic range within which the majority of patients experience maximum clinical benefit with minimum toxic or unpleasant side-effects. Thirdly, that by adjusting the dose and the timing of drug administration on the basis of the plasma concentration, the attainment and maintenance of the optimum therapeutic range of a drug leads to a greater patient benefit than can be achieved by the exercise of sound clinical judgement alone.

These premises have so far been established as true for extremely few drugs. In some cases, they are known to be invalid. Drugs whose effects are irreversible and/or exerted through denaturation of intracellular proteins (e.g. the monoamine-oxidase inhibitors) or by depletion of stored materials (e.g. reserpine) belong in this category.

Inherent in the rationale of therapeutic drug monitoring is the assumption that the plasma concentration of the drug reflects its concentration at the cell membrane, and that there is a high degree of correlation between them. This is not necessarily true if the blood supply to the tissue is impaired, as is often the case with poorly vascularised tissues and tumours which have outstripped their blood supply. Also, much of the drug present in the circulation, and measured as such when assays are performed on plasma, is bound to a greater or lesser extent by plasma proteins. The ratio of protein-bound to non-protein-bound drug (free drug) in the plasma is dependent on a number of factors.

The most important are the nature of the drug, its molar concentration relative to that of the individual plasma protein (generally albumin), and the presence of competing substances for binding sites (usually other drugs, but occasionally endogenous compounds). Disturbance of the ratio of protein-bound to non-protein-bound drug from the normal by any of these factors can totally invalidate the value of plasma 'total drug' concentration measurements. This occasionally happens in patients with a particular disease, e.g. uraemia, in whom plasma-phenytoin concentrations may be extremely low in the presence of unequivocal phenytoin intoxication. Another reason for disagreement between plasma-drug concentrations and the biological effects observed is the development of tolerance to the action of the drug at the cellular level as occurs with, for example, morphine and some barbiturates such as phenobarbitone. It can also occur if the cells lose the capacity to respond to the drug, as in the case of the failing heart already maximally stimulated by digoxin.

Therapeutic Response

In practice, there is no advantage in measuring the concentration of drug in the blood if its biological effect can be easily monitored. For example, it is not customary to measure the blood concentration of oral antidiabetic agents such as tolbutamide, chlorpropamide, and other sulphonylureas, since it is more pertinent and simpler to measure the blood-glucose concentration directly. Similarly, it is not often considered necessary to measure the blood concentrations of antihypertensive agents (e.g. propranolol and methyldopa) except as a test of compliance, since it is generally more informative to measure the blood pressure. Also, the control of anticoagulant therapy has long been regulated by reference to the plasma prothrombin time.

In the case of drugs such as the antibacterials, antivirals, antifungals, and antiparasitics, the therapeutic effect is achieved as the result of the differential susceptibility of the parasite and the host's own tissues to the toxic effects of the drug. For some (e.g. the penicillins), the margin between the two is so great that they can be considered as innocuous to humans, but deadly to sensitive organisms. However, with others, e.g. streptomycin, gentamicin, amikacin, and vancomycin, the difference between the concentration that is required to inhibit sensitive parasites, often referred to as the minimum inhibitory concentration, and that which

is toxic to human tissue is so small as to make their use dangerous unless controlled by regular measurements of blood concentration. The same considerations are probably true of antineoplastic agents, e.g. methotrexate and cytarabine, which behave like antibiotics and exert their beneficial effect by virtue of their differential toxicity towards neoplastic and normal tissues. At the present time, too little information is available about the clinical monitoring of this class of compound to make further discussion profitable.

Indications for Measuring Drugs in Blood

The general indications for measuring drugs in blood include the investigation of pharmacokinetics, protein binding, bioavailability, and the comparability of different drug preparations. However, there are a number of specific clinical indications which apply to a greater or lesser extent to all of the drugs for which therapeutic drug monitoring has been established as useful.

The first clinical indication for drug monitoring occurs when the administration of doses that are usually effective in susceptible conditions does not produce a favourable response. The commonest reason for this is non-compliance, but others include reduced bioavailability, non-absorption, more rapid (or slower) metabolism or elimination than normal, reduced access to the drug's site of action, and tissue or organ unresponsiveness.

The second clinical indication for measuring blood-drug concentrations is to provide a guide to the adjustment of drug dosage in order to obtain optimum effectiveness, when no simpler or more directly relevant indicator is available (e.g. phenytoin, theophylline, and gentamicin). This form of therapeutic drug monitoring is better referred to as individualisation of drug therapy.

Coupled with this, but different in concept, is the use of drug measurements to prevent the appearance of severe and irreversible adverse drug reactions when these cannot be predicted by simpler clinical methods. This indication is particularly important when there is co-existing disease (e.g. renal or hepatic failure) which so alters pharmacokinetic behaviour as to render general guidelines on drug usage inappropriate. This is true of anti-arrhythmic drugs such as lignocaine whose half-lives are greatly prolonged by poor liver perfusion. This occurs in patients who have recently suffered myocardial infarction and are the very ones most likely to be treated with drugs of this type.

A fourth reason for measuring drugs in blood is as

an aid to distinguishing between overtreatment and undertreatment when this is difficult on clinical grounds alone. Digoxin measurements are a good example of this situation, since the clinical condition of a patient who has taken an overdose may be indistinguishable from that of a patient who has been prescribed the drug but has not been taking enough. This is the realm of diagnostic biochemistry, and measurements should be made only when there are good clinical indications for them.

Finally, one of the most important indications for measuring blood-drug concentrations occurs during trials of new and established drugs, in order to assess their clinical efficacy and optimum mode of usage. During the first few months of the general release of a new drug, the measurement of blood concentrations would serve to identify those patients in the community who cannot eliminate it normally from their bodies and may, as a consequence, suffer severe or possibly fatal adverse effects.

Choice of Drugs to be Monitored

The blood concentrations of many drugs are measured in clinical laboratories, but it is only for a few that these measurements have been shown unequivocally to provide clinically useful information. This is true in distinguishing between under-dosage and overdosage (e.g. digoxin, nortriptyline), and in the adjustment of dosage (e.g. gentamicin, lithium, phenytoin, theophylline).

The features of a drug that make it likely that it will be worth monitoring are best illustrated by reference to lithium. This is almost the perfect example of a drug whose use is only ethically possible because of the ability to measure its concentration in plasma and use the information so obtained to adjust the dosage regimen.

Lithium is used extensively for the prevention of recurrences of symptoms in patients suffering from either manic depression or endogenous depression. The plasma-lithium concentration correlates well, within narrowly defined limits, with therapeutic effectiveness. Plasma concentrations below about 0.5 mmol/litre exert little protective effect against relapse; concentrations above 1.2 mmol/litre are associated with an unacceptably high incidence of side-effects, some of them potentially fatal. The measurement of lithium in plasma is simple, quick, accurate, and precise. Lithium has no metabolites and is relatively free from interference by any other substance ever likely to be present in plasma. It is not protein-bound and has a moderate to long half-

life in the body which, though entirely dependent upon renal excretory capacity, can be influenced by dietary factors such as salt content and by concurrent therapy with drugs such as chlorothiazide. The diseases for which lithium therapy is used are serious, economically important, and common. This has enabled both retrospective and prospective clinical trials to be conducted by more than one group of investigators to establish a therapeutic range. For no other drug has such a good case been established for making plasma-drug measurements a part of a drug monitoring programme.

The main drugs for which therapeutic drug monitoring has established itself as useful, are those that affect the metabolism, activity, function, or other attribute of the patient's own tissues, either by reacting with specific receptors in the cell or by interfering with the activity of one or more of its enzymes in a reversible and concentration-dependent manner. This excludes that small group of drugs which appear to bind irreversibly to proteins within the cell, and continue to exert their effects until either the cell dies or the protein to which the drug is attached is replaced by renewed synthesis. Drugs of this kind have been referred to as 'hit and run drugs' and include the alkylating agents, e.g. chlorambucil, melphalan, and cyclophosphamide, and certain enzyme inhibitors, e.g. phenelzine and tranylcypromine. However, it now seems likely that some of the drugs formerly placed in this category (e.g. amiodarone) may need to be reclassified, because more sensitive analytical methods have revealed their continued presence in the blood at extremely low concentrations throughout the period of response.

The Table on [p. 107](#) lists a number of drugs which have been the subject of drug monitoring studies. The clinical value of therapeutic drug monitoring of each of the 25 drugs listed has been classified from well-proved value to no proved value. Included in the table are some drugs which are clearly not worth monitoring but which nevertheless often are, e.g. primidone and phenobarbitone. This is often because the result is generated as a by-product of other reasonably requested assays, e.g. phenytoin, where these are performed by chromatographic techniques.

Choice of Body Fluid for Assay

Most of the developmental work on therapeutic drug monitoring has been carried out using plasma and measuring the total concentration of drug present. However, this does not reflect the concentration of

drug at the surfaces of the effector cells as well as would the concentration of the non-protein-bound drug (free drug) measured by ultrafiltration or dialysis. However, the deduction that only free drug is biologically active is unwarranted and denies the possibility that protein binding might facilitate attachment of drug to its receptors on the effector cells. In the absence of conclusive experimental data, the superiority of free over total plasma-drug measurements must still be considered conjectural. The above situation is also true of measurements carried out on saliva which often, but not invariably, provide a rough estimate of unbound drug concentration. Consequently, despite its greater availability and ease of collection, saliva has not proved to be a clinically useful fluid for therapeutic drug monitoring except in a very limited number of cases, e.g. theophylline whose secretion is relatively uninfluenced by the rate of flow of saliva.

Urine specimens may be received for analysis to check compliance. However, quantitative assays have no advantage over semiquantitative or even simple qualitative methods for this purpose. The result may be extremely difficult to interpret because urinary-drug concentrations, except in the case of alcohol, rarely bear any well-known relationship to those of blood collected at the same time.

Timing of Measurements

Because drugs are usually administered at intervals of time, their concentration in body fluids is subject to fluctuations. The magnitude of the plasma-drug concentration thus depends upon a number of variables, the most important of which are the bioavailability of the product, the frequency of dosing, and the rate of elimination. Therapeutic responses to drugs which act upon the patient's tissues usually correlate better with steady-state rather than with peak plasma-drug concentrations. Toxic effects, on the other hand, often relate more closely to peak than to steady-state plasma-drug concentrations.

When the steady-state concentration is reached, the total body burden of a drug remains more or less constant within relatively narrow limits. In this hypothetical situation there is little or no redistribution between the various body compartments. The maintenance of this ideal state implies that the drug must be administered at regular intervals in an amount equal to the amount eliminated from the body in the interval, and that this interval is long enough to permit complete absorption and distribution through the body compartments.

The steady state is achieved after the lapse of about six biological half-lives of the drug. It can be achieved more quickly, should this be considered clinically necessary, by manipulating the dosing schedule according to the pharmacokinetic behaviour of the drug and by consideration of the patient's own response characteristics. Because of the relatively long interval between altering the dose of a drug and the attainment of a new steady state, little clinical importance can be attached to blood-drug measurements made less than this interval after the last dosage adjustment. This can be as long as a week or more in the case of drugs with very long half-lives.

Once the steady state has been reached, the size and timing of fluctuations about the mean blood-drug concentration are determined by the mode of delivery, the bioavailability, and the interval between dosing, as well as by the pharmacokinetics of the drug itself. Optimum therapeutic ranges for most drugs relate to the blood concentration immediately preceding the next scheduled dose. Thus a blood sample for digoxin would be taken 6 hours after the last dose as it has a half-life of about 36 hours, whilst sodium valproate has a much shorter half-life (11 hours), and samples should be taken earlier. In the case of lithium, a strong case has been made for standardising measurements of the plasma-lithium concentration in the morning, exactly 12 hours after the last dose.

Stages in the Development of a Clinical Assay

The first, and absolutely essential, step in the development of a clinical assay is the production and validation of a suitable analytical technique. The next is to establish that the blood-drug concentration correlates with the therapeutic effectiveness and/or toxicity of the drug. Usually, this can only be achieved by a retrospective study of a large number of subjects over a long period of time, during which many analytical measurements and careful clinical observations have been made and properly documented. If a relationship between plasma concentration and effectiveness does exist, such data should permit a tentative optimum therapeutic range to be derived. During this latter stage it should be possible to establish that when blood-drug measurements are made and are used as the basis of dosage adjustment, the patients fare better than when drug dosage is adjusted empirically or on clinical response alone. The tentative optimum therapeutic

range can then be used as the basis for the third stage of development, namely, the prospective clinical trial. Unfortunately, the prospective stage of assay development has been carried out for only a handful of drugs, i.e. lithium, phenytoin, and ethosuximide.

Measurement Techniques

A variety of analytical techniques has been used for measuring the concentration of drugs in body fluids. Some suggested assay methods for therapeutic drug monitoring purposes are given in the Table below. Various published methods and commercial immunoassays are listed to allow the selection of a method according to the instrumentation available. Further methods are given in the monographs in Part 2.

Much of the present pharmacokinetic knowledge, especially that upon which the principles and practice of therapeutic drug monitoring depend, was derived from studies using *colorimetry*, *spectro-photometry*, and *spectrofluorimetry*. The first two of these techniques are relatively insensitive and susceptible to interference by other substances present in biological fluids. Their use has been virtually abandoned except for the measurement of paracetamol and salicylate in cases of suspected overdose. This susceptibility to interference is also the factor limiting the more general application of spectrofluorimetry to therapeutic drug monitoring. *Bioassay*, which is still often used for measuring antibiotics in biological fluids, is too slow, insensitive, and labour-intensive to justify its widespread application.

Thin-layer chromatography was largely responsible for the upsurge in qualitative analysis of body fluids for drugs, since it separated the drug from its metabolites and interfering compounds. However, it has proved less useful as a quantitative tool, even with the availability of high performance thin-layer chromatography plates and reliable scanning-reflectance spectrophotometers.

Gas chromatography has been the technique of choice for measuring drugs in blood and other biological fluids, although it has the disadvantages that it is relatively slow, labour-intensive, and insufficiently sensitive for many drugs. *High pressure liquid chromatography* has rapidly established itself as adaptable and readily amenable to the rapid measurement of a wide range of drugs although it may lack sensitivity. High pressure liquid chromatographic methods are generally precise and more specific than other analytical techniques.

This latter consideration is especially important in the measurement of drugs which undergo extensive metabolism, the products of which may remain in the circulation for longer than the parent compound. The method is quicker to use than gas chromatography and has a wider range of applicability. For both methods, the initial capital costs are often high, but the running costs are usually low. The growth of clinical interest in the monitoring of therapeutic drug concentrations has been greatly increased by the development and application of *immunoassay* techniques, especially those which dispense with the need for phase separation, i.e. the homogeneous immunoassays. Information on the technique of immunoassay can be found under Immunoassays (p. 148).

Kits for immunoassays are available from a number of commercial sources for measuring most of the drugs for which it has been shown to be worthwhile, as well as for a large number where it has not. Kits seldom require the use of apparatus that is not already generally available in any well-equipped clinical laboratory, though several manufacturers now market pre-programmed microprocessor-controlled instruments designed specifically for use with their own reagents. Homogeneous immunoassay techniques are generally simple, requiring only the addition to the sample of one, two, or three reagents in an orderly, timed sequence. Rarely does the sample size exceed 100 microlitres. Homogeneous immunoassay techniques are generally quick, precise, and sufficiently accurate to make them acceptable in nearly all clinical situations. Commercial reagents do not, at present, have the requisite sensitivity to enable them to be used for measuring drugs whose plasma concentration is much less than 1 ng/ml.

Where exquisite sensitivity is required it is generally still necessary to resort to the use of heterogeneous immunoassay techniques employing radio-, enzyme-, or fluorescent-labelled drugs.

Immunoassays are generally easy to automate, but this is scarcely a real advantage since the nearer the patient and the more rapidly the result can be obtained, the more clinically valuable is the drug measurement likely to be. The most serious objection to immunoassays as a measurement technique for drugs in biological fluids is their susceptibility to interference by metabolites of the drug or its analogues. This generally renders immunoassays unsuitable for use in toxicological diagnosis or in situations in which there is doubt as to the exact

nature of the drug being used. Only very rarely does it cause difficulties in therapeutic drug monitoring, since this information is generally available. Another disadvantage in the use of immunoassays occurs in cases where polypharmacy is being practised, as still often happens in the treatment of epilepsy. A separate assay must be performed for each of the drugs it is intended to measure, and it may be impossible to obtain accurate results if the drugs or their metabolites cross-react in the different immunoassays. This is where chromatographic techniques have an advantage, because a separation stage precedes quantification and allows several drugs with similar physicochemical properties to be measured together.

The combination of two different methods of separation and measurement, e.g. HPLC and immunoassay, or GC and mass spectrometry, will increase specificity but is rarely required in therapeutic drug monitoring. Such methods must, however, be used for assessing the analytical reliability of an immunoassay under varying conditions of clinical usage.

Quality Control

Quality control is essential in the performance of therapeutic drug monitoring assays because clinical decisions as to whether the dose should be increased, decreased, or left unchanged are sometimes made exclusively on the basis of the analytical result.

Most externally-organised quality control schemes have revealed that the performance of many participants is unacceptable; this is due mainly to their use of inappropriate methodologies. Other important sources of error are the use of incorrect standards and of inappropriate internal quality controls. Because of the risk of interference by other drugs and metabolites in many analytical techniques, it is vital that external quality control material should be properly prepared. For further information see under Quality Control in Clinical Analysis (p. 118).

Interpretation of Results

It is not uncommon to endow blood-drug measurements with far more predictive or diagnostic importance than they deserve. Apart from analytical errors due to the use of imprecise or inaccurate measurement procedures, the main cause of error in therapeutic drug monitoring is misinterpretation of the data. The commonest reason for this is failure to appreciate the importance of correct timing of specimen collection in relation to dosing and changes

in dosing regimen. Another cause of error is to pay too little attention to the effect of other chemical and biological variables upon the physiological and pharmacological significance of a single drug measurement. For example, the concentration of potassium in the plasma is a major determinant of whether a given plasma-digoxin concentration is cardiotoxic. Metabolites which are themselves pharmacologically active should always be considered since the drug: metabolite ratio in the plasma will be quite different at the start of therapy and at steady state (e.g. primidone/phenobarbitone and amitriptyline/nortriptyline). The optimum therapeutic range of one drug in the presence of another with similar biological properties (e.g. anticonvulsants) has rarely been investigated. It is generally assumed to be the same as when the drug in question is given alone. Plasma concentrations commonly associated with optimum therapeutic response for drugs given alone are given in the Table (below) and further information will be found in the monographs for individual drugs.

Analytical technology is no longer the limiting factor to the extension of therapeutic drug monitoring. Instead it is the enormous amount of work that must be put into undertaking retrospective and prospective trials in order to ascertain the optimum therapeutic blood or plasma concentration. Undoubtedly, optimum therapeutic ranges will be established for drugs which are currently available and for those still to be developed. Drugs that are used for the treatment of neoplastic disease and those given prophylactically for relapsing or periodic diseases such as migraine and many psychiatric disorders are especially likely to be improved by our ability to monitor them.

Table. Drugs subjected to therapeutic drug monitoring

Drug	Comments	Suggested assay methods†	Plasma concentrations associated with optimum therapeutic response	Clinical value of therapeutic drug monitoring‡
Amikacin	Plasma concentration must exceed the minimum inhibitory concentration but cannot be accurately predicted from the dose. Toxic effects of overdose are serious. Monitoring is essential to avoid undertreatment and ensure safety.	1. Homogeneous immunoassay* 2. HPLC—J. P. Anhalt and S. D. Brown, <i>Clin. Chem.</i> , 1978, 24, 1940-1947. 3. Bioassay—J. M. Broughall, Aminoglycosides, in <i>Laboratory Methods in Antimicrobial Chemotherapy</i> , D. S. Reeves <i>et al.</i> (Ed.), Edinburgh, Churchill Livingstone, 1978, pp. 194-207.	Peak, 15-25 µg/ml Trough, 4-6 µg/ml	+++
Amitriptyline	Large genetic differences in rate of metabolism; concentrations of drug and metabolite (nortriptyline) cannot be predicted from dosage. Evidence for correlation between plasma concentrations and therapeutic response is mainly negative.	1. HPLC—System HF. 2. GC—S. Dawling and R. A. Braithwaite, <i>J. Chromat.</i> , 1978, 146; <i>Biomed. Appl.</i> , 3, 449-456. 3. Radioimmunoassay—G. Mould <i>et al.</i> , <i>Ann. clin. Biochem.</i> , 1978, 15, 221-225.	Steady-state, 0.1-0.2 µg/ml	±
Carbamazepine	Retrospective studies suggest linear correlation between sum of plasma carbamazepine and carbamazepine-10,11-epoxide and therapeutic effect.	1. Homogeneous immunoassay* 2. HPLC—J. A. Christofides and D. E. Fry, <i>Clin. Chem.</i> , 1980, 26, 499-501.	Steady-state, 4-12 µg/ml	++
Chlorpromazine	Poor response to treatment may be due to impaired absorption, rapid degradation, or insensitivity to the drug. Plasma concentrations can not be predicted from dose.	1. HPLC—J. K. Cooper <i>et al.</i> , <i>J. pharm. Sci.</i> , 1983, 72, 1259-1262. 2. GC—D. N. Bailey and J. J. Guba, <i>Clin. Chem.</i> , 1979, 25, 1211-1215. 3. Radioimmunoassay—K. K. Midha <i>et al.</i> , <i>Clin. Chem.</i> , 1979, 25, 166-168.	Considerable variation	±
Clonazepam	Correlation between plasma concentration and clinical efficacy not established. Effectiveness decreases with time despite constancy of plasma concentration.	1. HPLC—W. Shaw <i>et al.</i> , <i>J. analyt. Toxicol.</i> , 1983, 7, 119-122. 2. GC—A. G. de Boer <i>et al.</i> , <i>J. Chromat.</i> , 1978, 145; <i>Biomed. Appl.</i> , 2, 105-114.	Steady-state, 0.02-0.07 µg/ml	±

†Further methods may be found in individual monographs in Part 2

+++ Well-proved value

++ Proved value

± No proved value

<i>Drug</i>	<i>Comments</i>	<i>Suggested assay methods†</i>	<i>Plasma concentrations associated with optimum therapeutic response</i>	<i>Clinical value of therapeutic drug monitoring‡</i>
Diazepam	A well-defined therapeutic range has not been established; development of tolerance to side-effects is common.	1. HPLC—V. A. Raisys <i>et al.</i> , <i>J. Chromat.</i> , 1980, 183; <i>Biomed. Appl.</i> , 9, 441–448. 2. GC—J. L. Valentine, <i>Analyt. Lett. (Part B)</i> , 1982, 15, 1665–1683.	Steady-state, 0.1–2.5 µg/ml	±
Digitoxin	Symptoms of overtreatment may be difficult to distinguish from those of undertreatment unless plasma concentrations are measured. No evidence that clinical response is improved by adjusting plasma concentration to optimum therapeutic range in the absence of symptoms.	Radioimmunoassay*	Steady-state, 0.01–0.03 µg/ml	+++
Digoxin	As for digitoxin. Low plasma-potassium increases digoxin toxicity which may occur at therapeutic concentrations.	Immunoassay*	Steady-state, 0.001–0.0025 µg/ml	+++
Disopyramide	Retrospective studies suggest that plasma concentrations may correlate with clinical effect, but the evidence is weak.	1. Homogeneous immunoassay* 2. HPLC—C. Charette <i>et al.</i> , <i>J. Chromat.</i> , 1983, 274; <i>Biomed. Appl.</i> , 25, 219–230.	Steady-state, 2–5 µg/ml	++
Ethosuximide	Retrospective studies and prospective studies reveal good correlation between plasma concentration and therapeutic response. Main use of monitoring is in patients who have failed to respond to conventional doses without side-effects.	1. Homogeneous immunoassay* 2. HPLC—as for Carbamazepine. 3. GC—Supelco Inc. <i>Bull.</i> 779, 1979.	Steady-state, 40–100 µg/ml	+++
Gentamicin	Plasma concentration must exceed the minimum inhibitory concentration but cannot be accurately predicted from the dose. Toxic effects of overdose are serious. Retrospective studies suggest that toxic effects correlate better with high trough than with high peak concentrations.	1. Homogeneous immunoassay* 2. HPLC, Bioassay—as for Amikacin.	Peak, 4–12 µg/ml Trough, < 2 µg/ml	+++
Imipramine	Plasma concentrations correlate positively with clinical improvement but cannot be predicted from dose because of large genetic differences in metabolism.	HPLC, GC—as for Amitriptyline.	Variable, > 0.1 µg/ml (imipramine + desipramine)	++
Kanamycin	As for Amikacin	1. Radioimmunoassay* 2. Bioassay—as for Amikacin.	Peak, 20–25 µg/ml Trough, 4–6 µg/ml	+++
Lignocaine	Retrospective studies suggest that toxic effects are common at plasma concentrations over 6 µg/ml. Concentrations below 2 µg/ml may be ineffective. Concentrations can not be predicted from dose.	1. Homogeneous immunoassay* 2. HPLC—R. Lindberg <i>et al.</i> , <i>Clin. Chem.</i> , 1983, 29, 1572–1573.	2–5 µg/ml	++

<i>Drug</i>	<i>Comments</i>	<i>Suggested assay methods†</i>	<i>Plasma concentrations associated with optimum therapeutic response</i>	<i>Clinical value of therapeutic drug monitoring‡</i>
Lithium	Extensive retrospective and prospective studies have confirmed the value of regulating lithium dosage to maintain plasma concentrations within narrow and well-defined limits. Relapses are common at high plasma concentrations.	1. Emission flame photometry—A. L. Levi and E. M. Katz, <i>Clin. Chem.</i> , 1970, 16, 840–842. 2. Emission flame photometry—R. Robertson <i>et al.</i> , <i>Clinica chim. Acta</i> , 1973, 45, 25–31.	0.5–1.2 mmol/litre, 12 hours after the last dose	+++
Methotrexate	If high plasma concentrations are maintained for more than 24–48 hours, irreversible bone marrow failure may occur. Toxicity from high blood concentrations can be prevented by administration of antidote (folinic acid) any time before 48 hours after injection.	1. Homogeneous immunoassay* 2. HPLC—G. J. Lawson <i>et al.</i> , <i>J. Chromat.</i> , 1981, 223; <i>Biomed. Appl.</i> , 12, 225–231. 3. Radioimmunoassay—G. W. Aherne <i>et al.</i> , <i>Br. J. Cancer</i> , 1977, 36, 608–617.	Toxic effects common when concentration > 4.5 µg/ml at 24 hours or > 0.45 µg/ml at 48 hours after injection; folinic acid rescue is indicated.	++ (acute studies)
Nortriptyline	Large genetic differences in the rate of metabolism preclude reliable estimation of steady-state concentrations from dose. Good, but not undisputed evidence, that high as well as low concentrations are associated with failure to respond. Therapeutic response shows a curvilinear relationship to plasma concentration.	HPLC, GC, Radioimmunoassay—as for Amitriptyline.	Steady-state, 0.05–0.15 µg/ml	++
Phenobarbitone	Plasma concentrations relate to dosage but not to therapeutic response.	1. Homogeneous immunoassay* 2. HPLC—as for Carbamazepine. 3. GC—as for Ethosuximide.	Steady-state, 2–30 µg/ml	±
Phenytoin	Retrospective and prospective studies reveal a much better correlation between therapeutic response and plasma concentration than with the dose.	1. Homogeneous immunoassay* 2. HPLC—as for Carbamazepine. 3. GC—as for Ethosuximide.	Steady-state, 10–20 µg/ml	+++
Primidone	Metabolised to phenobarbitone and relative plasma concentrations of the two substances change rapidly due to the difference in half-lives. There is no evidence that monitoring the plasma concentration can improve therapeutic response.	1. HPLC—as for Carbamazepine. 2. GC—as for Ethosuximide.	Steady-state, 5–12 µg/ml	±
Procainamide	About 40% of a dose is metabolised to acecainide which accumulates in the blood. Retrospective and prospective studies reveal that therapeutic response correlates better with the plasma concentration of procainamide or of acecainide, than with the dose.	1. Homogeneous immunoassay* 2. HPLC—K. Carr <i>et al.</i> , <i>J. Chromat.</i> , 1976, 129, 363–369.	Steady-state, 4–10 µg/ml	+++

<i>Drug</i>	<i>Comments</i>	<i>Suggested assay methods†</i>	<i>Plasma concentrations associated with optimum therapeutic response</i>	<i>Clinical value of therapeutic drug monitoring‡</i>
Propranolol	No good evidence that monitoring the plasma concentration improves therapeutic management. Measurement may be used in test for bioavailability when investigating failure to respond.	1. HPLC—R. L. Nation <i>et al.</i> , <i>J. Chromat.</i> , 1978, 145; <i>Biomed. Appl.</i> , 2, 429–436. 2. GC—R. E. Kates and C. L. Jones, <i>J. pharm. Sci.</i> , 1977, 66, 1490–1492. 3. Radioimmunoassay—G. P. Mould <i>et al.</i> , <i>Biopharm. Drug Disp.</i> , 1981, 2, 49–57.	Steady-state, 0.05–1 µg/ml (variable)	±
Theophylline	Retrospective and prospective studies suggest that improved therapeutic effect is achieved by dose adjustment to achieve optimum plasma concentration rather than by adjustments made according to symptoms.	1. Homogeneous immunoassay* 2. HPLC—S. J. Soldin and J. G. Hill, <i>Clin. Biochem.</i> , 1977, 10, 74–77. 3. GC—H. A. Schwertner, <i>Clin. Chem.</i> , 1979, 25, 212–214.	Steady-state 10–15 µg/ml Toxicity is common above 30 µg/ml	+ + +
Tobramycin	As for Amikacin	1. Homogeneous immunoassay* 2. HPLC, Bioassay—as for Amikacin.	Peak, 4–10 µg/ml Trough, < 2 µg/ml	+ + +
Valproic acid	No clear evidence of correlation between plasma concentration and therapeutic response.	1. Homogeneous immunoassay* 2. GC—as for Ethosuximide.	40–100 µg/ml	±

Samples and Sampling

P. A. Toseland

The selection of the correct samples for analysis and their preservation are prerequisites in the investigation of poisoning. Detailed instructions should be given to those who provide the samples so that the integrity of the sample is constantly maintained. The correct labelling of the samples and their transport and storage should all be part of these instructions to ensure that the analyst obtains the right samples in the right condition before he starts his analysis. An appreciation of how drugs may decompose and how contaminants may be introduced is also important, and all these factors are introduced below together with examples of drugs which pose special problems.

COLLECTION

The tissue samples taken for analysis should always be chosen bearing in mind the availability of particular samples and the disposition of the drug or poison concerned. Blood and urine samples are the most usual in clinical cases and to detect doping in athletes; in fatal cases, the pathologist can choose any sample although urine and stomach contents may not always be available. It is essential that all samples are adequately labelled and preserved before being transported to the laboratory, and that as much information as possible surrounding the case is sent to the analyst before he starts his analysis. Labels should include the person's name, the sample identity, the date and time it was taken, etc. Questionnaires of the type used in forensic science laboratories (see [p. 39](#)) are ideal and will ensure that analyses are efficiently carried out on the right samples for the right drugs. Any other information, e.g. pathologist's autopsy report or warnings of a hepatitis carrier should also be sent to the laboratory. The samples most often used are: stomach contents, blood, urine, liver, bile, brain, and kidneys. The requirements for each tissue are given below.

Stomach Contents

The stomach contents (all, however small), stomach washings, vomit, and vomit on clothing should always be submitted. If only a part of the total

stomach washings is sent, then a note of the original total volume should be made. Each sample should be packaged separately, preferably in 1-litre plastic buckets.

These samples are essential for use in general screening procedures. Whole capsules or tablets are often present and can be easily recognised. Moreover, the stomach will normally contain the highest concentration of the drug after an oral dose.

A negative result in the screening procedure may indicate that the drug was not taken orally, but it may have been injected. In some cases of smuggling, drugs may be hidden in flexible packages in the rectum of individuals or swallowed. However, if the packaging is damaged, the drug may escape and be absorbed, which can lead to fatal consequences. Conversely, some basic drugs can be secreted into the gastric juices from the blood after an injection so that the detection of a low concentration of such a drug in the stomach contents does not necessarily mean that the drug was taken by mouth.

Blood

This is the most useful sample for identifying drugs and for quantitative analyses. Drug and metabolite concentrations in blood are most useful for the interpretation of the toxicological significance of the data by comparison with previously reported blood concentrations corresponding to therapeutic, toxic, and fatal conditions (see [p. 294](#)).

Two samples of blood are needed as a minimum requirement in postmortem cases. One sample is of at least 30ml, unpreserved, from an identified source in the body, e.g. femoral vein. Fluid scooped from a body cavity must not be used instead. The second sample is 2 to 5 ml preserved with at least 1% of sodium fluoride, and is primarily for alcohol analysis. Blood samples should be thoroughly mixed with the preservative to ensure that it has all dissolved—a quick shake will not do.

The addition of preservative will not ensure a valid measurement of the original alcohol concentration, but it prevents degradation from proceeding fur-

ther. Thus, the concentration found must be regarded as a minimum.

Samples of free-flowing blood should always be taken, i.e. without the application of a great deal of pressure, or tissue fluid will also be collected which may have a very different drug concentration from that in blood. For example, in a death due to a suspected drug overdose, a sample of free-flowing blood was collected from a femoral vein and found to contain 1.4 µg/ml of amitriptyline and 0.3 µg/ml of nortriptyline (the major metabolite of amitriptyline). However, a second postmortem examination was made later when blood was taken from the same site as the first sample, but with the application of a great deal of pressure in order to obtain sufficient sample. The analysis of this sample gave blood concentrations of 2.4 µg/ml of amitriptyline and 1.1 µg/ml of nortriptyline and all these results were later confirmed by a second laboratory using different assay techniques. Although the relatively high blood concentrations of both drugs and the high amitriptyline: nortriptyline ratio in both blood samples indicated an acute amitriptyline overdose, the differences between the samples shows how the inclusion of tissue fluids in a sample thought only to be blood can cause problems. This effect will always be seen with drugs that are bound to tissues rather than to the proteins in blood.

Blood is a good sample to use in cases of poisoning by gases or volatile compounds provided that it is stored in an airtight container. In a case of fatal nitrous oxide poisoning, the presence of the gas could be demonstrated by head-space gas chromatography even after storage for several weeks at 4°. This is in contrast to the whole lung sample which was stored in several layers of polythene, yet analysis failed to reveal any trace of the nitrous oxide. The use of containers made of a material impervious to the passage of gases is an obvious necessity; in this respect glass containers are best, provided that they have adequate seals (e.g. a PTFE liner).

DISTRIBUTION OF DRUGS IN THE BLOOD

Plasma or serum samples are usually used in clinical analysis because these samples contain fewer interfering substances than whole blood. The vast majority of therapeutic concentrations of drugs reported in the literature are given for either plasma or serum for this reason. However, drugs are usually distributed between erythrocytes and plasma, the ratio varying according to the drug. For this reason,

plasma should be separated from the erythrocytes as soon as possible after the anticoagulant has been added to ensure that haemolysis of the erythrocytes does not interfere with the analysis. For example, the concentration of chlorthalidone in erythrocytes is about 40 times that in the plasma, and even 1% of haemolysis (which cannot easily be seen) will increase the apparent plasma concentration by 25%. The plasma: erythrocyte ratio can be altered by contaminants in the blood sample. For example, samples collected in an old type of Vacutainer tube leached the plasticiser tris(2-butoxyethyl) phosphate from the rubber. This plasticiser has the ability to displace basic drugs from their binding sites on α_1 -acid glycoprotein, which may result in their redistribution into the erythrocytes, depending on the ability of the drug to bind with erythrocytes.

Another feature of the plasma: erythrocyte ratio is the time taken to reach equilibrium. For some drugs, changes in equilibrium may be very quick (a matter of seconds), but for others it may take hours. If terbutaline is added to a sample of whole blood, the free: bound fractions in plasma take seconds to come to equilibrium, but to achieve equilibrium between plasma and erythrocytes can take 8 hours mixing at room temperature. This is an important consideration when spiking blood samples for use as standards which may later have the plasma separated.

The handling of samples of plasma where the free: bound ratio is to be determined is particularly important. With drugs that are highly bound, e.g. phenytoin, 10% higher plasma concentrations can be observed if the sample of blood is equilibrated and centrifuged at 4° rather than at 20°. This is due to the increased binding capacity of plasma proteins at lower temperatures, whilst the binding by the erythrocytes is hardly affected by changes in temperature.

Much of the above also applies to the production of serum samples from whole blood. This should be carried out as quickly as possible in order to prevent any effects due to the lysis of the blood clot.

Whole blood is the sample of choice when trying to detect the presence of a drug in the blood. This ensures that drugs that are concentrated in the erythrocytes or bound to proteins are present in the sample to be analysed. Samples from postmortem examinations are often haemolysed and putrefied, but are the only samples that can be obtained. However, postmortem blood does sometimes separate on standing, and any portion of the sample

taken from near the surface may be rich in plasma. The samples should, therefore, be thoroughly mixed to form a homogeneous mixture before a portion is taken for analysis. Ultrasonication for 15 to 30 seconds can be used to disrupt clots of blood when necessary.

Urine

All the available urine should be taken and preserved with sodium fluoride or sodium azide. Phenylmercuric nitrate should not be used because it interferes in immunoassays and in some gas chromatographic methods. The great advantages of using urine are that the concentration of a drug may be about 100 times that in the blood, and that it is free from protein with a consequent low background of interference. Urine has the disadvantage that some drugs are excreted almost entirely as metabolites by this route, e.g. Δ^9 -tetrahydrocannabinol and most of the benzodiazepines, so that proving the presence of a particular drug will require the analysis of another fluid or tissue. Also, if death takes place quickly, e.g. from an injected narcotic analgesic or from the inhalation of hydrogen cyanide, then little or none of the drug reaches the urine.

In spite of these disadvantages, urine is still the sample of choice for the detection of doping in athletes because it is easily obtained in reasonably large quantities, and generally contains detectable concentrations of drugs that are given in therapeutic doses.

Liver

Drugs tend to be present in higher concentrations in the liver than in the blood and this, linked with its large size, makes it a very useful sample in postmortem examinations. Liver has been the most important sample for detecting drugs in forensic toxicology cases for the above reasons, but its use is now declining because of the improved sensitivity of the analytical methods used. However, it is particularly useful in cases involving decomposed or exhumed bodies where blood samples are difficult to obtain. A 250-g sample in a 500-ml plastic container is usually sufficient for most purposes. It is essential that the gall bladder is tied off before the sample is taken so that the liver is not contaminated with bile.

Bile

The gall bladder should be tied off and submitted as

a separate item. Bile is particularly useful in deaths due to morphine-like compounds because it has such a high concentration of the glucuronides of these drugs.

Brain

This is particularly useful when investigating deaths due to solvent abuse, e.g. toluene or chloroform, because of the high concentrations that these substances attain in the brain and because they are retained after death. This is also true of poisonings due to cyanide. Because the brain is resistant to postmortem putrefaction, samples are very useful for drug analysis when the body has not been found for some days after death.

Lung

Samples of lung are useful where the method of administration of the drug is by inhalation. This is true whether it is a gas such as nitrous oxide, a volatile material such as a solvent (e.g. toluene), or a powder (e.g. cocaine).

Kidney

If heavy metal poisoning is suspected, the kidneys often show histological damage due to the metal, and also the metals causing the damage tend to concentrate in the kidneys. If the metal poisoning is suspected of being a chronic condition, then samples of the hair (with intact roots) and bone should also be submitted to the laboratory.

Injection Sites

If the route of administration is suspected to be intramuscular injection, e.g. in insulin overdose, a 10-cm cube of muscle from the injection site should be taken as well as a control sample of the same size from a similar but uninjected part of the body. Smaller samples should be taken if the injection site is nearer the surface, e.g. as in subcutaneous injections.

Other Tissues

Where a body is severely decomposed, the actual concentration of a drug at the time of death may be difficult to ascertain because of its decomposition by chemical or biological means. In these cases, samples of cerebrospinal fluid and vitreous humour may aid the analyst because these fluids do not have direct blood supplies associated with them and are therefore free from enzymes and the likelihood of microbial contamination.

Although the above gives an outline of what is required, there should always be close liaison between those providing the samples and the analyst. The standing rule for pathologists and clinicians when sending samples must be 'if in doubt, contact the laboratory'.

Containers

Disposable containers should be used whenever possible to reduce the possibility of contamination. Liquid samples (blood, urine, and bile) are best placed in glass containers which are sealed with a liner that is impervious to the sample (e.g. a PTFE liner). Liners made of rubber and similar materials should be avoided since they may absorb drugs or contribute contaminants (e.g. plasticisers) to the sample. Glass may need to be silanised when low concentrations (< 10 ng/ml) of drugs are present to avoid adsorption onto the walls.

Plastic containers are useful for solid samples (e.g. liver), since the drug will not come into contact with the walls of the container. The container size should be chosen for each sample such that the container is full, so that loss of volatile components or oxidation of the drug by atmospheric oxygen is reduced to a minimum. Lids should always be airtight and the container must be fully labelled. Each container should be placed in a polythene bag which is then sealed for further security.

When all the samples from one individual are ready, they are best packed in a cardboard box for the protection of the containers, and then placed in a polythene bag to ensure that the box does not get wet during transit to the laboratory. Relevant hazard warning labels should always be placed on the bag. At no time during the sampling procedure should there be any eating, drinking, or smoking.

STORAGE

A drug which is present in a biological sample may decompose during storage and may not be detected when the sample is analysed. In clinical situations, the drug being taken is known and if the drug is not detected it is normally assumed that the drug is not being taken or that it has decomposed. However, the situation is less straightforward in cases where the identity of the drug is not known, or if it is not certain whether a drug was present in the first place.

Examples of drugs which have been found to decompose during the storage of samples of blood or liver at 4° are clonazepam, cocaine, isoniazid, lysergide, methadone, methylphenidate, morphine, nitrazepam, paracetamol, procaine, and triazolam.

A sample containing cyanide was found to contain much lower concentrations after storage at -16° . In all these cases, the drug was known to have been taken or was measured in fresh postmortem samples. At therapeutic blood concentrations, nitrazepam appears to decompose in samples at a rate of approximately 6% per day at ambient temperature. Other benzodiazepines do not appear to be as unstable. Both nitrazepam and clonazepam appear to be more unstable in blood than in aqueous solution, indicating that the decomposition is enzymatic rather than chemical. The decomposition may be reduced by adding 1% sodium fluoride to the sample. The instability of isoniazid in blood is not surprising in view of its structural similarity to endogenous compounds such as nicotinamide. Factors that must be considered in order to reduce chemical decomposition and putrefaction processes in stored samples are discussed below.

LIGHT

Drugs such as ergot alkaloids and the phenothiazines are photolabile. When present in a solid such as a sample of liver, or in an opaque medium such as blood, the degree of decomposition is reduced. Nevertheless, samples should always be stored protected from light, and the analysis should be carried out away from bright sunlight. Samples of urine and of aqueous standards should be treated with special care, and the containers should preferably be covered with aluminium foil during analysis. For drugs which are extremely photolabile (e.g. lysergide) the analyses are best carried out in a photographic dark room.

OXIDATION

When drugs are known to be easily oxidised, e.g. catecholamines such as adrenaline, all containers should be full and tightly sealed to exclude atmospheric oxygen. In addition, antioxidants such as ascorbic acid or sodium metabisulphite (1% w/v) can be used to remove oxygen from solution. However, these reducing agents can reduce *N-oxide* metabolites in urine back to the parent amines, e.g. in phenothiazines, thioxanthenes, tricyclic antidepressants, and some antihistamines. Drugs which are phenolic (e.g. paracetamol and morphine) are easily oxidised at 4° . Drugs containing sulphur groups can be oxidised *in vitro* in alkaline solution. Thus, thiopentone can be converted to pentobarb-itone whilst it is being back-extracted from an organic solvent into an aqueous alkaline medium. In addition, thiopentone can be oxidised on standing at room

temperature in organic or aqueous solution.

Ion concentration is important in oxidative processes because the metal ions can act as catalysts. The effects of ions in urine can be reduced by the addition of a protein such as bovine serum albumin. Solutions of some labile drugs are more stable in plasma than the same concentration in water. The decomposition of chlorambucil in urine increases with the concentration of chloride ion.

HYDROLYSIS

Every toxicologist who has had to deal with a case of suspected cocaine administration is well aware of the problems associated with esterase activity. The measurement of cocaine in blood by gas chromatography using alkali flame ionisation detection is a relatively simple exercise if the analysis is made shortly after the suspected consumption of cocaine. However, searching for the compound as an unknown is an entirely different proposition. The esterase activity in blood is high and cocaine is soon hydrolysed via the ester grouping. Similarly, any attempt to extract cocaine from an alkaline solution with a pH greater than 8 will have the same effect. Many compounds other than local anaesthetics are also esters and can be hydrolysed by storage of the sample at room temperature or during an extraction procedure. Methylphenidate is a compound with similar characteristics as is the narcotic diphenoxylate which is hydrolysed to diphenoxyl acid (a compound with potency equal to the parent). The use of a high concentration of sodium fluoride (at least 1 %) is recommended to counteract this esterase activity. The hydrolysis of esters may also be slowed by reducing the pH of the sample to below 4. Two further examples of esters are diamorphine and aspirin. Diamorphine is seldom detected in blood as it is rapidly hydrolysed to 6-monoacetylmorphine and morphine; the monoacetyl derivative is also rarely detected. Similarly, aspirin is rapidly deacetylated in the stomach to salicylic acid. By contrast, drugs such as the sulphonamides and procainamide are metabolised in the liver by acetylation. These amide drugs, although subject to hydrolysis, are not decomposed as easily in blood as are esters.

TEMPERATURE

It is often assumed that the freezing of biological samples is the ideal method for the preservation of drugs. This may be so for many compounds, but there are some notable exceptions, particularly easily

oxidised compounds, such as phenothiazines. For example, if plasma containing chlorpromazine is frozen, stored at -20° and thawed, the compound is recovered intact. However, if the same process is applied to a blood sample obtained from a case of chlorpromazine ingestion, then the actual plasma concentration of the parent drug is doubled during the freezing and thawing cycle due to the reduction of sulphoxide and *N*-oxide metabolites back to the parent compound. Similarly, measurement of the drug after 18 days storage at 4° also reveals an increase in the plasma-chlorpromazine concentration.

In general, it is best to store samples that will be analysed within a few days at 4° . Those that are to be stored longer should be stored at -20° , but only thawed once before analysis. For very long-term storage, freeze-drying should be considered, especially for samples that are used for standard solutions or quality assurance standards.

Biological Decomposition

The hydrolysis of esters by esterases in the blood has been considered above, but even more important is the process of putrefaction caused by microorganisms. Not only will drugs be destroyed by the activity of these micro-organisms, but compounds such as alcohol, hydrogen sulphide, and hydrogen cyanide can be produced, thus confusing the interpretation of analytical results.

It may be necessary to differentiate between antemortem and postmortem production of alcohol in a decomposed body. Little information can be obtained from the analysis of only a single sample of blood. Samples should be taken from several different sites, as well as from the right and left chambers of the heart. These samples should each be divided into two parts, one portion being stored without a preservative and the other preserved with 1% sodium fluoride. If the unpreserved and preserved samples contain different concentrations of alcohol, this is due to the continued destruction or production of alcohol by micro-organisms in the blood. If the results of the analyses are the same, then the decomposition or production of alcohol has either not occurred or has ceased.

Foodstuffs in the stomach of a corpse can ferment and produce alcohol, and this alcohol can diffuse into the tissues close to the gastro-intestinal tract. The overwhelming odour of fermentation on opening the stomach can lead to the assumption that large amounts of alcohol were consumed before

death, but this is a most unreliable indication of the quantity of alcohol consumed.

Low concentrations of alcohol can be found after death if ethyl acetate has been inhaled, because ethyl acetate is rapidly broken down by the body esterases to produce alcohol and acetic acid.

It is unfortunate that standard forensic pathology textbooks still speak of the fact that glucose is converted to alcohol after death. In reality the glucose content of an unpreserved sample of blood disappears within a few hours, whereas alcohol production after death requires a minimum of several days and some bacterial presence. Samples of blood for the determination of glucose should not be stored in the normal hospital containers for blood glucose as they only provide a final concentration of 0.1% sodium fluoride in a full tube. The use of 1% is recommended as a universal preservative.

Cyanide can cause poisoning by mouth or by inhalation. It is lost from the blood very quickly on storage so that a low concentration in blood which is a few days old and from a fatal case of poisoning is difficult to interpret. For example, a case of near-fatal overdosage gave a cyanide concentration of 1.4 µg/ml in blood 2 days after the ingestion of the dose, whereas a heavy smoker had a blood-cyanide concentration of 1.6 µg/ml, and a patient receiving a high therapeutic dose of sodium nitroprusside had a concentration of 6.8 µg/ml, the latter two samples having been analysed without delay. The best sample for the analysis of cyanide from a body which has decomposed is a sample from the middle of the brain. Oral cyanide poisoning may be diagnosed by the presence of milligram amounts of cyanide in the stomach, which differentiates it from cyanide formed on smoking or from sodium nitroprusside given by injection.

Preservatives

Reference has already been made to the preservation of biological samples during storage. However, it is worth repeating that the ideal preservatives are either sodium azide (0.1% w/v) or sodium fluoride (1% w/v) with the possible inclusion of potassium oxalate (0.5% w/v) if an anticoagulant is required. Unpreserved blood samples will always be required if investigations into cases of azide, fluoride, or oxalate poisoning are made. In addition, a sample without oxalate is required to investigate delayed deaths due to ethylene glycol poisoning.

Embalming fluids are very good preservatives of dead bodies, but cause considerable interference

with analyses other than those for metals and anions. Samples should therefore be taken from the body prior to the embalming process and preserved separately.

CONTAMINANTS

Contamination can arise from compounds produced during the putrefaction of tissues as well as from the containers themselves. The former can be reduced by correct preservation and storage conditions whilst the latter can be reduced by the correct choice of container. Also to be considered are contaminants present in the drugs themselves, since they are not usually 100% pure.

Interferences Caused by Putrefaction

The classic case is phenethylamine produced in a sample that has been inadequately preserved and stored. This compound always gives a very weak (dirty brown) iodoplatinate reaction on a thin-layer chromatographic plate and should be immediately recognisable to most experienced forensic toxicologists. The same poor and indistinct reactions are given in thin-layer chromatography by tyramine and tryptamine which are also produced during the decomposition of tissues.

Contaminants from Containers

Phthalate plasticisers can be leached from plastic containers or from the rubber closures of glass containers as well as deriving from the solvents used for extraction. Their presence in a sample produces an interfering peak on a gas chromatogram when using a flame ionisation or an electron capture detector (see Fig. 1, p. 185). A second container can be used as a control to determine if a peak originated from the container, and a new batch of containers should be checked for the presence of such plasticisers. Interference from phthalate plasticisers can be avoided by using an alkali flame ionisation detector. However, the presence of a trace amount of a volatile phosphate ester produces a large interfering peak with this detector (see Fig. 2, p. 186). These phosphate esters often come from the cap liners of glass containers, and can be removed by using a back-extraction procedure.

Impurities Present in Drugs

Clinical trials and studies of new drugs are usually undertaken with specially purified materials. However, impurities are likely to be present in drugs produced by large-scale manufacture. There is no

evidence that such impurities produce an altered clinical response, but they can affect an analysis. These impurities may be synthetic intermediates, unchanged starting materials, by-products from the reaction process, or decomposition products. In addition, an analyst may be presented with a drug preparation that has been stored at a patient's home for a period well beyond the permitted shelf-life. Some examples of drugs which may contain impurities are given below.

BARBITURATES

Most of the common barbiturates contain a 5-ethyl substituent and some may contain 5,5-diethylbarbituric acid (barbitone) as an impurity. The presence of this compound at a concentration of only 1 to 2% can produce unexpected results. For example, if amylobarbitone containing 1% of barbitone as an impurity caused coma in an overdose complicated by renal failure, the barbitone would form a higher percentage in the blood. This is because amylobarbitone is removed by rapid metabolism in the liver, but barbitone is eliminated more slowly by renal excretion. In the case of coma with renal function being maintained, barbitone would be a major fraction of the barbiturate excreted in the urine; in some cases the concentration has been so high that it has been regarded as a metabolite.

BENZODIAZEPINES

Oxazepam may be present in some pharmaceutical preparations of chlordiazepoxide. Other benzodiazepines may also contain impurities resulting from large-scale manufacture. The differentiation between impurity and drug metabolite is extremely difficult in these cases.

phenytoin

This anticonvulsant has been measured in blood by converting it to benzophenone by permanganate oxidation and then measuring the concentration of the benzophenone. However, benzophenone is also one of the starting materials in the production of phenytoin and its presence has been demonstrated

in some preparations. It is therefore important to obtain a sample of the drug thought to have caused the intoxication and analyse it for the presence of the suspected impurities.

PRIMIDONE

Primidone can be manufactured via the intermediate compound phenylethylmalondiamide. This substance is also one of the principal metabolites of primidone in man and, during therapy, it may be present in blood at concentrations comparable to those of primidone. Toxicologists can often identify an acute over-dosage of primidone if the metabolite concentration in the blood is either very small or non-existent because significant metabolism has not occurred. If the drug contained an impurity that was also a metabolite, the analytical data could present a confusing picture because it would not be possible to state whether metabolism had occurred or not.

Quality Control in Clinical Analysis

D. Burnett and J. Williams

The evaluation of serum-drug concentrations has resulted in a significant improvement in the clinical management of many diseases. This concept of therapeutic drug monitoring has been particularly applied in the field of anticonvulsant, antibiotic, anti-arrhythmic, and antidepressant drugs. It has been reported that 76 to 88% of previously untreated epileptic outpatients could be successfully controlled with a single drug at the appropriate dosage, provided that serum concentrations were regularly monitored. In view of the apparent effectiveness of such an approach, the importance of the accuracy with which the serum determinations are performed becomes self-evident.

When serum-drug concentrations are used as a guide to the adjustment of dosage, the overall impact of an erroneous determination depends on both the patient's actual serum concentration and the therapeutic or optimum range for the drug. Accuracy of measurement within the therapeutic range is perhaps of greatest significance, but it is also important to be able to distinguish clearly between sub-therapeutic, therapeutic, and toxic concentrations. This is important in situations where increasing the dose is likely to induce toxicity; equally, the ability to distinguish between concentrations in the sub-therapeutic range is desirable when monitoring patients on low doses or for evaluating cases of possible non-compliance or enhanced drug metabolism. Quality control is therefore designed to monitor and improve both the precision and accuracy of serum-drug determinations with a view to improving the quality of individual patient care.

There is a certain degree of ambiguity in the terminology which has been used to describe quality control. Because of this ambiguity, some of the more widely used terms are defined below.

The entire procedure of correct patient identification, which includes the collection of the sample from the patient, its analysis, and the return of the data to the requesting physician, is defined by the term *quality assurance*. The long-term continuing assessment of the degree of imprecision of an assay

for a particular drug, with the objective of minimising intra-laboratory variation, is defined by the term *internal quality control*.

The terms inter-laboratory quality control, laboratory proficiency testing, or external surveillance surveys are commonly given to the evaluation of the inter-laboratory variation that is expected when the same sample is analysed by a number of laboratories. In view of the substantial time delay that exists between the actual laboratory analysis of the sample and the receipt of the inter-laboratory comparison, there is no immediate opportunity for controlling the method under investigation and for this reason the term *external quality assessment* is more appropriate.

INTERNAL QUALITY CONTROL

Patients' Samples

The repeat analysis of patients' samples is a commonly used method of assessing imprecision between assays. One or more samples from a previous batch are reanalysed in the next batch and the imprecision (standard deviation, s), determined by analysing the difference (d) between pairs using the formula

$$s = \sqrt{(\sum d^2 / 2n)}$$

where n = number of pairs of samples. A major problem with this approach, which is cheap and simple to operate, is that only two consecutive analytical batches are ever compared, so that the overall between-batch imprecision will be underestimated. In addition, the standard deviation obtained is only an estimate of average imprecision over a wide range of concentrations and is dependent on the range of samples involved, although samples may be grouped in narrow concentration ranges and an average imprecision obtained for each concentration range. Such schemes cannot be recommended for internal quality control on their own as they are insensitive to changes in imprecision and give no indication of the development of systematic errors.

In clinical chemistry, the mean of concentrations of a particular endogenous substance determined each day, e.g. potassium, is sometimes used to

assess the development of systematic error. This method, which is applicable to some endogenous substances, cannot be used to control the development of systematic error when the population is variable both in terms of the dose given to individual patients and in the relationship between dose and serum concentration.

If an assay is being used in which it is customary to duplicate the measurement on each sample within the assay (e.g. immunoassay techniques), then precision profiles can be prepared from the duplicate measurements. This is done by calculating the random error for each pair of samples as a coefficient of variation, given by the expression

$$\frac{|x_1 - x_2|}{\frac{1}{2}(x_1 + x_2)} \times 100\%$$

where x_1 and x_2 are the duplicate measurements. The coefficients are then plotted against analyte concentrations.

These profiles can be used to control the day-to-day performance of the assay and also to optimise its design in relation to imprecision at medical decision points relating to underdosage or overdosage of patients.

Pooled Serum

An alternative method to the repeat analysis of individual patient samples is the preparation of a pool of patient sera containing suitable concentrations of the analyte. However, a more practical answer involves the addition of drugs to a drug-free serum of either human or animal origin. The advantage of such an approach is that the operator knows the approximate drug concentration, although a criticism is that such a preparation does not contain drug metabolites which would be present in the clinical situation and which might interfere with the assay. However, the specificity of an assay should have been thoroughly investigated in the developmental stage and it is doubtful whether repeated analysis of a control sample containing an interfering compound would indicate that such interference was occurring unless a target value was available. The major advantage of using a pool system is that the information obtained is cumulative so that indications of change in performance can be obtained relatively quickly even when the number of control specimens per batch is small.

PREPARATION AND USE OF SERUM POOLS

To prepare a quality control pool it is necessary to

have a drug-free vehicle and high purity drugs or metabolites. In theory, any desired vehicle can be used, but the literature on this subject deals almost entirely with serum or plasma. Serum pools which contain known concentrations of added drug substance are known as spiked pools. The following comments on the preparation of pooled serum quality control material are also relevant to the preparation of calibration material.

The drug-free material must first be analysed by the relevant analytical technique for which the quality control material is being prepared to ensure that there is no interference from endogenous compounds or contaminants introduced during collection and pooling. For example, serum stored in some plastic containers may become contaminated with a plasticiser which interferes with the assay of phenytoin by gas chromatography.

The weighing operations should be carefully planned to give the desired concentration and, since the drugs are added to the serum as a solution, the solubilities of each drug in ethanol/water mixtures should be investigated. Aqueous solutions are preferable, but it is often necessary to use ethanolic solutions and the solution should then be diluted with water to give a 30% v/v solution of ethanol before addition to serum in order to prevent precipitation of proteins. The material must be stable for a reasonable length of time and this requirement applies both to the serum and to the drugs or metabolites being measured. Microbial content of the serum can be removed by sterile filtration through membrane filters, and sodium azide can be added provided this does not interfere with the assay. Storage at 4° is desirable because drug-protein binding does not change as it does during freezing or lyophilisation. There is little information in the literature as to the stability of drugs and metabolites under these conditions. Storage at — 20° should be suitable for most quality control materials, but some serum components precipitate irreversibly on freezing and thawing. To minimise precipitation due to repeated freezing and thawing, the material should be divided into aliquots before freezing. Lyophilisation has similar disadvantages to freezing, but is the most suitable method for material which has to be distributed between laboratories. Experience indicates that lyophilised serum containing anticon-vulsant drugs does not deteriorate when stored for more than 3 years at] — 20°, nor deep-frozen material when stored for one year.

Lyophilised products may be difficult to reconsti-

tute, particularly if stored at room temperature, and storage at 4° is recommended. Thawed or reconstituted lyophilised serum is stable for one to two weeks at 4°.

Quality control materials using serum or urine are commercially available for many drugs which are assayed routinely for therapeutic or toxicological purposes. Such preparations are generally lyophilised and their stability is guaranteed by the manufacturer. The concentration values assigned by the manufacturer should be verified in the user's laboratory before they are used for the construction of control charts.

Ideally, controls should be assayed in duplicate at three concentrations corresponding to below, within, and above the therapeutic range. (Suggested values for some drugs are given in Table 1.)

The advantage of multilevel control is that, if systematic error develops, information may be obtained as to whether the error is proportional to concentration or constant over the assay range. It is also useful to have estimates of imprecision at different concentrations, particularly for methods with non-linear concentration-response relationships.

Table 1. Suggested values for preparing spiked pools

<i>Compound</i>	<i>Low pool</i>	<i>Mid pool</i>	<i>High pool</i>
Amitriptyline	*430 (120)	*650 (180)	*1300 (360)
Carbamazepine	8 (2)	24 (6)	48 (12)
Clonazepam	*90 (25)	*180 (50)	*270 (75)
Desipramine	*560 (150)	*750 (200)	*1500 (400)
Ethosuximide	140 (20)	420 (60)	840 (120)
Imipramine	*550 (155)	*750 (210)	*1500 (420)
Nortriptyline	*190 (50)	*380 (100)	*1520 (400)
Phenobarbitone	20 (5)	60 (15)	180 (45)
Phenytoin	20 (5)	60 (15)	180 (45)
Primidone	15 (3)	45 (9)	90 (18)
Theophylline	55 (10)	82 (15)	165 (30)
Valproic acid	140 (20)	420 (60)	840 (120)

Values are in $\mu\text{mol/litre}$ (approximate $\mu\text{g/ml}$ equivalent) or, when marked with an asterisk, in nmol/litre (approximate ng/ml equivalent)

Unfortunately, quality control of analytical procedures cannot be achieved without increasing the workload, and with batches of less than fifty samples the inclusion of six control samples might be considered excessive. The choice of scheme for smaller batches will depend to a certain extent on the analytical method used. For methods with nonlinear concentration-response curves, the inclusion of at least three concentrations is necessary, whereas for methods with linear concentration-response relationships, cutting down to two or even one

concentration might be considered. If single-point calibration is used (for methods with linear calibration curves) it would be wise to run high and low concentrations alternately because a change in the difference between high and low values may be a useful indicator of loss of linearity of the concentration-response relationship.

If only one or two pools are used, it would be sensible to choose concentrations related to medical decision points, i.e. the low and high ends of the appropriate therapeutic range. Whatever the number of pools used, at least one should be analysed in duplicate in each run, as this permits assessment of within- and between-batch imprecision. The control samples should be spread evenly throughout the batch and each should be preceded by a patient sample and not placed in a protected position. Each pool should be large enough to cover at least sixty batches and, preferably, should be a good deal larger as new pools should be overlapped for thirty batches before introduction for quality control purposes. For research projects of short or medium duration the pool(s) should be large enough to last the duration of the project.

Data Collection and Analysis

This section discusses data collection from a multilevel scheme and suggests ways of recording it on a day-to-day basis. In each assay batch, low, mid, and high controls are assayed in duplicate. Fig. 1 shows the form used for data collection using valproic acid as an example with some typical data entered. The results at each level for each drug are designated x_1 and x_2 and the mean of the two results (\bar{x}) along with the difference (range) between them (d) can be readily calculated. The target mean (\bar{x}_T) for the pool can be established during the overlap period with previous quality control pools and may be calculated from the data in the first twenty to thirty batches together with the target standard deviation (s_T).

If the initial calculation is shown to contain a value more than 3 standard deviations from the mean, the value should be rejected and the mean and standard deviation recalculated. The standard deviation obtained may be used as the target standard deviation (s_T) in preparation of Shewhart charts or a desired standard deviation can be used which might be related to medical need or to a previous period of satisfactory performance. For a practical guide to statistical techniques used in quality control of analytical methods and the preparation of cusum

Date of assay	Low pool $\bar{x}_T = 22.0$ $s_T = 2.8 (2.0)$				Mid pool $\bar{x}_T = 62.0$ $s_T = 4.8 (3.4)$				High pool $\bar{x}_T = 120.0$ $s_T = 7.9 (5.6)$			
	x_1 x_2	\bar{x}	d	sI	x_1 x_2	\bar{x}	d	sI	x_1 x_2	\bar{x}	d	sI
2.4.81	21.1 23.3	22.2	2.2	0.10	63.4 62.9	63.2	0.5	0.35	116.7 118.9	117.8	2.2	-0.39

\bar{x}_T = target mean

s_T = target standard deviation

(value in brackets = $s_T/\sqrt{2}$)

x_1 and x_2 = duplicate assay results ($\mu\text{g/ml}$)

\bar{x} = mean of x_1 and x_2

d = difference between x_1 and x_2

sI = standard deviation interval = $\frac{\bar{x} - \bar{x}_T}{s_T/\sqrt{2}}$

(cumulative sum) and Shewhart mean and range charts, the reader is referred to the booklet *Quality Control in Clinical Chemistry* (1984).

An example of Shewhart mean and range charts for the three-level pools is given in Fig. 2 for data similar to that shown in Fig. 1. The mean (\bar{x}) of the duplicates x_1 and x_2 are plotted on the Shewhart mean chart for each occasion. When plotting the mean of the duplicates the tolerance limits are calculated from the standard error of the mean (SEM), i.e. standard deviation divided by $\sqrt{2}$ when $n=2$. The range chart is less commonly described but is a plot of the differences between replicates (in our case duplicates). It is useful in monitoring the within-batch imprecision of a method, because increasing imprecision may be a first indication of problems in an analytical system. To establish control limits, the range of replicates (d) is measured on 20 to 30 occasions and the mean range calculated. The multiplication factors for control limits for duplicates are 2.45 for the 95% limit and 3.22 for the 99% limit; figures for higher replication are given in *Quality Control in Clinical Chemistry*. A cusum chart for the data in the *high pool* (Fig. 1) is shown in Fig. 3; in this chart, the difference between the target mean and subsequent results is plotted. Small, but definite, changes in slope can imply small trends in the mean value and can act as a useful early

warning system. However, it is not easy with cusum charts to set 'action limits'; they can become unmanageable if the initial mean selected is in error, and when the slope is in excess of 60° it is difficult to see changes in bias. Fig. 3 shows the whole data plotted and the data excluding the value recorded on 7.4.81. Comparison of the two plots shows the major and permanent effect of one aberrant observation on a cusum chart, particularly as reference to Fig. 2 shows that except for the batch on the 7.4.81 the assay was in control throughout the period under consideration.

It is clear that the manual preparation and continual updating of the charts shown in Fig. 2 for a multilevel, multi-analyte quality control system involves a great deal of work. However, it is possible in a multilevel control system to represent all individual values at different levels on one chart which is a variant of the Shewhart mean plot. The difference of an individual value (e.g. x_i) from the target mean (\bar{x}_T) is divided by the target standard deviation (s_T) and thus the position of the individual value is represented relative to the target mean in standard deviation intervals sI , see Fig. 1. The bias of each value, irrespective of its analyte concentration, is therefore represented on the same standard deviation scale. This is very convenient for manual and computer plotting as complex scaling is avoided. Fig. 4 shows an example of this

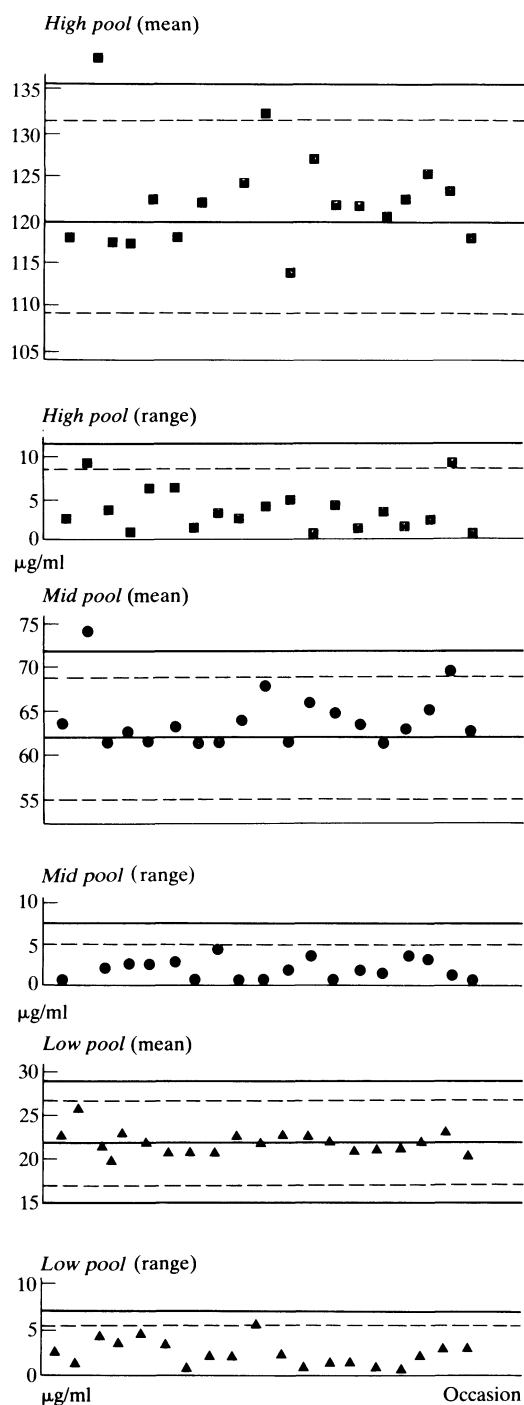

Fig. 2. Shewhart mean and range charts for valproic acid using the data shown in Fig. 1 and similar data from high, mid, and low pools of quality control serum, against occasion of analysis.
 ----- = 95% limits ————— = 99% limits

Fig. 3. The cusum chart for valproic acid using the data shown in Fig. 1 and similar data from the high pool of quality control serum, against occasion of analysis.

on the same data as shown in the Shewhart charts of Fig. 2. Care must be taken in interpretation of these charts as bias may change with analyte concentration and these changes are not easily observed by this representation. However, if each level of control is plotted with a different symbol (Fig. 4), interpretation is made easier. If the bias of the mean of the two results (x_1 and x_2) from the target mean is used (as in Fig. 4) then the standard deviation interval must be calculated using the target standard deviation (s_T) divided by $\sqrt{2}$ as described for conventional Shewhart mean charts.

Fig. 4. The mean of paired results for valproic acid (data from Fig. 1) from high, mid, and low pools of quality control serum, plotted in standard deviation intervals against occasion of analysis.

EXTERNAL QUALITY ASSESSMENT

The first external quality assessment scheme for the determination of anticonvulsant drugs was initiated at St. Bartholomew's Hospital, London in 1972 ('BARTSCONTROL') (A. Richens, 1975). Shortly after this, Pippenger set up a similar scheme in New York whereby three pooled sera containing four anticonvulsant drugs were distributed to laboratories in the USA offering a monitoring service (C. E. Pippenger, 1976). The value of regular participation, whereby the participant in the scheme analyses the quality assessment samples and reports the results to the scheme co-ordinator by the appropriate date, is unquestionable. Marked improvement in analytical standards over a period of many months is a consistent finding with many quality assessment schemes.

Inter-laboratory schemes are also organised in The Netherlands by Dijkhuis at the Central Pharmacy, The Hague, and in Scandinavia by Leskinen and Nyberg at Helsinki. These schemes are not restricted to anticonvulsant drugs, recent schemes having been established for other drugs frequently monitored for therapeutic purposes including digoxin, tricyclic antidepressants, lithium, anti-arrhythmics, theophylline, and the aminoglycoside antibiotics.

The HEATHCONTROL Scheme

This scheme is a development of the original BARTSCONTROL scheme for external laboratory quality assessment. HEATHCONTROL reference sera are prepared by spiking a homogeneous pool of serum with known amounts of the appropriate drugs. The human serum is prepared from Australia antigen-negative drug-free plasma in the following manner. To 1000 ml of pooled, outdated, blood-bank plasma, 5.55 g (50 mmol) of calcium chloride is added and the pH adjusted to 7.4 with 6M sodium hydroxide. The plasma is incubated at 37° for one hour and the serum allowed to drain by placing the formed clot in a large funnel lined with a fine mesh plastic net. The collected serum is then filtered by passing it under vacuum through a combination of two Carlson-Ford filters, the first being a grade 4 general purpose clarifying sheet with a high output and the second a high purity sterilising grade HP/EK. The filtered serum is then spiked with the appropriate drugs. Occasionally, serum with a high lipoprotein content becomes cloudy when a lyophilised specimen is reconstituted with water, thus presenting problems for certain enzyme immunoreactive techniques. To

overcome this the lipoproteins may be precipitated by adding dextran sulphate 300 mg per litre followed by a 30-minute incubation at 25° and centrifugation prior to the filtration step.

For the antiepileptic scheme, for example, 5-ml aliquots of appropriate spiked serum are withdrawn from the pool and lyophilised. The advantage of lyophilisation is that bacterial growth is impaired thus eliminating the need to add bacteriostatic agents, such as sodium azide, which can interfere with certain immunoassay techniques. During a period of a year, samples spiked with the whole range of drug concentrations are distributed. These samples, for monthly analysis, are posted at three-monthly intervals to the participating laboratories along with the appropriate results forms, which have to be returned to the co-ordinator by a stipulated date. These results are evaluated and a computerised printout of the participant's monthly performance is returned within a month of the results having been received. A typical printout is illustrated in Fig. 5. At the end of the year a summary of the laboratory's performance is supplied, enabling the analyst to evaluate his laboratory's performance over the year and to decide whether any technical change should be implemented.

Analysis and Interpretation of Results

The reports provided to participants in external quality assessment schemes should contain a number of important values. As illustrated in Fig. 5, most schemes include data such as the number of participants accepted in the final analysis, the number rejected, i.e. the outliers, the mean and standard deviation of the accepted results, the spiked value together with the individual participant's value and its standard deviation interval (sI) from the consensus mean. In addition, a computerised frequency distribution histogram is generally provided.

PERFORMANCE INDICES

In an attempt to categorise individual laboratory performance, several schemes have introduced a performance index. The calculation of the performance index varies from one scheme to another. The original BARTSCONTROL performance index was based upon ranking the difference between reported and consensus mean values (without sign). These index values ranged from 1 to 10 with 1 indicating a good performance

PERFORMANCE INDEX 4

Fig. 5. A typical computerised printout issued on a monthly basis to participants in an external quality assessment scheme; <<<< represents the position of the reported value of the individual laboratory in relation to the reported values of other laboratories.

and constituting the best 10 per cent of participating laboratories. Those with an index of 10 comprised the worst 10 per cent of the participants. However, it is quite possible for a laboratory with a performance index of 10 to be producing clinically satisfactory results. Conversely, if the overall group performance is poor, results could be clinically unacceptable even when the apparent performance index is good. To overcome this limitation, HEATHCONTROL has since re-evaluated the basis for the calculation of its performance index. The index is now calculated by dividing the 3 standard deviation limits either side of the consensus mean, after the elimination of outliers, into 10 zones each of 0.3 standard deviation units in magnitude. Any participant whose reported result falls within ± 0.3 standard deviation units of the consensus mean is awarded a performance index of 1. A participant whose reported result falls within ± 2.8 to 3.0 standard deviation units of the consensus

mean is awarded an index of 10. The categorisation, while still not independent of the performance of the group as a whole, does rank laboratories relative to the overall performance of all participants. An alternative method for performance index (PI) evaluation has been reported (C. E. Pippenger, 1978) using the formula

$$PI = \frac{\sum_{i=1}^n |R_i - S_i|}{\sum_{i=1}^n S_i}$$

where R_i represents the reported value for an individual specimen, S_i represents the spiked value for that specimen, and n represents the number of specimens used for the calculation of the index. Based upon experience with performance index patterns, it was stated that a PI of less than 10 was exceptionally good, 10 to 20 satisfactory, and above

20 unacceptable. This interpretation is independent of group performance and, assuming that no systematic error is present, is equivalent to requiring intra-laboratory coefficients of variation of less than 5 per cent for excellent and 5 to 10 per cent for satisfactory performance.

I. E. Dijkhuis (1979) ranked results on the basis of percentage difference from the spiked value into super, excellent, good, moderate, and poor categories. The ratio of deviation within these categories was 1:2:4:8:>8 and the combined number of results in the super, excellent and good categories was fixed at approximately 70 per cent. This categorisation was therefore dependent on the performance of the group as a whole and consequently subject to the same criticism as the original BARTSCONTROL index.

None of the methods described for the evaluation of the performance index indicate the direction (+ or -) in which the participant's reported value is different from the mean or spiked value. If this direction were stated and a participant's reported differences were consistently unidirectional, then the recognition of a systematic error would be facilitated.

Further Analysis of Results

If participants in an external quality assessment scheme simply receive the results and check the performance index or some other measure to see if it is satisfactory, a great deal of valuable information is lost. Data from these schemes offer an opportunity to study a laboratory's assay and to assist in the education of laboratory personnel. Simple graphical approaches can be used that do not require complicated calculations. If a laboratory has a computer, more elaborate calculations can be carried out. Basically, the participating laboratory has analysed a sample for a particular analyte and has then to compare the value found with the 'true' value. Possible estimates of the 'true' value include the overall mean for all participants, the method mean, the mean value obtained by designated reference laboratories, or a stated spiked value. Some schemes provide all these values, but the majority provide an overall mean, which will be used in the following discussion. The overall mean has limitations if the technique for elimination of outliers is unsatisfactory or if a particular method, which causes a marked bias at certain concentrations in the overall mean, is used by a significant number of laboratories.

For a day-to-day check on returned results, it is

useful to calculate the difference of the value obtained by the participating laboratory (x) from the overall mean value (\bar{x}). This is the bias ($x - \bar{x}$); it can either be plotted as such against the date of the sample or divided by the standard deviation of results obtained by all participants (s) to give the standard deviation interval (sI) and then plotted against the sample date.

$$sI = \frac{x - \bar{x}}{s}$$

Fig. 6 is a computer plot of standard deviation interval for phenytoin over two years in one particular laboratory. The method of using bias relative to some measure of imprecision, which was first introduced in discussing internal quality control, is particularly useful if data are to be plotted by computer. It is also useful for manual analysis as a single chart can be prepared with lines at 0 ± 2 and $\pm 3 sI$ which can be copied and used for all analytes.

Fig. 6. Standard deviation interval plot for phenytoin. Dotted lines are at 0 and ± 2 standard deviation intervals; '+' marks results outside ± 2.8 standard deviation intervals.

The standard deviation interval approach enables a laboratory to see where its own performance lies in relation to other participants. If a laboratory's performance is equivalent to that of the group (intra-laboratory s = inter-laboratory s) then one would expect a normal distribution about the zero line with nineteen out of twenty points inside ± 2 sI. The limitation of this approach is that it does not analyse bias at different concentrations. If the value obtained by a laboratory is plotted against the overall mean value, this gives a good visual check for linearity of relationship and also an initial indication of the existence of systematic error. Fig. 7 shows data for phenytoin taken from Fig. 6 in which the two years 1979 and 1980 are plotted with different symbols. Fig. 8 shows the same data presented as the bias ($x - \bar{x}$) plotted against the mean (\bar{x}). The scale of the y axis can be expanded to show clearly the change in bias with concentration. Fig. 8 confirms that the phenytoin results were biased high relative to the overall mean during 1979, but it is not possible to say whether the difference was constant or additive. There are a number of explanations for this situation; it would occur if, for example, there was a substance interfering with phenytoin in the samples provided in the assessment scheme which did not occur in the material used for calibration of the assay. It is important to realise that, under these circumstances, the assessment scheme could be

Fig. 7. The value from a participating laboratory (x) plotted against the overall mean value (\bar{x}) of data given in Fig. 6.

indicating that the laboratory was not performing correctly, when in fact the scheme samples were not fully commutable with the routine patient samples. Thus a change may not be called for in the laboratory method, but rather in the samples provided in the assessment scheme. The source of standard for phenytoin was changed at the beginning of 1980 and during that period the performance of the individual laboratory conformed more closely to the overall performance.

Linear regression analysis of the overall mean value against a laboratory's results would be expected to give further information as it provides estimates of slope, intercept, and the standard error of the estimate of bias. These may be used to determine sources of systematic error, proportional (slope), additive (intercept), and random error. However, experience indicates that linear regression analysis is unsuitable for the treatment of such data because the concentration range is limited, the standard error is dependent on the number of laboratories, and analytical precision is not generally constant over the concentration range investigated.

Choice of Method

It would be desirable if scheme co-ordinators could provide newcomers to their particular field with some guidance as to the choice of analytical method, although this has not generally been done. The ability of such schemes to evaluate objectively the suitability of a particular method for a particular drug is unquestionable. Based upon such an evaluation, it has been confirmed that spectrophotometric methods for phenobarbitone, phenytoin,

Fig. 8. Bias ($x - \bar{x}$) plotted against the overall mean value (\bar{x}) of data given in Fig. 6.

and carbamazepine are totally unsatisfactory. These conclusions were based on the number of outliers obtained and on the large coefficient of variation that persisted even after these outliers were excluded. If any meaningful recommendations are to be made about the choice of method, then a detailed description of the methods used by each participating laboratory must be examined. At present, method suitability can only be evaluated by grouping laboratories using a particular class of method, e.g. GC, HPLC, etc., and comparing the performance between these groups statistically. Each month, HEATHCONTROL, for example, produces a method analysis for each drug. In time, such method analysis will enable co-ordinators to advise on the suitability of a particular technique although the advice given is rather tentative in view of the extensive variability that exists within any one class of method.

Only when these variables are sub-classified and the results re-evaluated can a truly objective suggestion be made as to method suitability.

Colour Tests

H. M. Stevens

Many substances give distinct colours when brought into contact with various chemical reagents. In some cases, the colour produced with a particular reagent may be specific for the compound under investigation but, more often, the colour reaction is not confined to a single compound but is produced by a number of the compounds in a given class and sometimes by substances not in that class.

The colour tests specified in the monographs are described below. In a number of the tests, the colour responses of drugs are correlated with particular aspects of the drug structures. However, it is not possible to explain the phenomena fully because anomalous responses often occur for no apparent reason. Some anomalous responses are noted in the following tests but these are not necessarily the only ones which may be found. The colour tests included here have been carefully chosen to give a range of tests for particular functional groups (e.g. Folin-Ciocalteu Reagent for phenols), those for groups of drugs (e.g. Forrest Reagent for phenothiazines), and those which have a wide applicability and give useful and diagnostic colours (e.g. Marquis Test).

INTERPRETATION OF COLOUR TESTS

A wide range of colours is produced by reagents in these colour tests and it is not possible to describe the colours with any degree of certainty since any description is open to the vagaries of subjective assessment. Moreover, the colour obtained in any particular test may vary to a greater or lesser extent dependent upon the conditions of the test, the amount of substance present, and the presence of extraneous material in the test sample.

A system has been adopted, therefore, which uses ten basic colours, i.e. the spectral colours red, orange, yellow, green, blue, violet, together with pink, brown, grey, and black. Variations in hue are indicated by combining two colours, e.g. red-brown, the second named colour being considered to be the dominant colour and this is the main colour used in the lists which follow. Hence, red-brown is listed under brown, whereas brown-red is listed under red. When attempting to interpret the result of a test,

the lists of colours and drug substances should be consulted and, because of the subjective nature of the assessment of colour, it will often be necessary to search the lists given under two main colours, e.g. for red-brown, the lists under both red and brown should be consulted. An arrow between two colours, e.g. red \rightarrow brown, indicates that the colour changes during the course of the test. In the monographs, the notation brown/red is used where there are two parts to a test producing two colours. Occasionally, a test solution may display one colour by reflected light and a different colour by transmitted light. Where this occurs, the solution is referred to as being dichroic.

A final decision on the result of a test should be made by comparing the unknown with a reference substance tested under the same conditions.

The colours recorded are usually those obtained with the free acid or base. In the case of a salt, the colour may be modified by the nature of the other radical present. Basic salts of weak acids may give different colours because of the pH change. Hydro-chlorides usually give a red colour in Mandolin's Test and a blue colour with Koppányi-Zwicker reagent (before addition of pyrrolidine). In the case of a compound extracted from biological material no difficulty will arise, as it will be extracted as the base, but care must be taken in applying colour tests directly to pharmaceutical preparations. These may, of course, be converted to the free base. Bromides and iodides can be converted to the nitrate, which gives the same colour as the base, by the following method. To 0.5 ml of a 1% solution of the salt in *dilute acetic acid*, add 1 drop of an 8% solution of silver nitrate followed by 1 drop of a 2% solution of sodium chloride to remove excess silver. Centrifuge in order to separate the precipitated silver halide and use the supernatant liquid, either as a solution or evaporated to dryness where necessary, for the colour tests.

PRACTICAL POINTS

The tests are designed to work on about 1 mg of the solid drug form unless stated otherwise.

When a solution is not stated to be made in a particular solvent it should be made in water. Where an instruction, time, temperature, etc. appears in brackets after the drug name, e.g. (add water), (15 s), or (slowly at 100°), this indicates a change in the test procedure for that particular drug. It is often useful to run a blank test at the same time as the sample test, so that the colours produced by the sample and by the reagent blank may be compared. When more than one drug is present, or the drug itself is coloured, the colour obtained in the test may be a combination of colours. Although the tests are designed as colour tests for use in test-tubes or on white tiles, in many instances they may be used as TLC locating agents, either sprayed or poured on to the plate.

Certain of the tests described here may be carried out by the micro technique (E. G. C. Clarke and M. Williams, *J. Pharm. Pharmac.*, 1955, 7, 255-262). This applies particularly to Mandelin's Test, Marquis Test, and the Sulphuric Acid test. Information on the direct application of colour tests to urine, blood, and stomach contents can be found under Hospital Toxicology and Drug Abuse Screening (p. 4).

Where an extraction procedure has been carried out with the production of acidic and basic fractions (see p. 11), the tests below may be applied to the evaporated extracts.

COLOUR TEST METHODS

Amalic Acid Test

METHOD. Add to the sample a few drops of 10M hydrochloric acid followed by a few crystals of potassium chlorate, and evaporate the mixture to dryness. Observe the colour of the residue and then add 2 or 3 drops of 2M ammonium hydroxide and again observe the colour.

INDICATIONS. A RED, PINK, ORANGE, or YELLOW residue, changing to PINK, RED, or VIOLET after addition of ammonium hydroxide, indicates the presence of a xanthine.

RED (→ violet)	Bufylline
PINK (→ violet)	Oxpentifylline
ORANGE (→ violet)	Acepiifylline, bamifylline, caffeine, xanthinol nicotinate
Pink-orange (→ violet)	Fenethylline, pentifylline
YELLOW (→ pink)	Etamiphylline
YELLOW (→ violet)	Diprophylline, proxiphylline, theobromine, theophylline

Ammoniacal Silver Nitrate

REAGENT. To 20 ml of 0.1M silver nitrate add sufficient *strong ammonia solution* to dissolve the initial precipitate.

METHOD. Dissolve the sample in a minimum amount of water, with addition of ethanol if necessary, add an equal volume of the reagent, note any colour which develops, then heat the mixture in a water-bath at 100° for 30 seconds.

INDICATIONS. RED, YELLOW, BROWN, or BLACK colours (especially at room temperature) indicate potent reducing power. This occurs when adjacent carbon atoms in a ring each bear an hydroxyl group. There is no response when the hydroxyl groups are *meta* to each other, but there is some restoration of reducing power when they are *para* to each other. Some colour production is also obtained with ethynyl bonds but not with ethylenic bonds.

Colour at room temperature	Compound	Colour at 100°
RED	Isoetharine	Brown-orange
	Hexoprenaline (→ brown → black)	—
	Isoprenaline (→ red-brown)	Brown
	Rimiterol	Brown
YELLOW	Ethinamate	Brown
	Levodopa (→ brown)	Black
Grey-yellow	Hydroquinone	Brown

Colour at room temperature	Compound	Colour at 100°
BROWN		
Red-brown	Adrenaline	Red-brown
	Methyldopa	Black
Orange-brown	Dopamine	Black
	Methyldopate	Orange-brown
GREY		
Red-grey	Protokylol	Brown
BLACK		
	Ascorbic acid	—
	Benserazide	—
	Dobutamine	—
	Dodecyl gallate	—
	Noradrenaline	—

Ethchlorvynol and ethinyloestradiol both give a white precipitate which turns yellow on heating. Carbidopa gives a silver mirror on heating.

Antimony Pentachloride

REAGENT. Dry some antimony trichloride over phosphorus pentoxide, melt the dried material (m.p. 73°), and pass dry chlorine gas into the melt until a yellow fuming liquid is obtained. Add this liquid to about 10 times its volume of chloroform, filter the solution into a dark glass-stoppered bottle, and store in a desiccator.

METHOD. Place 1 drop of an ethanolic solution of the sample on a filter paper, add 1 drop of the reagent, and dry in a current of warm air. Alternatively, the test may be carried out by adding 1 drop of the reagent to the sample on a white tile.

INDICATIONS. Various colours are obtained with the cardiac glycosides, their aglycones, and certain oestrogens and corticosteroids.

No colour is obtained with beclomethasone, cortisone, fluocinolone, flurandrenolone,

RED	Dienoestrol, stilboestrol
ORANGE	Cholesterol (→ brown), deoxycortone, dydrogesterone, fludrocortisone, hydrocortisone, hydroxyprogesterone, strophanthin-K (→ red)
YELLOW	Alphadolone
(→ brown)	Androsterone, digitoxigenin, digoxigenin
(→ brown → black-violet)	Digitoxin, digoxin, lanatoside C, ouabain (very weak)
Green-yellow	Fluocortolone
GREEN	Betamethasone (→ brown), dexamethasone, mestranol, pancuronium
BROWN	Carbenoxolone, dimethisterone, ethinyl-oestradiol (→ black), fluoxymesterone, nor-ethandrolone, norethisterone, oestradiol, oestriol, oestrone, oxymetholone, rotenone
Orange-brown	Enoxolone (→ violet)
Green-brown	Norethynodrel

prednisolone, prednisone, progesterone, testosterone, or triam-cinolone.

Aromaticity

METHOD 1. Place a portion of the sample in each of two ignition tubes and to one tube add some solid sodium hydroxide. Heat both tubes carefully, allow water vapour to escape, insert into the vapours in each tube an open capillary tube containing *Marquis reagent*, and observe the colour of the reagent.

INDICATIONS. RED or ORANGE colours indicate that the sample is aromatic in nature. The colours are probably due to the liberation of traces of aromatic hydrocarbons, phenols, etc.

Colours obtained after heating with sodium hydroxide generally indicate the presence of aromatic acids. Colours obtained after heating without sodium hydroxide generally indicate the presence of phenols, phenolic acids, and aldehydes containing more than one hydroxyl group. A negative result does not necessarily imply that the substance is non-aromatic.

METHOD 2. Add 2 or 3 drops of *nitric acid* to the sample, heat in a water-bath at 100° for 1 minute, cool the mixture, dilute 3 to 4 times with water, and make the solution alkaline by the addition of a 40% solution of sodium hydroxide.

INDICATIONS. A change from COLOURLESS or YELLOW in acid solution to darker colours, e.g. ORANGE or RED-ORANGE, after the addition of sodium hydroxide indicates the presence of a benzene ring in the molecule, probably due to the production of a nitrophenol or other nitro compound. Certain compounds (e.g. diazepam, methaqualone) give a negative result. ORANGE colours are given by certain non-aromatic corticosteroids (e.g. cortisone), by substances containing sulphur, and by compounds which already contain an aromatic nitro group (e.g. nifursol).

Colourless acid solution changing on addition of alkali to:

RED	Clobazam (heat for 3 min with acid)
ORANGE	Butanilicaine, tolazoline
YELLOW	Amprolium, atropine methobromide, hyoscine butylbromide, hyoscine methobromide, ketoprofen, pipazethate, tetrahydrozoline, tetramisole, trimetaphan
VIOLET	Atropine methonitrate (transient), hyoscine methonitrate (transient)
BROWN	Isopropamide

Yellow acid solution changing on addition of alkali to:

RED	Amethocaine, aminacrine, benzonatate, trimethoprim
Orange-red	Dextromethorphan, haloperidol
ORANGE	Amicarbalide, chromonar, dyclonine, glibenclamide, levallorphan, metocurine, padimate, propanidid, quinuronium, salinazid
BROWN	Dibromopropamide, dichlorophen, tubocurarine

Dequalinium gives a red solution in acid, changing to brown-violet in alkali.

Note. Certain substances give distinct colours with cold *nitric acid* but the colours fade on heating: RED, aminacrine (15 s), clozapine, dropropizine, medazepam, trimethoprim; BROWN, metocurine; PINK-BROWN, diethylthiambutene, changing to green; BLACK, tubocurarine.

Benedict's Reagent

REAGENT. Dissolve 1.73g of copper sulphate in 10 ml of water. Dissolve 17.3 g of trisodium citrate and 10 g of anhydrous sodium carbonate in 80 ml of water, with the aid of heat; pour this solution into the copper sulphate solution and dilute the mixture to 100 ml.

METHOD. Add 0.5 ml of the reagent to the sample and heat in a water-bath at 100° for 3 minutes.

INDICATIONS. The formation of RED cuprous oxide occurs with strong reducing agents, e.g. ascorbic acid, dithionites, certain phenolic compounds containing two hydroxyl groups *para* to one another, and compounds containing at least four hydroxyl groups on a non-aromatic ring (e.g. glucose, tetracyclines).

A weak response (ORANGE-BROWN or BROWN colours) is given by streptomycin, hydroxylamine, and substituted hydrazines (e.g. phenelzine). No colour is obtained with beclomethasone, cardiac glycosides, and oestriol (two hydroxyl groups) or clindamycin (three hydroxyl groups).

Carbon Disulphide

METHOD. Mix the sample with 1 ml of water and 0.1 ml of a 1% solution of sodium tetraborate, add 0.2 ml of a 10% v/v solution of carbon disulphide in ethanol, and heat in a water-bath at 100° for 3 minutes; cool the solution and add 3 drops of 0.1 M silver nitrate.

INDICATIONS. A BROWN colour indicates the presence of a dithiocarbamate, suggesting that the original

substance was an aliphatic or heterocyclic primary or secondary amine. The original sample should be tested to ensure that it does not give a brown colour with silver nitrate alone.

Chromotropic Acid

REAGENT. Dissolve 20 mg of chromotropic acid in 10 ml of *sulphuric acid*.

METHOD. Add a small amount of sample, either solid or in solution, to 1 ml of the reagent. Note any colour which may be produced and then add the solution dropwise to 0.5 ml of water, with cooling. Substances which give a colour with cold *sulphuric acid* must be excluded.

INDICATIONS.

RED (before dilution)	Formaldehyde (paraformaldehyde reacts slowly)
VIOLET (after dilution)	Hydrochlorothiazide, hydroflumethiazide

Coniferyl Alcohol

REAGENT. Warm 0.1 g of coniferyl alcohol until it melts (m.p. 74°), dissolve in 3 ml of ethanol, and dilute to 10 ml with ethanol.

METHOD. Place 1 drop of a solution of the sample on a filter paper, add 1 drop of the reagent, and expose the paper to hydrochloric acid fumes.

INDICATIONS. An ORANGE colour indicates the presence of an aromatic primary amine in which the amino group is attached directly to a benzene ring. An anomalous reaction is obtained with diphenylamine (bright orange).

Copper Sulphate

METHOD 1. Dissolve the sample in a minimum volume of 0.1 M sodium hydroxide and add a 1% solution of copper sulphate, drop by drop, until the colour change is complete.

INDICATIONS. GREEN, BLUE or BROWN colours indicate the presence of a sulphonamide.

GREEN	Phthalylsulphathiazole, succinylsulphathiazole (→ violet), sulfadoxine, sulfamerazine (→ brown), sulfametopyrazine, sulfaquin-oxaline, sulphachlorpyridazine, sulphadimethoxine, sulphadimidine (→ brown), sulphaethidole, sulphamethizole, sulphamethoxazole, sulphapyridine (→ brown-green), sulphasomidine
BLUE	Phthalylsulphacetamide, sulphacetamide, sulphaguanidine, sulphanilamide, sulphaphenazole, sulphaurea, sulphinpyrazone, sulthiame

BROWN	Sulphafurazole
Orange-brown	Sulphasalazine
Green-brown	Sulphamethoxypyridazine, sulphamoxole
Violet-brown	Sulphadiazine, sulphamethoxydiazine, sulphathiazole

METHOD 2. Add 1 or 2 drops of a 1% solution of copper sulphate to the sample on a white tile. **INDICATIONS.** A BLUE colour indicates the presence of an alkali salt of a fatty acid, e.g. sodium cromoglycate (1-2 min), sodium valproate. The colours are not produced by a change of pH as negative results are obtained with sodium bicarbonate.

Cyanogen Bromide

REAGENT. (i) Decolorise *bromine solution* by the addition of solid potassium cyanide and then add more *bromine solution* until the solution is pale yellow, (ii) Prepare a saturated solution of aniline in water. These solutions are stable for 1 week. Mix equal volumes of the two solutions immediately prior to the test.

METHOD. Add 1 drop of the mixed reagent to the sample on a white tile.

INDICATIONS. RED, ORANGE, or YELLOW colours indicate the presence of a mono-substituted pyridine ring. Increasing chain-length of the substituent group weakens the response; a delayed response is obtained when the pyridine ring is substituted by nitrogen adjacent to the ring nitrogen; a weak response is obtained where there is a >C=O substituent adjacent to the ring nitrogen. There is no response to the test if the pyridine ring is bound to another ring, nor if it is substituted in more than one position, nor if the nitrogen in the ring is substituted.

Anomalous results are obtained with azatadine (PINK), bisacodyl (no response), and tropicamide (VIOLET-PINK).

RED	Zimeldine (30s)
PINK	Azatadine
Orange-pink	Carbinoxamine, dimethindene, doxylamine, iproniazid, phenyramidol, triprolidine (1-2 min)
Violet-pink	Tropicamide
ORANGE	Azaperone, brompheniramine, chlorpheniramine, isoniazid, metyrapone, nicametate, nicotinamide, nicotine, nicotinic acid, nifenzazone, nikethamide, pheniramine, xanthinol nicotinate
Red-orange	Benzyl nicotinate

YELLOW	Halopyramine, mepyramine, tripeleamine
---------------	--

Diazotisation

METHOD. Dissolve the sample in 2M hydrochloric acid, and to 1 drop on a white tile add 1 drop of a 1% solution of sodium nitrite, and 1 drop of a 4% solution of 2-naphthol in 2M sodium hydroxide.

INDICATIONS. A bright RED or ORANGE-RED colour indicates the presence of a primary aromatic amine. Diphenylamine does not give a reaction; amino-nitrothiazole (solid) gives a VIOLET colour.

p-Dimethylaminobenzaldehyde

REAGENT. Dissolve 0.5 g of *p*-dimethylaminobenzaldehyde in 50 ml of a mixture containing 60 volumes of ethanol and 40 volumes of *sulphuric acid*. The reagent should be freshly prepared.

METHOD. Add the reagent to the sample in a test-tube, warming if necessary. Observe any colour produced and then carefully dilute with water.

INDICATIONS. Colours are given by a number of substances including ergot alkaloids (VIOLET), cannabinols and certain indoles in which the indole ring is not bonded to another conjugated ring (RED changing to VIOLET on dilution), certain phenols and phenolic amines (RED or ORANGE, usually changing to VIOLET on dilution). Some other types of compound also respond.

RED (changing to VIOLET on dilution)	Cannabinols, phenazone (100°, 5 min), pindolol, tryptamine
RED (no violet on dilution)	Benserazide, cocaine (100°, 3 min), feprazone, harmine, phencyclidine (100°, 3 min)
ORANGE (changing to VIOLET on dilution)	Dobutamine, dopamine, orciprenaline, phenol, terbutaline, tyramine
VIOLET	Dihydroergotamine, ergometrine, ergotamine, ergotoxine, lysergide, methysergide

Diphenylamine Test

REAGENT. A 0.5% solution of diphenylamine in sulphuric acid (60% v/v).

METHOD. Apply the reagent to the sample on a white tile or in a test-tube.

INDICATIONS. A BLUE colour indicates the presence of an oxidising agent such as bromate, chlorate, chromate, dichromate, iodate, lead (IV), manganese (III, IV, VII), nitrate, nitrite, permanganate, or vanadate.

Dragendorff Reagent

REAGENT. Dissolve 1 g of bismuth subnitrate in 3 ml of 10M hydrochloric acid with the aid of heat, dilute to 20ml with water, and dissolve in the mixture 1 g of potassium iodide. If black bismuth tri-iodide separates, add 2M hydrochloric acid and more potassium iodide to dissolve it.

METHOD. Dissolve the sample in 3 drops of 2M hydrochloric acid, add 2 to 3 ml of the reagent, and dilute to 10 ml with water.

INDICATIONS. An ORANGE, RED-ORANGE, or BROWN-ORANGE precipitate suggests the presence of an alkaloidal base (precipitated as the alkaloidal bismuth iodide). Positive for primary, secondary, tertiary, and quaternary amines. This reagent is commonly used as a spray for detecting alkaloids on thin-layer chromatographic plates.

Duquenois Reagent

REAGENT. Dissolve 2g of vanillin and 0.3ml of acetaldehyde in 100 ml of ethanol. The reagent should be stored in the dark.

METHOD. Place the sample, or an evaporated petroleum ether extract of the sample, in a test-tube and add 0.5 ml of the reagent and an equal volume of 10M hydrochloric acid. Warm gently and note any colour which is produced and then shake the mixture with chloroform and note if the colour is extracted.

INDICATIONS. A colour change from GREY to GREEN through BLUE to VIOLET-BLUE suggests the presence of cannabis but distinction from roasted coffee and patchouli oil is required. The colour change is best with fresh drug material. Only with cannabis is the violet colour extracted into the chloroform layer.

	Initial colour	Colour extracted by chloroform
Cannabis	Violet-blue	Violet
Coffee (roasted)	Violet-brown	nil
Patchouli oil	Violet	nil
Tea (leaves)	Green-blue	nil

No colour is obtained with other natural products, e.g. basil, bay leaf, eucalyptus oil, mace, marjoram, nutmeg, rosemary, sage, thyme, or tobacco.

Ferric Chloride

METHOD. Add *ferric chloride solution* to an ethanolic solution of the sample.

INDICATIONS. RED, ORANGE, GREEN, BLUE, VIOLET, or BROWN colours indicate the presence of a phenolic compound, fatty acid, or a phenylpyrazoline.

RED	Acetates, phenazone
Brown-red	Nifenazone
ORANGE	Hexoprenaline, propyphenazone, sodium valproate
GREEN	Adrenaline, betanaphthol, dobutamine, dopamine, ethamivan, ethylnoradrenaline, hexylresorcinol, hydroquinone, hydroxyquinoline, isoetharine, isoprenaline, levodopa, methyldopa, methyldopate, noradrenaline, paraphenylenediamine, phenothiazine, protokylol, rimiterol
Blue-green	Chlorquinaldol
BLUE	Apomorphine, dodecyl gallate, gallic acid, morphine, paracetamol, parachlorophenol, phenol, tannic acid
VIOLET	Aminosalicic acid, diflunisal, dipyrone, hexachlorophane (transient), labetalol
Blue-violet	Amidopyrine, salicylamide (after hydrolysis), salicylic acid
BROWN	Aloin, carbidopa
Yellow-brown	Salinazid
Green-brown	Benserazide
BLACK	
Violet-black	Ethyl gallate (→ blue-black)

Ferrous Sulphate

REAGENT. To 1 volume of a 10% solution of ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$) add 5 volumes of *sulphuric acid* with cooling.

METHOD. Add the sample to 0.5 ml of the reagent.

INDICATIONS. A RED or PINK colour is given only by nitrates and nitrites, e.g. glyceryl trinitrate.

Folin-Ciocalteu Reagent

REAGENT. *Stock Solution.* Dissolve 100 g of sodium tungstate and 25 g of sodium molybdate in 800 ml of water in a 1500-ml flask, add 50 ml of *phosphoric acid* and 100 ml of *hydrochloric acid*, and reflux for 10 hours. Cool, add 150 g of lithium sulphate, 50 ml of water, and 4 to 6 drops of bromine, and allow to stand for 2 hours. Boil for 15 minutes to remove the excess of bromine, cool, filter, and dilute to 1000 ml with water.

This stock solution should be stored at a temperature not exceeding 4° and used within 4 months of its preparation; it has a yellow colour and must not be used if any trace of green colour is present. For use, dilute 1 volume of this stock solution with 2 volumes of water.

METHOD. Add the diluted reagent to the sample and make the mixture alkaline with 2M sodium hydroxide.

INDICATIONS. A BLUE colour indicates the presence of a phenolic compound. The reaction is progres-

sively inhibited with increased halogenation of the phenol nucleus.

Formaldehyde-Sulphuric Acid

REAGENT. To 4 volumes of *sulphuric acid* add 6 volumes of *formaldehyde solution*, using a pipette with the tip below the surface of the acid, with stirring and adequate cooling. When the reagent is warm it will remain clear for about 1 hour. If turbidity develops, it may be dispelled by heating in a water-bath at 100° for about 1 minute.

Note. This reagent is not the same as that used in the Marquis Test.

METHOD. Mix the sample with the reagent and heat at 100° for 1 minute.

INDICATIONS. Benzodiazepines generally give an ORANGE colour with the exception of bromazepam and clonazepam (YELLOW), and flurazepam (PINK). Other indications include phenothiazines, tetracyclines, and thioxanthenes. Tryptamine (BROWN) and zomepirac (RED) also react.

RED	*Chlorprothixene, *clonitroxol, fluopromazine, *flupentixol, fluphenazine, metopimazine, pericyazine, promazine, thiothixene, zomepirac
Brown-red	Limecyclyne, oxytetracycline, tolmetin
PINK	Flurazepam, thiopropazine, trifluoperazine
ORANGE	Clonazepam, clonazepam acid, demeclocycline (→ brown-red), demoxepam, diazepam, flunitrazepam, ketazolam, lorazepam, lormetazepam, medazepam (add water), methixene, nitrazepam, nordazepam, oxazepam, prazepam, temazepam, tetrazepam
Red-orange	Methacycline
YELLOW	Bromazepam, clonazepam, dimethothiazine, doxycycline
Green-yellow	Rolitetrazepam (→ yellow-brown), tetracycline (→ yellow-brown)
GREEN	Thiethylperazine
BLUE	Carphenazine, methotrimeprazine, thioridazine
VIOLET	Mesoridazine, perphenazine
Red-violet	Chlorpromazine, diethazine, ethopropazine, mequitazine, methdilazine, perazine, phenothiazine, prochlorperazine, thiopropazate, trimeprazine
Blue-violet	Acepromazine, acetophenazine, piperacetazine, promethazine, propiomazine
Brown-violet	Thiazinamium
BROWN	Tryptamine
Orange-brown	Chlortetracycline, clomocycline

*Fluoresce ORANGE under ultraviolet light (350 nm)

No response is obtained with chlordiazepoxide, dimethoxanate, or proquamezine.

Forrest Reagent

REAGENT. Mix together equal volumes of a 0.2% solution of potassium dichromate, a 30% v/v solution of *sulphuric acid*, a 20% w/w solution of *perchloric acid*, and a 50% v/v solution of *nitric acid*.

METHOD. Dissolve the sample in a minimum volume of 2M hydrochloric acid and add an equal volume of the reagent.

INDICATIONS. RED, PINK, ORANGE, BLUE, or VIOLET colours are obtained with phenothiazines. A BLUE colour is obtained with certain dibenzazepines. The blue colour is inhibited by the presence of phenothiazines, and an excess of reagent must be added to overcome this.

RED	Acepromazine, carphenazine, chlorpromazine, diethazine, dimethothiazine, mequitazine, mesoridazine, piperacetazine, prochlorperazine, promethazine, propiomazine, thiazinamium, thiopropazate, thiopropazine
Violet-red	Perphenazine
Brown-red	Trimeprazine
PINK	Ethopropazine
ORANGE	Fluopromazine, fluphenazine, phenothiazine, trifluoperazine
Pink-orange	Acetophenazine
Red-orange	Methdilazine
Brown-orange	Perazine, pericyazine
BLUE	Clomipramine, desipramine, imipramine, opipramol, thiethylperazine, thioridazine, trimipramine
VIOLET	Methotrimeprazine, proquamezine (→ red → orange)
BROWN	Metopimazine
Red-brown	Promazine

FPN Reagent

REAGENT. Mix together 5 ml of *ferric chloride solution*, 45 ml of a 20% w/w solution of *perchloric acid*, and 50 ml of a 50% v/v solution of *nitric acid*.

METHOD. Dissolve the sample in a minimum volume of 2M hydrochloric acid and add an equal volume of the reagent.

INDICATIONS. The indications for this reagent are the same as those stated for Forrest Reagent.

RED	Chlorpromazine, dimethothiazine, mesoridazine, methdilazine, prochlorperazine, thiazinamium, thiopropazate
Orange-red	Mequitazine
Violet-red	Perphenazine, proquamezine (→ red → orange)
Brown-red	Trimeprazine
ORANGE	Acetophenazine, diethazine, ethopropazine (→ yellow), fluopromazine, fluphenazine, metopimazine, pericyazine, phenothiazine, promethazine, thioproperazine, trifluoperazine
Red-orange	Carphenazine
Pink-orange	Propiomazine (→ red → fades)
Brown-orange	Acepromazine, perazine, piperacetazine
BLUE	Clomipramine, imipramine, thiethylperazine, thioridazine, trimipramine
VIOLET	Methotrimeprazine
BROWN	
Red-brown	Promazine

Fujiwara Test

REAGENT. Freshly prepared *sodium hydroxide solution*.

METHOD. Mix together 2 ml of the reagent and 1 ml of pyridine, add the sample, and heat in a water-bath at 100° for 2 minutes, with shaking.

INDICATIONS. A RED colour in the pyridine layer indicates the presence of compounds which possess at least two halogen atoms bound to one carbon atom. No colour is given by dicophane; 2,2,2-trichloroethanol gives a yellow colour.

Furfuraldehyde

REAGENT. A 10% solution of furfuraldehyde in ethanol.

METHOD. Dissolve the sample in ethanol, place 1 drop of the solution on a filter paper, add 1 drop of the reagent, and expose the paper to hydrochloric acid fumes for 2 to 3 minutes.

INDICATIONS. A BLACK spot indicates the presence of non-aromatic carbamates. *N*-Substituted carbamates do not react.

Iodine Test

METHOD. Mix the sample with an equal volume of manganese dioxide and heat the mixture carefully to dull redness over a small flame. Repeat the test by heating the sample alone.

INDICATIONS. The appearance of VIOLET vapour indicates the presence of iodine in the molecule. Better results are sometimes obtained when the manganese dioxide is omitted, e.g. amiodarone.

Iodoplatinate Test

REAGENT. Add 2 ml of a 5% solution of platonic chloride and 5 g of potassium iodide to 98 ml of water and shake until dissolved.

METHOD. Dissolve the sample in 2 drops of 2M hydrochloric acid, add 2 to 3 ml of the reagent, and dilute to 10 ml with water.

INDICATIONS. A VIOLET, BLUE-VIOLET, BROWN-VIOLET, or GREY-VIOLET precipitate suggests the presence of an alkaloidal base (precipitated as the alkaloid-iodoplatinate complex). The clearest colours are obtained with tertiary and quaternary amines; primary amines give indistinct colours and amines of small molecular weight do not generally react.

Koppanyi-Zwicker Test

REAGENT. A 1 % solution of cobalt nitrate in ethanol.

METHOD. Dissolve the sample in 1 ml of ethanol, add 1 drop of the reagent followed by 10 µl of pyrrolidine, and agitate the mixture.

INDICATIONS. A VIOLET colour is given by substances containing the following structures. *Imides*, in which $>C=O$ and $>NH$ are adjacent in a ring (e.g. barbiturates, glutethimide, oxyphenisatin, saccharin). *Sulphonamides* and other compounds with free $-SO_2 \cdot NH_2$ on a ring (e.g. clopamide, frusemide, sulphanilamide, thiazides), or with $-SO_2 \cdot NH_2$ in a side-chain (e.g. chlorpropamide), or with $-SO_2 \cdot NH_2$ linking a benzene ring with another ring which is other than a pyrazine, pyridazine, pyridine, or pyrimidine ring (e.g. sulphafurazole, sulphamethoxazole). These latter structures give PINK or RED-VIOLET colours (e.g. sulphadiazine, sulphadimethoxine).

No response is obtained with compounds where there are other substituents on the nitrogen atom. Anomalous responses are obtained with paramethadione and theophylline (VIOLET), and with cycloserine, idoxuridine, methoin, niridazole, riboflavine (no response).

Note. Hydrochlorides give a BLUE colour before the addition of pyrrolidine.

Liebermann's Test

REAGENT. Add 5 g of sodium nitrite to 50 ml of *sulphuric acid* with cooling and swirling to absorb the brown fumes.

METHOD. Add 2 or 3 drops of the reagent to the sample on a white tile. Occasionally it is necessary to carry out the test in a tube and heat in a water-bath at 100°.

Many substances give colours with *sulphuric acid* alone, and the test should be repeated using *sulphuric acid* instead of the reagent in order to ascertain that the colour seen is due to the reagent.

INDICATIONS. 1. ORANGE colours are given by substances containing a mono-substituted benzene ring not joined to $>C=O$, $>N-C(=O)-$, or to a ring containing a $>C=N-O-$ grouping.

2. ORANGE or BROWN colours are given by some substances containing two mono-substituted benzene rings (or some di-substituted compounds where fluorine is the second substituent) which are joined

either to one carbon atom or to adjacent carbon atoms.

3. A wide range of colours is given by compounds containing $-OH$, $O-alkyl$, or $-O-CH_2-O-$ groups attached to a benzene ring or to a ring in a polycyclic structure containing a benzene ring. The benzene ring must not bear $-NO_2$, nor be halogenated, nor contain an $-O-$ substituent *ortho* to the oxy groups. Compounds containing ring sulphur give a similar range of colours.

A YELLOW colour is given by a variety of other compounds.

RED	Ajmaline, alprenolol, aminacrine (100°), antazoline, brucine, chlorprothixene, clopenthixol, flupenthixol, mestranol, oxytetracycline, prajmalium, thiazinamium, thiothixene, tolmetin (100°), trifluoperazine, xylazine
Violet-red	Indapamide
Brown-red	Methylchlorophenoxyacetic acid
PINK	Trichlorophenoxyacetic acid (→ brown)
Brown-pink	Prazosin (100° → red-orange)
ORANGE	Aletamine, alverine, ampicillin, atropine methobromide, atropine methonitrate, baclofen, benactyzine (→ brown), bethanidine (→ brown), broxyquinoline, butanilicaine, chloroquine (100°), clidinium (→ brown), cyclandelate, cyclizine, dazomet, decoquinat (slow), diethylthiambutene (100°), dimeflin, diuron, doxapram, dyclonine (100°), fenclofenac (100° → brown), fenitrothion, fempipramide, glibenclamide (100°, 15 s), hyoscine butylbromide, hyoscine methonitrate, linuron, loxapine (50°–60°), methindizate (→ brown), methylphenidate, metolazone (→ green-brown), monolinuron, nomifensine, phenazone (100°), phenelzine, prophan, salinazid, sulphinpyrazone, tolazoline, trimetaphan, tripeleminamine (→ brown), triprolidine, xipamide, zomepirac (100°)
Red-orange	Acetanilide, amphetamines, aniline, atropine, bamipine, beclamide, benethamine, caramiphen, carbetapentane, chlorcyclizine, cinchophen, cycrimine, diphenylpyraline, doxylamine, dropropizine, ephedrine, famprofazone, fencamfamin, glutethimide, hyoscine, hyoscyamine, isoaminile, isocarboxazid, levamisole, meclozine, mephentermine, methixene, methoin, methyl benzoate, methylphenobarbitone, metomidate, morazone, nialamide, pentapiperide, pethidine, phenacetamide, phenbutrazate, phendimetrazine, phenglutamide, pheniramine, phenmetrazine, phenobarbitone, phensuximide, phenylmethylbarbituric acid, phenytoin, prolintane, tofenacin, tranlycypromine, triamterene, triphenyltetrazolium, warfarin
Brown-orange	Ambutonium, bumetanide, diphenhydramine, fenuron, feprazone (100° → brown), ibuprofen, labetalol, mepivacaine, methadone, nefopam (→ brown), tetrahydrozoline
YELLOW	Amicarbalide (100°), clonidine (100° → orange), dequalinium (100° → orange), diethylpropion, diloxanide, ethoxzolamide, fenfluramine (100°), flavoxate, gliclazide, metoclopramide, nifenazone (100°), piroxicam, propachlor, tropicamide
Brown-yellow	Amiodarone
GREEN	Bialamicol, chlorotrianisene, colchicine, dextromoramide (100°), diamthazole, hydrastine, mequitazine, naphthols, phenol, phenothiazine, thiocarlide
Blue-green	Hydrochlorothiazide, hydroflumethiazide, pindolol
Brown-green	Cyclopenthiiazide
Grey-green	Azapropazone
Black-green	Naproxen
BLUE	Amethocaine (100°), amidopyrine (100°), bendrofluazide, benzonatate (100°), chromonar (100°, 3 min), clomipramine, dipyrone (100°), imipramine, mefenamic acid, mefruside, oxypertine, padimate (100°), procabazine (100°, 15 s), propyphenazone (100°) (red with water), yohimbine
Green-blue	Amiphenazole (100°)
VIOLET	Methocarbamol, mianserin, paracetamol, penthienate methobromide, phenacetin, propiomazine, resorcinol, timolol (100°), trazodone (100°) (transient)
Red-violet	Chloroxuron
Black-violet	Methoxychlor

BROWN	Acepromazine, acetophenazine, adiphenine, azacyclonol, barban, benzilium, benzyl nicotinate, biperiden, clemastine, clomiphene, cyclothiazide, dextropropoxyphene, dichlorprop, dicophane, diperdon, diphen-anil, diphenidol, emeprium, etenzamide, fempiprane, flurbiprofen, haloperidol, mepenzolate, methyl-piperidyl benzilate, mexiletine, nadolol, penfluridol, phenaglycodol, phenylbutazone (100°), phosalone, pimozide, pipazethate (100° → red), pipoxolan, pyrrobutamine, rotenone, sotalol (100°), sulindac, veratrine, zimeldine
Red-brown	Benzthiazide, bisacodyl, carphenazine, chlorpromazine, diclofenac, dothiepin, ethopropazine, etisazole, fenbufen, fenoprofen, methapyrilene, perphenazine, polythiazide
Pink-brown	Metoprolol
Orange-brown	Benazolin, diphenadione, maprotiline, methiocarb, piperidolate
Green-brown	Methdilazine, norbormide, promazine, thiopropazate
Violet-brown	Bamethan, clofibrate, dichlorophen
Black-brown	Mecoprop
GREY	Isopropamide
BLACK	Acetomenaphthone, aloin, aminophenols, amodiaquine, apomorphine, atenolol, benorylate, benzquinamide, buprenorphine, butorphanol, carbaryl (→ green), carbidopa, cephaeline, chloroxylenol, chlorphenesin, clomocycline, clorgyline, codeine, cotarnine, cresol, cyclazocine, dextromethorphan, diamorphine, dibromo-propamidine, diprenorphine, doxepin, emetine, ethamivan, ethinyloestradiol, etilefrine, frusemide, glycopyr-ronium, guaiphenesin, hexobendine, hydroxyephedrine, hydroxystilbamidine, ibogaine, indomethacin, levallorphan, mebeverine, mescaline, methylchlorophenoxyacetic acid, methylenedioxyamphetamine, mor-antel, morphine, naloxone, 1-naphthylacetic acid, narceine, nicergoline, normetanephine, noscapine, noxiptyline, octaphonium, oestradiol, oestriol, oestrone, oxprenolol, oxyphenisatin, papaverine, pholcodine, pizotifen, practolol, profadol, propanidid, protokylol, pyrantel, rimiterol, ritodrine, rotenone, salbutamol, terbutaline, tetrabenazine, tetracycline, thymol, trimethobenzamide, trimetozine, tubocurarine, verapamil, viloxazine

Mandelin's Test

REAGENT. Dissolve 0.5 g of ammonium vanadate in 1.5 ml of water and dilute to 100 ml with *sulphuric acid*. Filter the solution through glass wool.

METHOD. Add a drop of the reagent to the sample on a white tile.

INDICATIONS. When interpreting the result of this test, account should be taken of the colour given by Sulphuric Acid and by Liebermann's Test. Hydrochlorides give a red colour with this reagent. When the colours differ from those given with Sulphuric

Acid or Liebermann's Test, this indicates an aromatic ring together with a saturated 5-, 6-, or 7-membered ring containing only one nitrogen atom. The heterocyclic ring must not contain a second nitrogen atom, nor an oxygen atom, nor must it be substituted, nor bound by —CO·NH— to the aromatic ring. The aromatic ring must not have —CF₃ as a substituent. Colours are also produced if sulphur is in a ring, provided that the ring does not contain more than one nitrogen atom.

RED	Ajmaline, azacyclonol, chlorprothixene, diperdon (→ green), dofamium (→ brown), flupenthixol, gelsemine (→ green), indapamide, mequitazine, methotrexate, nialamide, pericyazine, prajmalium, prolintane, sodium cromoglycate, thiothixene, xylometazoline
Brown-red	Nadolol
ORANGE	Dropropizine (slow), ethylnoradrenaline, hydrastinine (→ green), lachesine (→ green), levamisole (→ grey-green), methanthelium, methixene, methyl dopa, methyl dopate, methylpiperidyl benzilate (→ brown → green), noradrenaline, orphenadrine, pipenzolate (→ green), poldine methylsulphate (→ green → violet), propantheline, proquamezine (→ violet), solanidine (→ violet → blue), solanine (→ violet → blue), sulindac, thenalidine (→ brown)
Red-orange	Cotarnine (→ brown)
Green-orange	5-Methyltryptamine
Brown-orange	Mexiletine
YELLOW	Azaperone, benztropine, broxaldine, chelidonine (→ green), conessine, depropine, desipramine (→ blue), dihydralazine, diphenhydramine, diphenidol, diphenylpyraline, dropropizine (→ orange), halquinol, hom-idium, lidoflazine, methacycline (→ orange-violet), paraphenylenediamine, penicillamine, protokylol (→ brown), tofenacin, tylosin (→ yellow-brown), veratrine (→ orange → violet-brown), viprynum
Orange-yellow	Hexoprenaline
Green-yellow	Methoxamine

GREEN	Acepromazine (→ red), adiphenine (→ blue), benorylate, bethovenium hydroxynaphthoate, bibenzonium, buclorsamide (blue rim), bunamidine, chlorpromazine (→ violet), clefamide (→ brown), codeine, colchicine, cyclazocine, cyclomethycaine (→ brown), debrisoquine, diaveridine, dibenzepin, diethazine (→ violet with excess reagent), diethylthiambutene (→ green-blue), dimethindene, dimethoxanate (→ brown), dimoxyline, dipipanone (→ blue), dothiepin, doxorubicin, doxycycline (→ yellow), ethopropazine (→ violet), fenpiprane, guanoxan, harman, hydroxyephedrine, isoxsuprine, metanephrene, methadone (→ blue), methdilazine (→ violet), methocarbamol, methoxyamphetamine, methylenedioxyamphetamine (→ blue), α -methyltryptamine (→ orange), metopimazine, monocrotaline, niclosamide, nitroxoline, norharman (→ yellow), normetanephrene, obidoxime (→ blue), oleandomycin, oxymetazoline, pecazine (→ violet), pentazocine, perazine (→ violet), phenazone, phenazopyridine, phenformin, phenindamine, phenoxybenzamine (→ violet), phenyltoloxamine, pindolol, piperacetazine (→ red → violet), pipoxolan (→ brown), prenylamine, proflavine, promazine (→ violet), promethazine (→ violet), propranolol, reserpine, ritodrine, thenium, thenyldiamine, thiocarbide (→ yellow), tranlycypromine (→ violet), trifluomeprazine (→ red-violet)
Yellow-green	Normethadone, opipramol
Blue-green	Benzoctamine, berberine (→ brown), edrophonium, hydroxystilbamidine, ketobemidone, methoxyphenamine, phentolamine, profadol (→ green), viloxazine
Brown-green	Benzydamine, chlorphenesin
Grey-green	Alverine, azapropazone, benzhexol, diamphenethide, diethyltryptamine (→ yellow), dihydrocodeine, guaiphenesin, hordenine, levomethadyl acetate, normorphine, oxyphencyclimine, papaverine, terbutaline
BLUE	Bamethan (→ green), clomipramine, deserpidine (→ green), desferrioxamine (→ violet), doxapram, droperidol (→ green), harmine (→ green), imipramine (add water), maprotiline, mebhrolin, metaminalol, phenaglycodol, phenylramidol, pyridoxine (→ grey-green), salbutamol (blue rim → brown rim), thioridazine (→ violet), trimipramine (add water), triphenyltetrazolium (slow), xipamide, xylazine, yohimbine (→ green)
Green-blue	Chlophedianol, labetalol
VIOLET	Amidephrine, benperidol, bezitramide (→ orange), bisacodyl, captodiamine, cephaloridine, chlorpyrilene (→ orange), clomiphene (→ orange-brown), clomocycline (→ brown), denatonium, dipyridamole, guanoclor (→ orange → brown-yellow), guanoxan, hexobendine, hydromorphone (→ orange), mepacrine (→ yellow), mepyramine, methisazone (→ yellow), mianserin, morantel, naloxone (→ brown), oxyclozanide (→ orange), oxyphenisatin, oxytetracycline (→ red → orange), penthienate, perphenazine, phenylbutazone, pizotifen (→ green), prilocaine, primaquine (→ orange), propiomazine, pyrantel, pyrrobutamine, rolitetracycline (→ red → orange), strychnine, tetracycline (→ red → orange), thiethylperazine, thiopropazate, triacetyloleandomycin (slow), tridihexethyl, trimeprazine, trimetazidine
Red-violet	Antazoline, carphenazine, dimethothiazine, histapyrrodine, thonzylamine
Blue-violet	Alcuronium, hexocyclium, methotrimeprazine
Brown-violet	Alprenolol, bitoscanate, butaperazine, naphazoline
Grey-violet	Methoserpidine, oxprenolol, tricyclamol
Black-violet	Methapyrilene
BROWN	Amitriptyline (→ green), azapetine, bamipine, carbetapentane (slow), clidinium (→ green), cyclopentolate, diphemanil, dipyrone, doxepin, embutramide, fluanisone, fluphenazine, isoetharine, isometheptene, isoprenaline, methindizate, methyl benzoquate, methysergide, metoclopramide, norpiperanone (→ blue), nortriptyline (→ green), phenelzine, phenylephrine, pimozide, piperidolate, prochlorperazine (→ violet), propoxycaine, rescinnamine, salinazid, stanazolol, tetrabenazine, thioproperazine (→ green → violet), tolafate, tolpropamine, tramazoline, tubocurarine
Red-brown	Benzthiazide, clioxanide, cycrimine, decoquinat, diclofenac, ethomoxane, fluopromazine, hydrastine (→ red), trifluoperazine
Pink-brown	Metoprolol
Orange-brown	Rifampicin, spiramycin, thebaine
Yellow-brown	Clemastine, clofazimine, physostigmine, rifamycin SV, trimethoprim, tripelennamine
Green-brown	Etenzamide, harmaline, lysergic acid, mesoridazine, narceine, syrosingopine
Violet-brown	Chlortetracycline (→ yellow), cyproheptadine, demeclocycline, dihydroergotamine, ergotamine, lymecycline (→ yellow), methylergometrine, nicergoline (→ brown), octaphonium, oxethazaine, protriptyline, trimethobenzamide
Grey-brown	Dextropropoxyphene, mephensin carbamate
GREY	Dihydromorphine, diprenorphine, etilefrine (→ green → brown), ibogaine (→ violet), indomethacin, lobeline, lysergide, oxypertine, propranolol, trazodone (→ violet)
Blue-grey	Alphaprodine, diamorphine, morphine
BLACK	Procyclidine

Marquis Test

REAGENT. Mix 1 volume of *formaldehyde solution* with 9 volumes of *sulphuric acid*.

METHOD. Add a drop of the reagent to the sample on a white tile.

INDICATIONS. Various colours representing the whole of the visible spectrum are given by a large number of compounds. Structures which tend to maintain the response to the reagent at the violet

end of the spectrum are, in decreasing order of efficacy: ring sulphur (with or without aromatic ring); ring oxygen (with aromatic ring); extra-ring oxygen or sulphur (with aromatic ring); aromatic compounds which consist entirely of C, H, N. Thus, there is a tendency for the response to Marquis reagent to move gradually towards longer wavelength, i.e. through green to orange and red, as the ratio of C, H, N to the other groups in the molecule rises.

RED	Alprenolol, benzylmorphine (→ violet), buphenine, dimethothiazine, etenzamide, etilefrine, fenclofenac (slow), fenpiprane, fluphenazine, flurbiprofen, hexoprenaline, labetalol (→ brown-red), maprotiline, mephesisin carbamate, mequitazine (slow), mesoridazine (→ violet), methoxyphenamine, metopimazine, mexiletine, nadolol, pentazocine (→ green), pericyazine, phenazopyridine, phenoperidine, phenylephrine, piperacetazine, prenylamine, thebaine (→ orange), thiethylperazine (→ green), thioproperazine, thiothixene, tolpropamine, tranlycypromine (→ brown), vinblastine
Orange-red	Alverine, bethanidine, diphemanil, flupenthixol
Violet-red	Thioridazine (→ blue-green)
Brown-red	Alphaprodine
PINK	Fenopropfen, metoprolol
ORANGE	Adrenaline (→ violet), aletamine, amphetamine (→ brown), anileridine (slow), benactyzine (→ green → blue), benzethonium, benzilium (→ green → blue), benzphetamine, bunamidine (→ red), carbetapentane (slow), carphenazine (→ red-violet), clidinium (→ blue), cyclandelate (slow), cycrimine (→ red), dehydroemetine, dimethyltryptamine, dipyridamole, ethacridine (→ red), ethoheptazine, ethylnoradrenaline (→ brown), famprofazone, fenbufen (→ brown), fencamfamin, fenethylline, fentanyl, harmine, indapamide (→ violet), indomethacin, isothipendyl, ketobemidone, lachesine (→ green → blue), lymecycline, mepenzolate (transient), mephentermine (→ brown), mescaline, metanephine (→ violet-brown), methacycline, methanthelinium, methindizate (→ green), methylamphetamine, methylpiperidyl benzilate (→ green → blue), 5-methyltryptamine (→ brown), α -methyltryptamine (→ brown), <i>N</i> -methyltryptamine, nefopam (→ brown), nomifensine (slow), normetanephine (→ violet-brown), oxeladin, oxytetracycline, pentapiperide, pethidine, phenethylamine, phenformin (→ brown), phentermine, piminodine, pipenzolate (→ green → blue), piperidolate, pizotifen (→ red), poldine methylsulphate (→ green → blue), primaquine, profadol (→ red-brown), prolintane (→ brown), propantheline, prothipendyl, psilocybin, rolitetracycline, spiramycin, tetracycline, trimethoprim, trimethoxyamphetamine, tryptamine, veratrine, xylometazoline
Red-orange	Chlorprothixene
Pink-orange	Diuron
Yellow-orange	Orphenadrine, pipradrol
Brown-orange	Amitriptyline
YELLOW	Acridine (→ red), amiloride, azacyclonol, benzquinamide, benztropine, bromodiphenhydramine, broxalidine, broxyquinoline, caramiphen, chlordiazepoxide, chlorphenoxamine (→ green), chlortetracycline (→ green), chlorthalidone, cinchophen, clefamide, clemastine (green rim), colchicine, conessine (→ orange), cyclizine, demeclocycline (→ green), depropine, diethyltryptamine (→ brown), diphenhydramine, diphenidol, diphenylpyraline, DOM, doxycycline, ethoxzolamide, ethylmorphine (→ violet → black), furaltadone, halquinol, hydrocodone (→ brown → violet), hydromorphone (→ red → violet), hydroxyephedrine, isoetharine (→ orange), lidoflazine, lorazepam, mepacrine, methyl dopa (→ violet), methyl dopate (→ violet), norcodeine (→ violet), orciprenaline, oxycodone (→ brown → violet), oxyphenbutazone, phanquone, phenbutazate (slow), phentolamine, phenylamidol, pindolol (→ brown), pramoxine (→ green), proflavine (→ orange), salbutamol, salinazid, sodium cromoglycate, solanine (→ violet), terbutaline, tetrabenazine, thebacon (→ violet), tofenacin, triamterene, trimetazidine (fades), vancomycin, viprynum embonate, zomepirac (100°, → orange)
Orange-yellow	Stanozolol

GREEN	Berberine, carbaryl, chelidonine, harman, norharman, oleandomycin, propranolol, protriptyline, pseudomorphine, sulindac (slow)
Yellow-green	Acepromazine (→ red), verapamil (→ grey)
Blue-green	Tolnaftate
Brown-green	Harmaline
Grey-green	Cyproheptadine, deserpidine, naphazoline, oxypertine, phenindamine, protokylol, rescinnamine, reserpine (→ brown)
BLUE	Clofibrate, embutramide, nicergoline (→ grey)
Grey-blue	Mebhydrolin, 1-naphthylacetic acid
VIOLET	Apomorphine (→ black), azatadine, benorylate, bisacodyl, buprenorphine, butriptyline, captodiame, chloropyrilene, chlorpromazine, clofazimine, codeine, diamorphine, diethylthiambutene, dihydrocodeine, dimethindene (→ blue), dimethoxanate, doxorubicin, doxylamine, ethopropazine, ethoxazene, guaiphenesin, guanoxan, hexocyclium methylsulphate, mepyramine, 6-monoacetylmorphine, morphine, nalorphine, normorphine, oxprenolol, oxyphenisatin, pecazine, penthienate, perazine, perphenazine, phenoxybenzamine, phenyltoloxamine, pholcodine, pimozide, pipoxolan (→ grey), prochlorperazine, procyclidine, promazine, promethazine, proquamezine, solanidine, thenium, thiopropazate, tricyclamol, trimeprazine, viloxazine
Red-violet	Acetophenazine, benzocetamine, bphenium hydroxynaphthoate, cephaloridine, chlrophedianol (→ brown), dihydromorphine, ethomoxane, fluopromazine, isoxsuprine, lobeline, methdilazine, propiomazine, tramazoline, trifluomeprazine, trifluoperazine, trimeperidine
Blue-violet	Methocarbamol, methotrimeprazine, morantel, neopine, noscapine (fades), pyrantel
Brown-violet	Butaperazine, dopamine, tridihexethyl
Grey-violet	Benzhexol, diprenorphine, oxymorphone, pyrrobutamine, thenalidine
Black-violet	Dextropropoxyphene (→ green), methapyrilene, thenyldiamine
BROWN	Bibenzonium, carbidopa, cyclazocine (→ green), diclofenac (slow), dimoxyline, dothiepin, doxepin, ergometrine, ergotamine, erythromycin, hordenine (→ green), ibuprofen (100°, → orange), isoprenaline (→ violet), lysergamide, lysergic acid, naloxone (→ violet), naproxen, narceine (→ green), noradrenaline, phenazocine, rimiterol (→ black), serotonin (slow), syrosingopine, tyramine (→ green)
Red-brown	Biperiden, debrisoquine, methyl benzoquate, oxethazaine, phenprobamate, trimetozine, tripeleennamine
Orange-brown	Benethamine (→ brown), clomocycline, nortriptyline
Yellow-brown	Ritodrine, thymoxamine, triacetyloleandomycin, tylosin
Green-brown	Alcuronium, bufotenine, psilocin
Violet-brown	Clomiphene, diethazine, levomethadyl acetate (→ grey-green), methoxamine (→ green)
Grey-brown	Dihydroergotamine, methylergometrine, octaphonium
GREY	Butorphanol, diaveridine (→ violet-brown), ibogaine (→ orange), lysergide, methoserpidine, methysergide, pholedrine (→ green)
Blue-grey	Acetorphine (→ yellow-brown), etorphine (→ yellow-brown)
BLACK	
Blue-black	Methylenedioxymphetamine

McNally's Test

REAGENTS. (i) A 0.5% solution of copper sulphate in 10% acetic acid. (ii) A freshly-prepared 2% solution of sodium nitrite.

METHOD. To the sample in 1 ml of water add 0.2 ml of ethanol or acetone, 3 drops of the copper sulphate solution, and an equal volume of the sodium nitrite solution, shake, and heat in a water-bath at 100° for 3 minutes.

INDICATIONS. A RED colour indicates the presence of free salicylic acid.

Aminosalicylic acid gives a BROWN precipitate; diflunisal gives a VIOLET colour. Certain acids which are produced during the putrefaction of tissues also

give RED colours in this test: *p*-hydroxyphenylacetic acid; *p*-hydroxyphenylpropionic acid; *p*-hydroxyphenyl-lactic acid.

Mercurous Nitrate

REAGENT. To a saturated solution of mercurous nitrate add solid sodium bicarbonate until effervescence ceases and the precipitate formed becomes yellow. The precipitate then changes to a biscuit colour. This reagent should be freshly prepared, shaken immediately before use, and should not be kept for more than 1 hour.

METHOD. Dissolve the sample in the minimum amount of ethanol, add 1 drop of the opaque

reagent, shake, and examine at intervals during 2 minutes. A blank solution containing only ethanol and reagent should be treated similarly at the same time.

INDICATIONS. A dark GREY or BLACK colour indicates (i) a ring imide group, or (ii) sulphonamides with an additional ring.

The speed and intensity of the reaction varies between different compounds. The following ring imides react in decreasing order of intensity, barbiturates, bemegride, phenytoin > benperidol, cycloserine, pimozide > glutethimide, oxyphenis-atin > saccharin, sulphinpyrazone. In the case of sulphonamides, succinylsulphathiazole, sulphamoxole, sulphanilamide, sulphasomidine, and sulphathiazole react with greater intensity than all others. Chlorpropamide and tolbutamide give a moderate response.

Methanolic Potassium Hydroxide

REAGENT. A 20% solution of potassium hydroxide in methanol.

METHOD. Add a few drops of the reagent to a solution of the sample in methanol and heat to develop the colour, if necessary to boiling-point.

INDICATIONS. A change from colourless or from a pale colour to RED, ORANGE, YELLOW, GREEN, or BLUE is given by quinones, diones possessing an aromatic ring, phenols with adjacent hydroxy groups, and by compounds containing nitro groups on a ring. Many of these compounds are coloured already and give pale or colourless solutions in methanol.

RED	Benserazide, isoetharine (→ orange → yellow), metronidazole, nitrofurazone, phenindione
Orange-red	Fenitrothion, quintozone, tecnazene, trifluralin
PINK	Levodopa (→ red-brown)
Orange-pink	Rimiterol
Brown-pink	Dobutamine
ORANGE	Acinitrazole, barban, carbidopa, dinitro-orthocresol (100°), dinobuton, dinoseb, dodecyl gallate, hexoprenaline (→ brown), isoprenaline (→ yellow), nifedipine, nifuratel, nifursol, obidoxime, protokylol (→ yellow)
Pink-orange	Adrenaline (→ brown)
Yellow-orange	Nitrofurantoin
YELLOW	Acebutolol, diphenadione, methyl dopa (→ orange), metolazone, niclosamide, niridazole, nitroxoline, nitroxynil, phanquone (→ brown-violet), sodium cromoglycate
Green-yellow	Phytomenadione (→ violet → brown)

GREEN

BLUE

VIOLET

Apomorphine (→ red), dinitolmide

Dopamine (→ orange → brown), methyl dopate (→ orange), noradrenaline (→ orange)

Dimetridazole (when boiled)

Millon's Reagent

REAGENT. Dissolve 3 ml of mercury in 27 ml of *fuming nitric acid* and add an equal volume of water with stirring.

METHOD. Add 0.5 ml of reagent to the sample and warm the mixture.

INDICATIONS. A RED or ORANGE-RED colour indicates the presence of a phenolic substance. Primary aryl amines also react. Some basic compounds which contain a phenolic group do not react to this test; a combination of this test with the Folin-Ciocalteu Reagent is therefore advised for phenolic compounds.

Naphthol-Sulphuric Acid

Note. This test should be carried out in conjunction with the Sulphuric Acid test (p. 145).

REAGENT. Mix 1 g of 2-naphthol with 40 ml of *sulphuric acid* and heat in a water-bath at 100°, with occasional stirring, until the 2-naphthol is dissolved.

METHOD. Mix the sample with 1 ml of the reagent, heat in a water-bath at 100° for 2 minutes, and note any colour produced. Cool, add 1 ml of water, and note the colour again.

INDICATIONS. A range of colours is obtained with steroidal structures (see below). A positive response to this test combined with a positive response to the Sulphuric Acid test is indicative of the presence of a steroid.

Compounds other than steroids which give colours with this test include chloral hydrate and chloramphenicol (brown-yellow), starch, and tartaric acid (green).

Colour with hot reagent	Steroid	Colour after dilution
RED	Mestranol	Red
Orange-red	Deoxycortone	Blue-black
	Dydrogesterone	—
	Hydroxyprogesterone	Blue, violet (dichroic)
	Norethynodrel	Brown-red
Brown-red	Ethinylestradiol	Pink
ORANGE	Norethisterone	Orange-brown
Orange, green (dichroic)	Norethandrolone	Red-orange

<i>Colour with hot reagent</i>	<i>Steroid</i>	<i>Colour after dilution</i>
YELLOW	Stilboestrol Testosterone	Orange Green, brown (dichroic)
Green-yellow	Fluoxymesterone	Yellow
GREEN	Beclomethasone Fluocinolone	Brown-yellow Yellow
Yellow-green	Dexamethasone	Yellow
Green, yellow (dichroic)	Oestriol	Orange
	Oestrone Triamcinolone	Orange Yellow
Green, brown (dichroic)	Flurandrenolone	Yellow
Blue-green, yellow (dichroic)	Oestradiol	Orange
VIOLET	Fludrocortisone	Brown
BROWN	Oxymetholone Prednisolone Prednisone Progesterone	Pink-orange Brown Orange Yellow
Red-brown	Dimethisterone Enoxolone Fluocortolone	Brown-green Orange Red-brown
Orange-brown	Alphadolone Androsterone Cortisone Dienoestrol	Orange Orange Orange Yellow
Yellow-brown	Carbenoxolone Cholesterol Hydrocortisone	Orange Violet Yellow-brown
Green-brown	Betamethasone	Orange-brown

Nessler's Reagent

REAGENT. To a saturated solution of mercuric chloride add solid potassium iodide until the initial red precipitate just dissolves; then add an equal volume of a freshly-prepared 40% solution of sodium hydroxide.

METHOD. Add the reagent to the sample and heat the mixture to 100° in a water-bath, examining it every minute for 10 minutes. A blank solution should be treated similarly at the same time.

INDICATIONS. A BROWN-ORANGE colour is produced quickly by aliphatic amides and thioamides. The presence of an aromatic ring slows the reaction and the nearer the amide group is to the ring, the more the reaction is inhibited. Substituents in the ring may cause a weak reaction.

An immediate BLACK colour is produced by substances containing *ortho* or *para* hydroxy groups and by substances containing an —NH—NH— or —NH—NH₂ group in an aliphatic side-chain.

Some compounds must be heated to 100° to produce blackening.

ORANGE	Acebutolol (slow), carbidopa (→ black), methotrexate
Brown-orange	Acetylcarbromal (slow), bromvaletone, carbromal, chloramphenicol, dinitolmide, etenzamide (weak), ethionamide, fluoroacetamide, nicotinamide, phenacetamide (slow), pheneturide (slow), prothionamide, pyrazinamide, salicylamide (weak), urea
YELLOW	Dihydrostreptomycin (→ brown), penicillamine
BROWN	Demeclocycline, mebutamate (slow), nadolol, paracetamol (slow)
Yellow-brown	Atenolol (slow)
BLACK (immediate)	Adrenaline, apomorphine, ascorbic acid, benserazide, dihydralazine, dobutamine, dodecyl gallate, dopamine, ethylnoradrenaline, hexoprenaline, hydralazine, iproniazid, isocarboxazid, isoetharine, isoniazid, isoprenaline, levodopa, mebanazine, methylidopa, methylidopate, nialamide, noradrenaline, phenelzine, procabazine, protokylol, rimiterol
BLACK (at 100°)	Cimetidine, gentamicin, labetalol, meprobamate (grey-black), methallibure, salinazid, thiacetazone

Ninhydrin

REAGENT. Dissolve 0.5 g of ninhydrin in 40 ml of acetone.

METHOD. Dissolve the sample in methanol, place 1 drop of the solution on a filter paper, add 1 drop of the reagent, and dry in a current of hot air.

INDICATIONS. A VIOLET colour, appearing rapidly, indicates the presence of an aliphatic primary amine or an amino acid group. The presence of an aromatic ring inhibits the response, the inhibition increasing the nearer the amino group is to the ring, e.g. amphetamine (PINK-ORANGE), procainamide and proxymetacaine (both YELLOW). If the amino group is associated with a saturated ring, a positive but weak PINK-VIOLET colour is obtained (amantadine, rimantadine). Gentamicin gives a VIOLET colour after heating for 4 minutes.

Nitric Acid, Fuming

METHOD. Mix the sample with 3 drops of *fuming nitric acid*, heat at 50° for 30 seconds, and observe any colour produced. Cool the mixture, add 2 drops of it to 2 ml of *sulphuric acid*, and observe the colour. To the remainder of the cooled mixture, add 2 ml

of water followed by 2M sodium hydroxide, dropwise, until a pH of 8 is obtained (use an indicator paper).

INDICATIONS. Chlorinated phenols give a series of colours in the three parts of this test.

ORANGE-RED/ORANGE/ORANGE-BROWN	Hexachlorophane
RED/RED/BROWN-VIOLET	Pentachlorophenol

Nitric-Sulphuric Acid

REAGENT. Mix 1 ml of *nitric acid* with 30 ml of *sulphuric acid*.

METHOD. Dissolve the sample in 1 ml of ethanol, add a pellet of potassium hydroxide, and evaporate to dryness at 100° in a water-bath. To the residue add 0.5 ml of water and 1 ml of carbon tetrachloride, shake, allow to separate, decant the lower carbon tetrachloride layer and shake it with 1 ml of the reagent.

INDICATIONS. A RED colour in the acid layer suggests the presence of dicophane (DDT) or its metabolite, dichlorodiphenyldichloroethylene (DDE). The red colour changes to ORANGE and then to GREEN. Weak PINK colours are given by aldrin, dieldrin, and endrin. A RED colour is also given by dichlorodiphenyldichloroethane (DDD, mitotane) but the colour does not change.

Note. The substance should be tested to ensure that it does not give a colour with *sulphuric acid* alone (p. 145).

Nitrous Acid

METHOD. Dissolve the sample in a minimum volume of water, add an amount of solid sodium nitrite equal in volume to the sample, followed by a few drops of 2M hydrochloric acid, added dropwise.

INDICATIONS. ORANGE or YELLOW colours are given by certain sulphonamides and GREEN, BLUE, or VIOLET colours by certain phenylpyrazolines.

ORANGE	Sulphafurazole
YELLOW	Sulfadoxine, sulfametopyrazine, sulphachlorpyridazine, sulphadimidine, sulphaethidole, sulphamethizole, sulphamethoxazole, sulphamethoxydiazine, sulphamethoxypyridazine, sulphamoxole, sulphaphenazole, sulphapyridine, sulphasomidine, sulphathiazole, sulphinpyrazone
GREEN	Phenazone
BLUE	Dipyrene (transient)
VIOLET	Amidopyrine (transient)

No response is obtained with succinylsulphathiazole, sulfamerazine, sulfaquinoxaline, sulphacetamide,

sulphadiazine, sulphadimethoxine, sulphaguanidine, and sulthiame, nor with propylphenazone.

Palladium Chloride

REAGENT. Dissolve, with the aid of heat, 0.1 g of palladium chloride in 5 ml of 2M hydrochloric acid and dilute the solution to 100 ml with water. Mix together equal volumes of this solution and of 2M sodium hydroxide. The mixed reagent is stable for several weeks.

METHOD. Mix the sample with 1 ml of the reagent and heat at 100° in a water-bath for 2 minutes. A blank solution should be treated similarly at the same time.

INDICATIONS. RED, ORANGE, YELLOW, BROWN, or BLACK colours are given by aliphatic compounds which have a sulphur atom in the chain, and by aromatic compounds which have a sulphur atom in the side-chain. However, no colour is given when an S-alkyl chain is present, unless the chain is terminated by an halogenated group.

No response is obtained if the sulphur is in a group linking two rings. Reducing agents such as ascorbic acid, chloral hydrate, chloroform, and glucose, and compounds containing a chain with a hydrazine link ($-\text{NH}-\text{NH}-$, $-\text{NH}-\text{NH}_2$), give a translucent dark GREY or BLACK colour, but do not give the gradual yellow to orange to brown colour which is seen with sulphur-containing compounds. Compounds containing adjacent hydroxyl groups on an aromatic ring give ORANGE colours turning BROWN.

RED	Gloxazone
ORANGE	Adrenaline (\rightarrow brown), benserazide (\rightarrow brown), bitoscanate, captopril, carbidopa (\rightarrow brown), carbimazole, disulfiram, dobutamine (\rightarrow brown), ecothiopate, isotharine (\rightarrow brown), levodopa (\rightarrow brown), methallibure, methimazole, polythiazide, rimiterol, thiacetazone, thiopentone
Brown-orange	Demeton-S
YELLOW	Clindamycin, dazomet, dimercaprol, dimethoate, methisazone (\rightarrow orange \rightarrow brown), penicillamine
Orange-yellow	Thialbarbitone
BROWN	Ambazone, azinphos-methyl, dihydrostreptomycin (slow), ethionamide, malathion, noxythiolin, parathion, phosalone, prothionamide, spironolactone, thiram
Orange-brown	Chlorthiamid, diazinon, disulfoton, fenitrothion, formothion, phorate, vamidothion
Black-brown	Di-allate, dichlofluanid, tri-allate
GREY	Chlorfenvinphos

BLACK

Ascorbic acid, captan, chloral hydrate, chloroform, mebanazine, nifuratel, phenelzine, procarbazine, sulphasalazine, sulphurea, trichlorfon

Phosphorus Test

METHOD. To the sample add 0.5 ml of *nitric acid* and 0.2 ml of *sulphuric acid*, heat at 100° in a water-bath for 30 minutes, cool, add 1 ml of a 10% solution of ammonium molybdate, and replace in the water-bath at 100° for 5 minutes. A blank solution should be treated at the same time. For some compounds, the reaction may occur after shorter heating times than those stated above.

INDICATIONS. A bright **YELLOW** solution or precipitate indicates the presence of phosphorus and suggests an organophosphorus pesticide, especially if the sample is a water-immiscible liquid. Cyclophosphamide and triclofos also react.

Potassium Dichromate

METHOD 1. Dissolve the sample in 0.5 ml of 2M hydrochloric acid and add a few crystals of potassium dichromate with shaking.

INDICATIONS. An immediate **BROWN** colour, or a **GREEN** colour changing to **BROWN**, indicates the presence of an aminophenol or of a phenol having two or more hydroxy groups in adjacent positions on the ring. Monophenols, halogenated phenols, and phenols with hydroxyl groups *meta* to each other react more slowly or not at all.

RED	Carbidopa
YELLOW (→ BROWN)	Phenol (2 min)
GREEN (→ BROWN)	Adrenaline, dopamine, hexoprenaline, isoetharine, isoprenaline, levodopa, methyldopa, methyldopate, noradrenaline, rimiterol
Blue-green	Aniline (2 min)
BROWN	Benserazide, <i>o</i> -cresol (30 s), <i>m</i> -cresol (2 min), orciprenaline (slow), protokylol (→ red-brown on warming), terbutaline (slow)
Green-brown	Dobutamine

METHOD 2. If the sample is a liquid, add 1 to 2 drops to 1 ml of water followed by 1 ml of a saturated solution of potassium dichromate in 50% v/v sulphuric acid.

INDICATIONS. A **GREEN** colour is given by acetaldehyde, ethanol, isopropyl alcohol, methanol, and propanol.

Schiffs Reagent

REAGENT. Dissolve 0.2 g of basic magenta (fuchsin, CI 42510) in 120 ml of hot water, cool, add 20 ml of a 10% solution of sodium hydrogen sulphite and 2 ml of *hydrochloric acid*, and dilute to 200 ml. Store at 4°, protected from light.

METHOD. Add the sample to 1 ml of the reagent.

INDICATIONS. A **VIOLET** colour indicates the presence of an aliphatic aldehyde. The longer the carbon chain length and especially if it is branched, the weaker the response to the test.

Simon's Test

REAGENT. Dissolve 1 g of sodium nitroprusside in 50 ml of water and add 2 ml of acetaldehyde to the solution with thorough mixing.

METHOD. Add the sample to 1 ml of the reagent.

INDICATIONS. A **BLUE** colour indicates a secondary aliphatic amine or an unsubstituted heterocyclic amine as its free base.

Sodium Dithionite

REAGENT. A 5% solution of sodium dithionite in a 10% solution of sodium hydroxide.

METHOD. Apply the reagent to the sample either on a white tile or as a solution in a test-tube. A blank solution should be treated similarly at the same time.

INDICATIONS. Colours are produced by bis(pyridyl) compounds.

GREEN	Diquat
BLUE	Paraquat

Dark colours are likely to be given by certain metallic solutions because of reduction.

Sodium Nitroprusside

REAGENT. A 1% solution of sodium nitroprusside.

METHOD 1. Add the sample to 2 ml of the reagent followed by 1 drop of 2M sodium hydroxide.

INDICATIONS. **RED** or **ORANGE-RED** colours are given by acetaldehyde and by ketones containing at least one alkyl group.

METHOD 2. Mix the sample with a minimum volume of 2M sodium hydroxide, evaporate to dryness, dissolve the residue in 2 drops of water, and add 0.5 ml of the reagent.

INDICATIONS. A **VIOLET** colour is given by substances containing labile sulphur in the molecule and by unsubstituted dithiocarbamates.

METHOD 3. Carry out Method 2, above, but after

evaporation to dryness heat the residue until it is yellow or orange in colour before proceeding. INDICATIONS. A VIOLET colour is given by certain substances containing labile sulphur which do not react to Method 2, e.g. chlormethiazole, lincomycin, and monosulfiram.

Sodium Picrate

REAGENT. To a saturated solution of picric acid add sufficient sodium carbonate to make the solution strongly alkaline.

METHOD. Mix the sample with a little manganese dioxide and heat to dull redness whilst holding a piece of filter paper, impregnated with the reagent, in the vapours issuing from the tube.

INDICATIONS. The yellow colour of the filter

paper changes from ORANGE to BROWN-ORANGE and then to ORANGE-RED or RED in the presence of cyanide. Positive results are given by compounds containing cyanide groups, e.g. cimetidine, diphenoxylate, and isoaminile.

Sulphuric Acid

METHOD. Apply *sulphuric acid* directly to the sample on a white tile or in a test-tube.

INDICATIONS. A range of colours is obtained with compounds of various types. Steroids give ORANGE or YELLOW colours, many of which fluoresce under ultraviolet light (350 nm) either immediately or after dilution (see below). Thioxanthenes give RED or ORANGE colours which fluoresce under ultraviolet light (350 nm).

RED	Caramiphen (when warmed), danthron, fenitrothion, mequitazine (slowly at 100°), methacycline, metopimazine, nuarimol, pipoxolan
Orange-red	*Oxprenolol, quinomethionate
Violet-red	Morantel, oxytetracycline
PINK	Doxylamine, indapamide (slow)
ORANGE	Alprenolol, amitriptyline, benactyzine, benzilium, benzquinamide, benzyl nicotinate, *chlorprothixene, clidinium, *clopenthixol, cyclothiazide (→ red-brown), diethylthiambutene, diphenamil, diphenhydramine, diphenidol, doxepin, *flupenthixol, indomethacin, mazindol, mebanazine, mecoprop, methapyrilene, methindazole, *methixene, methyclothiazide, methylpiperidyl benzilate, naproxen, nefopam, nifedipine, nortriptyline, orphenadrine, penthienate methobromide, polythiazide, pyrantel (→ violet), rotenone, *thiothixene, tofenacin
YELLOW	Acebutolol, amiloride, amiodarone, benzthiazide, broxaldine, broxyquinoline, cinchophen, clefamide, clemastine (green rim), cyclopenthiazide, diphenadione, doxycycline, enoxolone, fenbufen, frusemide, halquinol, *hydroquinidine, *hydroquinine, lorazepam, methyl benzoate, 5-methyltryptamine, α-methyltryptamine, N-methyltryptamine, metolazone, minocycline, piperacetazine (→ red), procyclidine, *quinidine, *quinine, rimiterol, salbutamol, salinazid, sodium cromoglycate, trichlormethiazide, veratrine (→ violet), zomepirac
Orange-yellow	Ethyl biscoumacetate, hexoprenaline, pizotifen (→ violet)
GREEN	Phenothiazine, protriptyline
BLUE	
Brown-blue	Chlortetracycline, demeclocycline
VIOLET	Bendrofluazide, chlorotrianisene, *chromonar, clofazimine, cyproheptadine, dothiepin, mesoridazine (→ blue), methylenedioxymphetamine, nicergoline, perazine, phenindione, rolitetracycline, tetracycline
Red-violet	Trifluomeprazine
BROWN	Chelidonine, sulindac
Red-brown	Lymecycline
Orange-brown	Biperiden, ouabain (slow)
Yellow-brown	Tylosin (slow)
Grey-brown	Octaphonium
BLACK	
Blue-black	Clomocycline

* Fluoresce under ultraviolet light (350 nm)

REACTIONS OF STEROIDS WITH SULPHURIC ACID

<i>Initial colour</i>	<i>Compound</i>	<i>Fluorescence at 350 nm</i>	<i>Fluorescence after dilution</i>
RED			
Orange-red	Dienoestrol	nil	nil
	Dimethisterone	nil	yellow
	Mestranol	yellow	orange (pink in daylight)
PINK			
Orange-pink	Dexamethasone	nil	nil
	Prednisolone	nil	green (red in daylight)
ORANGE	Beclomethasone (slow)	nil	nil
	Cholesterol	nil	white
	Dydrogesterone	green-yellow	green-yellow

Pink-orange	Betamethasone	nil	nil
Green, orange (dichroic)	Hydrocortisone	green	green
YELLOW	Alphadolone	nil	nil
	Androsterone	nil	white
	Carbenoxolone	nil	yellow
	Cortisone	green	green
	Deoxycortone	green-yellow	yellow (violet in daylight)
	Enoxolone	nil	green-yellow
	Fluocinolone	green	quenched
	Fluoxymesterone	green	quenched
	Flurandrenolone	green	quenched
	Hydroxyprogesterone	green	quenched
	Oestradiol	green	green (orange in daylight)
	Prednisone	green	green
	Progesterone	green	quenched
Orange-yellow	Fluocortolone	(weak)	(weak)
Green-yellow	Oestrone	green	green-yellow (orange in daylight)
NO COLOUR	Oestriol	yellow-green	quenched (orange in daylight)
	Testosterone	green	nil

Sulphuric Acid-Fuming Sulphuric Acid

REAGENT. Mix together 7 ml of *sulphuric acid* and 3 ml of *fuming sulphuric acid*.

METHOD. Dissolve the sample in a minimum volume of toluene and add 1 or 2 drops of the reagent.

INDICATIONS. A RED colour appearing in the lower acid layer indicates the presence of dieldrin (colour develops quickly) or aldrin (colour develops slowly). A PINK-ORANGE colour is obtained with endrin.

Thalleioquin Test

METHOD. Dissolve the sample in a minimum volume of 2M hydrochloric acid, add 2 drops of *bromine solution*,

place 1 drop of the mixture on a piece of filter paper, and expose the paper to ammonia fumes.

INDICATIONS. A GREEN colour indicates the presence of a quinine-type structure, e.g. hydroquinidine, hydroquinine, quinidine, and quinine. Cinchonidine and cinchonine do not respond.

Vanillin Reagent

REAGENT. Dissolve 1 g of vanillin in 20 ml of *sulphuric acid*, warming if necessary.

METHOD. Add 2 drops of the reagent to the sample, heat in a water-bath at 100° for 30 seconds, and note any colour which is produced. Dilute the

cooled mixture by adding a few drops of water and note any change of colour.

INDICATIONS. Many compounds of different chemical structure react with this reagent. However, for barbiturates, the reaction appears to be a steric phenomenon which depends on the structure of the side-chain at the 5-position. Dark colours which are either dispelled or changed to violet, blue, or green by dilution are produced when either side-chain is greater than 2 carbon atoms in length, or contains a cycloalkene ring. Branching can be proximal to the pyrimidine ring but not distal. No colour is obtained if both side-chains are less than 3 carbon atoms in length, or if either is branched distally or contains an aryl nucleus. Long, straight, saturated chains also appear to hinder reaction.

Hydroxy-barbiturates give positive responses, but bemegride, glutethimide, phenytoin, and primi-done do not respond.

REACTIONS OF BARBITURATES WITH VANILLIN REAGENT

<i>Colour after heating</i>	<i>Compound</i>	<i>Colour after dilution</i>
Brown-orange	Allobarbitone	violet (transient)
	Brallobarbitone	brown-orange
	Talbutal	violet
	Thialbarbitone	violet (transient)
BROWN	Hexobarbitone	violet
Violet-brown	Methohexitone	colourless
	Vinbarbitone	colourless
	3'-Hydroxypentobarbitone	colourless

<i>Colour after heating</i>	<i>Compound</i>	<i>Colour after dilution</i>
Brown-orange	Allobarbitone	violet (transient)
	Brallobarbitone	brown-orange
	Talbutal	violet
	Thialbarbitone	violet (transient)
BROWN	Hexobarbitone	violet
Violet-brown	Methohexitone	colourless
	Vinbarbitone	colourless
	3'-Hydroxypentobarbitone	colourless

No response is obtained with amylobarbitone, aprobarbitone, barbitone, butobarbitone, enallyl-propymal, hexethal, ibomal, idobutal, metharbitone, methylphenobarbitone, nealbarbitone, phenobarbitone, or phenylmethylbarbituric acid. With the cold reagent, an ORANGE colour is produced by pentobarbitone, quinalbarbitone, and thiopentone, and a BROWN colour by cyclopentobarbitone.

Immunoassays

M. J. Stewart

Immunoassays now have a firm place among routine methods for the analysis of drugs in biological fluids. The popularity of radioimmunoassays has been ensured by the high sensitivity, the lack of necessity for a preliminary extraction stage, and the applicability to the analysis of large numbers of samples. The more recent developments, notably in optical immunoassays, also offer a variety of rapid methods which are suitable for emergency analysis and for therapeutic drug monitoring.

BASIC PRINCIPLES OF IMMUNOASSAYS

The immunoassay technique uses an antibody specific for the drug being assayed, and a labelled form of the same drug. The method depends on the ability of the drug being assayed to compete in the reaction between the antibody and the labelled drug. Ideally the labelled drug should be such that it takes part in the reaction as though it were the unlabelled drug, but this ideal is not always fully satisfied. The label may be a particular radioisotope, an active enzyme, or a fluorescent label, incorporated synthetically.

The basic technique consists of placing a fixed quantity of the antibody in a tube together with a fixed quantity of the labelled drug, and the test sample containing the drug to be assayed. The specific binding sites on the antibody bind both the labelled drug molecules (Drug*), and the unlabelled drug molecules present in the test sample. The proportion of labelled drug molecules bound is inversely proportional to the number of unlabelled drug molecules.

A suitable analytical measurement is then made and the results are compared with a calibration curve. In radioimmunoassays, the measurement is of radioactivity. However, there is no difference between the signals produced by bound and free

labelled-drug so that it is necessary to separate the two before measurement (p. 150). These assays are referred to as *heterogeneous immunoassays*. Since the amount of radiolabelled drug remaining in the solution, or bound to the antibody, depends on the concentration of unlabelled drug, measurement of the radiolabelled drug in either the bound or the free form will give an estimation of the original concentration of unlabelled drug. A calibration curve is constructed in which the percentage of radiolabelled drug bound to the antibody is plotted against the concentration of drug (Fig. 1). Other ways of generating standard curves are described later.

Fig. 1. Calibration curve for an immunoassay.

In assays where the drug is labelled with an enzyme or a fluorescent substance, the measurement is of an optically detected change such as ultraviolet absorption, fluorescence, or luminescence. In these optical immunoassays, there is a difference between the signals generated by the free and the bound labelled-drug. Thus, no separation step is necessary and they are referred to as *homogeneous immunoassays*. The difference between the signals may arise because the signal is suppressed on binding, produced on binding, or altered on binding.

Homogeneous assay systems have obvious advantages over radioimmunoassays, in that no separation stage is necessary and the difficulties of working with radioisotopes are avoided. However, they have the disadvantage of reduced sensitivity because the optical signal is measured in the presence of the original biological fluid, albeit diluted. Consequently, commercial homogeneous optical immunoassays are applicable only to measurements of drugs down to a few ng/ml. For measurement of concentrations below this, radioimmunoassay remains the current method of choice, although heterogeneous optical immunoassays could offer similar sensitivity.

Production of the Antibody

In general, drugs have molecular weights which are too low for them to act as antigens, i.e. to produce antibodies when injected into an animal. It is necessary, therefore, to couple the drug to a larger molecule which is usually a protein. The most commonly used protein is albumin (molecular weight approximately 70 000), taken from a species other than that in which the antibody is to be raised.

Before the antigen is prepared and purified, it is necessary to decide on the required specificity. In some cases, there may be advantages in producing an antibody with low specificity in order to detect all of a family of drugs.

The coupling of a drug to a protein such as bovine serum albumin may be carried out by a variety of methods depending on the reactive sites on the drug, and the specificity required. As an example, the production of an antibody to pentobarbitone is shown in Fig. 2. If antigen A is used, the antibody which is produced is insensitive to changes at position 5 and will therefore react, not only with pentobarbitone, but also with other 5,5-disubstituted barbiturates such as barbitone, phenobarbitone, and 5-hydroxy metabolites. However, it will not react with drugs or metabolites which have modifications in positions 1 or 3. If a more specific antibody is required, then a longer chain length between position 5 and the protein must be used, or the protein should be linked to an alternative position on the ring, as illustrated for antigen B.

Injections into the animals are made with the antigen in Freund's complete adjuvant. This adjuvant contains a neutral detergent, paraffin oil, and killed mycobacteria; its purpose is to release the antigen slowly and to speed the production of antibodies by stimulating the immunological response of the animal. Serial multiple injections of small amounts of antigen provide the most satisfactory results. If large quantities of antiserum are required, then large animals such as sheep are preferred. However, some animals provide antisera of a higher titre which may be used at a greater dilution. After about 12 days, samples of blood are withdrawn for testing. When

Fig. 2. Different antigens used to produce antisera for pentobarbitone.

a high concentration of antibody is detected, a large volume of blood is removed and the serum is separated (antiserum).

Determination of Antibody Titre. An appropriate dilution of the serum containing the antibody is used, depending on the quantities of drug to be assayed. The appropriate quantity of labelled drug is chosen, depending on the requirements of sensitivity, accuracy, and ease of sample preparation, and serial dilutions of the original animal serum are made to obtain a titre such that approximately 50% of the labelled drug is bound to the antibody (Fig. 3). This dilution of the serum is then made and used in the immunoassay. If only a low titre is obtained, even after several booster shots have been given, a new batch of animals or different animals can be tried.

Fig. 3. Antibody dilution curve.

Antibodies vary considerably in their shelf-lives, but they are usually of the order of several years if frozen or freeze-dried.

The avidity (K) of the antibody is the equilibrium constant in the reaction $\text{Ag} + \text{Ab} \rightleftharpoons \text{AgAb}$, where Ag is the drug and Ab is the antibody. Thus

$$K = \frac{[\text{AgAb}]}{[\text{Ag}][\text{Ab}]}$$

It is calculated by the use of a Scatchard plot in which the concentration of bound drug is plotted against the ratio of bound to free drug, after correcting for non-specific binding. The steeper the slope, the lower is K (Fig. 4), and the intercept on the x -axis gives the total concentration of the antibody binding sites (mol/litre).

Fig. 4. Scatchard plot of drug bound to antibody.

It is calculated by the use of a Scatchard plot in which the concentration of bound drug is plotted against the ratio of bound to free drug, after correcting for non-specific binding. The steeper the slope, the lower is K (Fig. 4), and the intercept on the x -axis gives the total concentration of the antibody binding sites (mol/litre).

The specificity of the antiserum is determined by comparing the binding of the drug to which the antiserum is directed with the binding of other drugs and metabolites. The extent to which other drugs and metabolites interfere is known as the *cross-reactivity*.

Separation of Bound and Unbound Drug

Before an analytical measurement can be made, it is necessary to separate bound drug from unbound drug in radioimmunoassays and also, if the highest sensitivity is required, in optical immunoassays.

The separation step gives rise to some of the greatest imprecision, and can be greatly influenced by endogenous components in the biological fluid; a system which works well with plasma may not give an efficient separation in urine. These effects can be reduced by the use of high dilutions of the biological fluid but sensitivity is also reduced.

Adsorption with charcoal has been widely used as a separation technique, but a variety of more precise and simpler methods are now available (Table 1). The methods of choice are the double antibody technique, and solid-phase systems. These are also the most easily automated.

Table 1. Methods of separating bound and free drug

Method	Agent used
Adsorption of free drug	Charcoal coated with dextran
	Porous beads
	Filter paper
	Ammonium sulphate
Precipitation of drug-antibody complex	Double antibody
	Polyethylene glycol
	Antibody bound to the walls of tubes or to plastic beads or rods
Immobilised antibody	Magnetic particles

Charcoal Adsorption. This adsorbs the free fraction and the charcoal can be separated by centrifugation or by filtration. Obviously if too strong an adsorbent is used, e.g. activated charcoal, it may also adsorb the bound fraction. To prevent this, the charcoal is often coated with dextran or gelatin.

Double Antibody Technique. Although the drug-antibody complex is large it is still soluble. It can be converted into an insoluble form, which can be centrifuged, by the addition of a second antibody (the precipitating antibody) raised against the globulins of the animal in which the first antibody was raised. The free fraction is then simply decanted out of the tube.

Solid-phase Systems. The antibody to the drug is covalently attached to the inside walls of a plastic tube or to solid particles or rods. After incubation, the drug-antibody complex remains attached to the tube or to the particles (Fig. 5). The free drug may then be discarded and the solid phase washed. It is then possible either to measure the amount of bound labelled drug directly, e.g. by counting gamma emission, or, in the case of optical immunoassays, to dissociate the bound labelled drug, resuspend it in a solution, and measure the optical signal.

Magnetic Particles. Separation may be achieved by

Fig. 5. Solid-phase immunoassay.

using an antibody bound to magnetic particles. This method has been used in fluoroimmunoassays and is described on p. 155.

Techniques for the coupling of antibodies to cellulose particles or tubes were initially unreliable, time-consuming, and hazardous as they involved toxic reagents such as cyanogen bromide. A simple and convenient method is now available which employs 1,1-carbonyldi-imidazole to couple antibody to microcrystalline cellulose.

RADIOIMMUNOASSAY

The principal components in radioimmunoassay (RIA) are a drug labelled with a suitable radioisotope, an antibody specific to that drug, and the assay sample. The drug-antibody complex (bound drug) must be separated from the free drug in the later stages of the assay.

The amounts of antiserum (containing the antibody) and of labelled drug are chosen such that the radioactivity is divided approximately equally between the bound and free fractions. Drug from the sample competes with the radiolabelled drug for the antibody binding sites. After allowing an appropriate time for equilibration (incubation period), the bound and free phases are separated. The radioactivity of either phase may then be measured and plotted as described below. Each assay must include standards covering the range of concentrations being measured, and blank solutions; all assays should be carried out in duplicate.

RADIOISOTOPE-LABELLING OF DRUGS

Tritium (^3H), carbon-14 (^{14}C), and iodine-125 (^{125}I) are the three isotopes used in radioimmunoassays; Table 2 gives their radioactive properties and some counting data. The manufacture of ^3H - and ^{14}C -labelled drugs can be carried out using the normal synthetic route of the drug or, in the case of tritium, by hydrogenation of the molecule or by exchange with tritiated water.

Table 2. Properties of radioisotopes used in RIA

Element	Symbol	Half-life	Radiation emitted	Energy keV	Counting efficiency %	Back-ground counts/minute
Tritium	^3H	12.3 years	Beta	18	60–65	20–30
Carbon-14	^{14}C	5730 years	Beta	155	93–98	20–30
Iodine-125	^{125}I	60 days	X and Gamma	27	60–65	20–30

Since few drugs contain iodine it is necessary to add iodine to the molecule, e.g. *ortho* to a phenolic group, or, if this is not possible, to iodinate a suitable derivative of the drug. For example, a tyrosine derivative of digoxin can be made from digoxigenin (via the 3 position and a succinic acid linkage) and lysergide can be bonded to a synthetic polymer (L-glutamine-L-lysine-L-alanine-L-tyro-sine)_n. In the above cases the tyrosyl group can then be iodinated in the *ortho* position to the phenol. The iodination is carried out with a solution of radioactive sodium iodide in an aqueous phosphate buffer containing chloramine, and the radiolabelled drug is separated from the components of the reaction mixture by gel filtration, adsorption chro-matography, or electrophoresis.

Tritium-labelled assays are more common than carbon-14 assays which are often less sensitive; an exception is the ^{14}C -labelled assay for paraquat (D. Fatori and W. M. Hunter, *Clinica chim. Ada*, 1980, 100, 81-90; T. Levitt, *Proc. Analyt. Div. Chem. Soc.*, 1979, 16, 72-76) which has proved useful in emergency cases and has acceptable accuracy despite a very short counting period of 1 minute.

MEASUREMENT OF RADIOACTIVITY

Two methods of measuring radioactivity are used in RIA, namely, liquid-scintillation counting and γ -counting. In liquid-scintillation counting, the radioisotope is placed in a scintillation mixture and the emission of visible light is measured; fresh vials containing the scintillation mixture are required for each measurement. γ -Counting is usually performed in a crystal-scintillation counter; the vial containing the radioisotope is placed directly into the counter and counted for a fixed length of time. β -Radiation can only be measured by means of liquid-scintillation counting whereas γ -radiation may be measured by either crystal-scintillation or liquid-scintillation counting.

The relative advantages of using a β -emitter (^3H and ^{14}C), rather than a γ -emitter are:

1. ^3H and ^{14}C have long half-lives compared to ^{125}I and thus have relatively long shelf-lives.

2. Radiation hazards from β -emitters with low specific activity are minimal.

3. ^3H and ^{14}C may be incorporated into the drug molecule without altering its molecular arrangement. Thus the labelled drug binds to the antibody in an identical manner to the unlabelled drug; this may not be true if the iodinated form of the drug is used.

4. The radioisotopes may be incorporated into the molecule during synthesis, avoiding further manipulation (as in iodination) which may damage it.

The advantages of using a γ -emitter, e.g. ^{125}I , are:

1. Measurement of γ -rays by crystal-scintillation counting is much cheaper and quicker than liquid-scintillation counting.

2. Extraction and purification of the sample containing ^{125}I is not required as γ -rays penetrate coloured solutions and soft tissue with negligible loss of energy. In the case of β -emitters, the scintillation solution must be colourless or quenching corrections must be applied.

3. Higher specific activities can be obtained with ^{125}I labels and therefore the counting time can be reduced, e.g. from 20 minutes to 1 minute. (Specific activity is the radioactivity per unit mass of drug, e.g. MBq/ μg , where 1 Bq=1 disintegration/second = 2.7×10^{-11} Ci.) Approximately 5000 atoms, 100 atoms, and 1 atom of ^{14}C , ^3H , and ^{125}I , respectively, are needed to produce the same number of disintegrations per minute because of the different half-lives.

OPTICAL IMMUNOASSAY

Optical immunoassays have a number of advantages over radioimmunoassays (Table 3), mainly because the reagents are stable and homogeneous assays can be produced simply. Various labels can

Table 3. Comparison of radioimmunoassays and homogeneous optical immunoassays

	Radio-immuno-assay	Optical immuno-assay
Special safety precautions	yes	no
Simple labelling procedures	yes	yes
Limited shelf-life of labelled drug	yes	no
Separation step necessary	yes	no
Measurement time	moderate	short
Precision	moderate	high
Sensitivity	1 pg/ml	1 ng/ml
Automation	partial	full

be used including enzymes, and fluorescent or chemiluminescent labels.

Commercial optical immunoassays are usually homogeneous, but for the highest sensitivity, separation of bound drug from unbound drug is required.

Enzyme Immunoassays

The principal components in enzyme immunoassays are a drug labelled with a specific enzyme, an antibody specific to the drug, a substrate capable of producing a measurable optical signal when catalysed by the enzyme, and the sample for assay. When the enzyme-labelled drug is bound to the antibody, the activity of the enzyme is inhibited or reduced (Fig. 6). The drug in the sample displaces a proportion of the enzyme-labelled drug from the antibody, thus activating the enzyme which then acts on the substrate and changes its optical properties (ultraviolet absorption, turbidity, etc.). The change in enzyme activity and hence the change in the optical signal is proportional to the amount of free drug added to the drug-enzyme-antibody complex. The optical signal produced is amplified because the displaced enzyme catalyses numerous conversions of the substrate.

Fig. 6. Mechanism for a homogeneous enzyme immunoassay.

Enzyme immunoassays are also amenable to kinetic measurement. The rate of substrate conversion is proportional to the enzyme activity. Hence an analysis, for example, of the rate of change of ultraviolet absorption may be useful for samples which have a high background absorption.

ENZYME-LABELLING OF DRUGS

The addition of an enzyme molecule to a drug increases the molecular weight considerably but, despite this, it is possible to produce enzyme-labelled drugs which bind to the antibody in a similar manner to the unlabelled drug within a period of only one or two minutes. The simplest linkages are made through —COOH or —NH_2 groups on the drug molecule.

A variety of enzymes is employed, such as horseradish peroxidase, bacterial glucose-6-phosphate dehydrogenase (G6PDH), and muramidase (lysozyme). The choice of enzyme depends on the reaction and hence the signal to be measured. Interference from endogenous enzyme activity must be avoided. This may be done by simply ensuring that enzymes of similar substrate-specificity as the label are not present in the sample. Another approach is illustrated by the use of G6PDH as the label. The enzyme is derived from bacteria and requires nicotinamide-adenine dinucleotide (NAD) as the coenzyme. Interference from human G6PDH in serum is avoided because that requires nicotinamide-adenine dinucleotide phosphate (NADP) as the coenzyme.

The method of linking the enzyme to the drug must also be chosen carefully. Antibodies raised by the injection of a drug-protein conjugate may be directed to the drug-protein linkage as well as to the drug. If the enzyme is linked to the drug in the same manner, the enzyme-labelled drug will bind more avidly to the antibody than the unlabelled drug, thus invalidating the assumption that the binding characteristics of the labelled and unlabelled drug are similar. In order to overcome this problem, different linkages should be used for binding drug to protein and drug to enzyme.

Enzyme immunoassays have been widely adopted because the method is extremely rapid and simple, and therefore enables drug analyses to be carried out in a variety of locations. The sample volume required is about 10 to 50 μl , thus making analyses possible on capillary specimens or on samples from neonates. The technique is available in kit form, with high quality reagents and all the necessary standard solutions, thus reducing the requirements for operator skill. In cases where large numbers of analyses are required, the assays may be carried out on a variety of automated analysers.

The disadvantages of enzyme immunoassays lie in their cost and relative insensitivity compared to radioimmunoassays.

Enzyme immunoassays which utilise ultraviolet

absorbance as the measured end-point may be given increased sensitivity if the end-point is converted to a fluorescent measurement.

Fluoroimmunoassays

A variety of immunoassay techniques employ changes in the fluorescent properties of molecules to measure drug concentrations. Labelling of drugs with such molecules avoids the hazards of working with radioisotopes. Fluoroimmunoassays (FIA) also offer enhanced sensitivity in comparison to enzyme immunoassays; they may be homogeneous or heterogeneous.

The choice of fluorophore has a considerable effect upon the sensitivity of the assay, and depends on the assay conditions. Ideally, the fluorophore should have a large Stokes shift (p. 233), it should be easily differentiated from endogenous fluorophores, and should be capable of being coupled simply to the drug. Fluorescein satisfies all these requirements and is the most popular fluorophore used.

Homogeneous Fluoroimmunoassays

In commercial *substrate-labelled fluoroimmunoassay* an enzyme is used to release the fluorophore from the labelled drug molecule. Fig. 7 illustrates the mechanism. One such technique requires a drug labelled with the fluorogen β -galactosyl-umbellifer-one (enzyme substrate), a drug-specific antibody, the enzyme β -galactosidase, and the sample. The enzyme hydrolyses the β -galactosyl-umbelliferone linkage to yield a fluorescent species. However, the enzyme cannot gain access to the labelled drug when it is bound to the antibody. Drug from the sample competes with the labelled drug for the antibody binding sites and any unbound labelled drug is hydrolysed by the enzyme. The intensity of fluorescence is therefore proportional to the amount of drug present in the sample.

Another technique, called *fluorescence polarisation immunoassay*, exploits the difference in rotation of bound and free fluorophore-labelled drug. Polarised light incident on a fluorophore-labelled molecule produces emission of plane-polarised light. However, as the labelled drug molecule rotates during the period between absorption and emission of light, the amount of polarised light emitted in any given plane is reduced. Binding of the molecule to antibody reduces the rotation and this increases the intensity of polarised light emitted in a particular plane.

The assay requires the use of a polarising attachment to the fluorimeter, containing liquid crystal

Fig. 7. Mechanism for a substrate-labelled fluoroimmunoassay.

polarising filters which are capable of measuring the emitted light in two planes at 90° to one another. Polarisation is measured in arbitrary units.

$$\text{Polarisation} = \frac{\text{Vertically polarised light} - \text{horizontally polarised light}}{\text{Vertically polarised light} + \text{horizontally polarised light}}$$

polarising filters which are capable of measuring the emitted light in two planes at 90° to one another. Polarisation is measured in arbitrary units.

Thus polarisation is directly proportional to the amount of bound labelled drug and inversely proportional to the amount of free drug present. Since a change in the polarisation of the light is measured, the interference from non-specific fluorescence is minimised. However, a blank correction may be needed for drugs present in low concentrations e.g. digoxin.

All of the homogeneous fluoroimmunoassay systems suffer from the possibility of background interference from other drugs and metabolites. Enzyme labels may be inhibited by endogenous molecules, and there may be fluorescence enhancement or quenching from the same sources. This may be overcome by careful choice of assay conditions and the use of high dilutions of the biological sample.

Heterogeneous Fluoroimmunoassays

The most effective method of removing background interference is to use a heterogeneous assay such as that shown in Fig. 8. The assay uses a fluorophore-labelled drug, an antibody bound to magnetic particles, and the assay sample. Drug in the sample competes with the labelled drug for binding to the antibody. The proportion of labelled free drug is related to the amount of drug in the sample. Antibody-bound drug is separated from the free drug by applying a magnetic field. The free drug (labelled and unlabelled) in the supernatant liquid is decanted and discarded. The bound drug is eluted with a buffer, resuspended to separate the bound drug from the antibody, the antibody is sedimented by application of the magnetic field, and the fluorescence in the supernatant liquid is determined. Fluorescence intensity is inversely related to the amount of drug in the sample.

Separation of bound and free drug using antibody bound to magnetic particles avoids centrifugation, is quicker, and allows direct measurement of fluorescence in the supernatant liquid by simply sedimenting the antibody at the bottom of the assay tube by means of a magnetic field.

Other means of separation, such as ammonium sulphate precipitation and bonding of the antibody to cellulose beads may also be used for heterogeneous fluoroimmunoassays.

Fig. 8. Heterogeneous fluoroimmunoassay using magnetic particle separation.

Fluoroimmunoassays have a number of advantages. There is a wide variety of assay types with choice of fluorophores with different wavelengths of excitation and emission. The instrumentation is simple, there is high precision of measurement of the signal, and the sensitivity is high. The reagents are economical and stable, and the method is applicable to homogeneous and heterogeneous systems.

Disadvantages of fluoroimmunoassays include interference from endogenous fluorophores, quenching of signals, and non-specific binding.

Luminescence Immunoassays

Immunoassays which employ drugs labelled with a substance which emits light when activated have been developed. The basic principles of these assays are similar to those of fluoroimmunoassays. The use of luminescent labels, however, has the advantage that light is not introduced into the system, so giving an increase in sensitivity.

Luminescence is produced chemically by molecules such as luminol following treatment with a peroxide, or enzymatically from luciferon after reaction with luciferase. Two typical reactions are given in Fig. 9. The coupling of luminescent molecules to drugs is similar to the procedure employed for fluorescent labels.

Fig. 9. Typical chemiluminescence reactions used in immunoassays.

The quantum yield of luminol is relatively low and developments now in progress use the luminescent light source to excite a secondary fluorescent molecule. Luminescence, like fluorescence, is susceptible to quenching by a variety of drugs and endogenous compounds.

Luminescence is produced rapidly over a very short time-scale (300 ns), and instrumentation is required to allow reproducible and rapid mixing, coupled with accurate integration of the signal over a short time interval. Sensitivities of the order of fg/ml are theoretically possible, allowing the assay of highly diluted specimens and thus minimising interference. Enzymes and fluorophores represent the most popular optical labels at present, but there is a wide range of alternative labels such as metal atoms and proteins, which provide alternative methods of quantification.

QUANTIFICATION OF IMMUNOASSAYS

Standardisation

Standard solutions covering the range of expected concentrations should be prepared for each assay. The shape of the calibration curve obtained will differ between batches of antisera. For this reason, manufacturers of kits provide matched standards with each kit. Standards and other reagents from one kit can be used with another kit provided that they are from the same batch, but it is not acceptable to mix standards and reagents from different batches. The implications for in-house methods are that each batch of antiserum must be checked against the standards used for the previous batch, and the reagents must then be tailored to produce an acceptable calibration curve which gives comparable results. It follows that a considerable overlap, and much checking of calibration, is required when either the antiserum or the standards are renewed.

If standards are to be made in-house, they should be prepared in a fluid which is as similar as possible to the fluid being analysed. If human plasma or serum is not available then equine or bovine serum is acceptable. However, such preparations may give spurious results due to endogenous constituents which interfere with the antigen-antibody binding reaction. If pooled human serum or plasma is used, it is possible that drugs such as diazepam may be present. Thus, drug-free human plasma obtained from volunteers is the best medium. Pooled plasma should always be checked for cross-reactivity before being used in the production of standards or quality control materials.

The weighed amount of drug should be dissolved in a suitable solvent, and then mixed with the serum or plasma; care must be taken to ensure complete mixing before packing into vials for storage.

Standard solutions which have been stored frozen should be thawed gently and mixed thoroughly before use. On no account should standard solutions in biological fluids be frozen and thawed on more than one occasion as this can result in the formation of particulate matter which may cause considerable errors. The stability of the drug when stored at different temperatures should be studied, and arrangements should be made to replace expired standards.

As a final consideration, the possibility of the presence of non-specific binding of drugs by plasma proteins and the specific binding by endogenous drug-specific antibodies should be borne in mind when unexpected results are obtained from an immunoassay.

Calculation of Results

The analysis of a series of standards in an optimised immunoassay will give a calibration curve which is sigmoid in shape when binding is plotted against concentration. Such curves are difficult to plot accurately by hand, and reading from them can lead to errors. There are a number of approaches which have been adopted in order to simplify the work of the operator. The curve may be 'linearised' by plotting appropriate functions of the concentration and the measured signal, or a best-fit curve may be generated by means of a computer.

In optical immunoassays, where signal errors are minimised, the tendency has been towards one of a variety of linearised presentations employing specially designed semilogarithmic graph paper. The disadvantage of this technique is that a specific batch of graph paper is required for each batch of reagents. These charts tend to conceal the fact that the precision at the low and high ends of the line is much lower than that at the mid-point. Microprocessors, with curve storage, are now available for several immunoassay systems. These not only save on reagents and operator time, but also minimise errors.

Quality Control

Antisera from different sources differ greatly, depending on the antigen against which they were raised. Antisera produced by a standard method

can be adjusted so as to provide similar reactivity, but material obtained from different manufacturers may show marked differences in specificity. Thus, although an internal quality control scheme may show excellent precision when one set of reagents is employed, comparison with other immunoassays or with non-immunoassay methods may give results which differ markedly.

The assessment of the specificity of an antiserum is the responsibility of those who raise the antiserum and develop the assay. As a basic minimum, it is necessary to check the values obtained from a wide variety of drug-free biological fluids and the cross-reactivity of metabolites and similar drugs. In addition, the effect of pathological concentrations of endogenous metabolites should be assessed; they may not cross-react with the antibody but they may have a significant effect on the binding of the drug to the antibody.

Most commercial kits contain data on cross-reactivity, but some metabolites may not be available for this assessment. In particular, water-soluble conjugates, such as glucuronides and sulphates, are seldom studied. These may not be present in the plasma of healthy persons, but in renal failure they may be present at concentrations which are sufficiently high to give a significant error even if the cross-reactivity is considerably lower than that of the parent drug. For the same reason, reagents prepared and assessed for use in plasma should not be used uncritically for the determination of drugs in urine where concentrations of metabolites may exceed those of the parent drug.

Users of immunoassays should participate in external quality assurance schemes, preferably those using samples obtained from populations of patients (see *Quality Control in Clinical Analysis*, p. 118). Commercial quality control sera are prepared by adding pure drugs to drug-free serum and therefore do not contain metabolites, etc., which could reveal problems associated with non-specificity.

Assuming that accuracy is satisfactory and that interfering factors are minimal, the major problem is the optimisation of precision. The major factors affecting the precision of an immunoassay are shown in Table 4. The problems relating to the initial dilution and sampling are significant and demand the use of partial automation. A range of pipetter-diluters are available which can minimise this source of error. It is useful if all additions and dilutions can be made at only one setting of the syringe. Where changes have to be made, instruments with clearly

marked stepped volumes are preferable to those with continuously variable settings.

Table 4. Factors contributing to imprecision in immunoassays

<i>Factor</i>	<i>Comment</i>
Dispensing errors	Affects all methods; reduced by automation
Binding kinetics	Precision is proportional to the concentration of the drug
Separation of bound and free labelled drug	Applies only to heterogeneous methods
Final measurement of labelled drug	Reproducibility is in the order optical > γ -emitter > β -emitter
Method of plotting curve	Affects all methods; precision lower at the ends of the curves

The effect of temperature on enzyme immunoassays should not be overlooked, and adequate thermo-static control is mandatory. This problem is not met with in other optical immunoassays which gives the latter some advantages.

The final measurement can contribute considerably to imprecision and for optical immunoassays is instrument-related. For radioimmunoassays, considerable improvements in both time and precision may be made by employing γ -labelled drugs and counting in a 16-head γ -counter. Scintillation counters have an accuracy of measurement which is approximately the square root of the total number of counts, e.g. about 1% counting error when measuring 10000 counts.

The measurement of fluorescence offers potentially the most stable end-point but, since fluorescence is related to the intensity of incident light (unlike absorbance), an instrument which continually measures the ratio of emitted to incident light is necessary for the highest precision. Under these circumstances the precision of the final measurement may approach $\pm 1\%$.

Improvements in automation up to and including the final calculation step are leading to continued improvements in precision, both in large batches and for single assays.

Automation

Automated methods have advantages, in that higher precision is often possible by the elimination of operator bias. Semi-automated techniques are, however, widely used in immunoassays in order to

reduce the errors associated with dispensing small volumes of viscous solutions.

A range of pipetter-diluters are available for radioimmunoassays and these are used almost universally, even for small batches. Fully automated RIA systems are available but are only economically viable in major central laboratories. Fully automated systems have the advantage that there is a standardised treatment of tubes at the critical stage of separation of bound and free drug.

Continuous flow systems are also available for RIA. One such system employs an antibody bound to cellulose-coated iron particles which may be removed using a magnetic field. In another, the antibody is bound to the walls of a mixing chamber which is reused after washing. Other continuous flow systems use resin filters which absorb the free drug and allow the bound drug to pass through, or they may use resin beads which bind the antibody-drug complex and are separated from the free drug by filtration.

Homogeneous optical immunoassays are easily automated, and instruments specifically designed for enzyme and fluoroimmunoassay are available. These instruments are capable of rapid analysis of batches as well as of single assays, with standardisation and quality control data held in microprocessors.

APPLICATIONS OF IMMUNOASSAYS

Radioimmunoassay is the method of choice for cardiac glycosides, insulin, lysergide, cannabinoids, and opiates where blood concentrations and/or sample volumes are low. Other applications include screening for drug abuse, the investigation of cases of poisoning, and therapeutic drug monitoring.

Screening for Drug Abuse

Although gas chromatographic methods exist for amphetamines and narcotic alkaloids in urine, quantitative measurement in plasma is a difficult analytical problem. Radioimmunoassay and optical immunoassay methods are available for a variety of these drugs in urine, but there is a wide range of antibodies with different cross-reactivities. Methods for the measurement of these compounds in plasma are restricted to radioimmunoassay because the majority of optical assays are not sufficiently sensitive. Assays employing antibodies of wide specificity are often employed as a means of determining whether one or more of a group of drugs is present. Such assays can be adapted to the

measurement of individual drugs and their metabolites by using fractions collected from an HPLC separation.

Investigation of Poisoning

Most of the commercial immunoassays currently available are designed for the analysis of drugs at concentrations up to 2 or 3 times the therapeutic concentration. These kits may be used on diluted samples from poisoned patients in which there may be concentrations up to 10 or 20 times the therapeutic concentration. However, care should be taken when interpreting results because high concentrations of other drugs or metabolites may be present and these may cross-react. For example, an enzyme immunoassay for benzodiazepines may be used for screening for this group of drugs in cases of overdose, but the presence of up to four pharmacologically active metabolites from one parent drug, each with different cross-reactivities, makes interpretation difficult.

Sometimes a relatively non-specific assay for a group of compounds, e.g. barbiturates, can be used and, if a positive result is obtained, it can be followed by specific analyses for individual barbiturates.

Therapeutic Drug Monitoring

Homogeneous optical immunoassays are ideal for use in therapeutic drug monitoring because their speed and simplicity allow the analysis to be performed sufficiently quickly to permit clinical decisions to be made. This type of analysis has proved most beneficial for the aminoglycoside antibiotics gentamicin, and tobramycin, for methotrexate when used in high dosage, and for theophylline in neonates. For these drugs, the rapid return of accurate results can make a major contribution to patient care.

Those drugs for which immunoassays are specifically advocated in therapeutic drug monitoring are indicated in the Table on [p. 107](#).

Thin-layer Chromatography

A. C. Moffat

Thin-layer chromatography (TLC) is one of the most widely used techniques for the separation and identification of drugs. It is equally applicable to drugs in their pure state, to those extracted from pharmaceutical formulations, to illicitly manufactured materials, and to biological samples. It has retained favour as an analytical method primarily because of its simplicity, reliability, low cost, and selectivity of detection through the use of various location procedures.

It is a method of chromatography in which a mobile phase moves by capillary action across a uniform thin layer of finely divided stationary phase (adsorbent) bonded on to a plate. When a mixture of drugs is applied to the plate and developed with the mobile phase, the drugs move across the plate at different rates depending on their solubilities, pKa values, and capability of hydrogen bonding, and so become separated. Although TLC is primarily a separation technique, under controlled conditions it can be used for identification and quantification. TLC has a number of advantages over gas chromatography (GC) and high pressure liquid chromatography (HPLC). The apparatus is cheap and simple and can be used instantly with no warm-up time, a number of samples can be run simultaneously, and there is great flexibility in the choice of the stationary and the mobile phases. It also has the advantage that a substance placed on a plate will remain there, avoiding detection problems associated with non-elution, thermal instability, and masking by the solvent front. TLC has lower sensitivity and resolution than GC and HPLC, although the advent of high performance TLC (HPTLC) has greatly reduced these disadvantages.

MATERIALS

Stationary Phase

A thin layer of the appropriate stationary phase is bonded to a suitable plate made of glass, aluminium foil, or plastic (polyethylene terephthalate). Adherence to the plate is usually assured by mixing a binding agent such as calcium sulphate with the stationary phase. Glass is the most popular plate material, but the others have the advantage that they

can be cut easily to make smaller plates and can be stored conveniently because they are flexible. Most stationary phases are adsorbents (e.g. silica and alumina) and the separation achieved is due to interactions between the drugs and the surface of the stationary phase. Other stationary phases (e.g. cellulose) operate primarily by a partition process between the stationary and mobile phases, although there is often a complex interaction between adsorptive and partition processes. Where the stationary phase is more polar than the mobile phase the system is called a normal-phase system (e.g. silica with non-polar organic solvents), whilst when the mobile phase is the more polar the system is termed a reversed-phase system (e.g. a paraffin-impregnated plate using a water-based mobile phase). Those stationary phases that are widely used are given below.

Silica Gel

Silica gel is hydrated silicic acid and is therefore weakly acidic in nature. It is probably the most popular TLC adsorbent. The adsorbent layer is generally very hard and the plates can therefore withstand being stacked on top of each other and being knocked. When calcium sulphate (gypsum) is used as the binder, the plates are termed silica gel G; the hardest plates use an organic binder. The plates have a uniform distribution of particle size, normally about 20 μm in diameter.

Alumina

Alumina (aluminium oxide) is a weakly basic adsorbent. It has fewer applications than silica and needs to be activated to obtain the best separations.

Kieselguhr

This is naturally occurring amorphous silicic acid from the skeletons of diatoms and hence is often referred to as diatomaceous earth. It has less adsorptive properties than silica.

Magnesium Silicate

This material (Florisil) is usually used only for specialised separations when other adsorbents have failed.

Cellulose

This uses partition processes for separation, and cellulose plates mimic paper chromatography very well. Although plates made from cellulose fibres are still available, those made from 50 μm spherical particles are preferred. Cellulose plates generally run much more slowly than silica plates of the same thickness.

Reversed Phases

Silica plates have been impregnated with materials, such as heavy oils, liquid paraffin, silicone oil, and fats, to form reversed-phase partition TLC systems that use mobile phases containing water. These systems give good separations for a wide range of drugs, but have the disadvantages of being slow running, having poor reproducibility, and giving messy extracts when drugs are eluted from the plates. Plates coated with silica particles which have hydrocarbon chains of various lengths chemically bonded to the hydroxyl groups give stationary phases with high resolving power that can be reproducibly manufactured. The most popular phase is that bonded with a C_{18} (octadecyl) chain of up to 12% w/w loading on the silica. If the loading is higher than 12%, the stationary phase may collapse when the percentage of water in the mobile phase is high (> 10%). Methanol: water or acetonitrile: water can be used as the mobile phase and the chromatographic properties of these TLC systems correlate well with HPLC systems using similar stationary phases.

Ion-exchange Resins

These TLC plates have cation- or anion-exchange resins bonded to their surfaces. The resins are materials such as styrene-divinylbenzene copolymers having either quaternary ammonium or sulphonic acid groupings for ion exchange. They are particularly useful for substances of high molecular weight and for amphoteric materials. Strong acids or alkalis are usually used as mobile phases.

Mobile Phase

The choice of the mobile phase, either a single solvent or a mixture, will depend on the compounds to be separated and the stationary phase to be used. When a stationary phase has been chosen, solvents of increasing elution strength (see [p. 206](#)) can be tried until a particular separation is achieved. Drugs which are strong anions or cations are often best run using ion-pairing agents in the mobile phase.

Solvents should be cheap and easily obtainable in a pure form. They should be stable in air or when mixed with acids or alkalis, capable of being easily removed from the plate after a chromatographic run, non-toxic, and should not react with the substances to be separated.

TECHNIQUE

The technique of TLC involves a number of different stages, namely preparing the plate, applying the sample, running the plate, and locating the spots. These stages are described below.

Preparation of Plates

Prepared TLC plates can be purchased, but they may be prepared easily in the laboratory.

Silica gel Oplates. Mix 30 g of silica gel G (sufficient for five 20 x 20 cm plates) with 60 ml of water, stir well to remove all air bubbles, and quickly apply in a layer 250 μm thick to the plates which have been previously cleaned with acetone to remove grease. Allow the plates to dry in air. Commercial slurry-spreading equipment is available.

When complicated or difficult separations are required it is advisable to use plates 20 cm long, otherwise plates of sizes down to 7.5 x 2.5 cm may be used to save time and materials. The conventional thickness for TLC plates used for analytical work is 250 μm , although plates up to 2 mm thick are used for preparative work.

The chromatographic properties of a TLC plate may be modified by treating the stationary phase with various agents. They may be added by spraying or dipping the plate in an appropriate solution or by adding the modifier at the same time as the plates are being prepared. Simple changes in pH can be effective, e.g. treating silica plates with potassium hydroxide decreases retention and gives more rounded spots for basic drugs. Buffered plates also allow the application of salts or free acids or free bases to the plate. Another example is the use of silver nitrate which can increase the separation of certain compounds, particularly those with carbon-carbon double bonds (this is known as argentation TLC). Other materials that can be useful include ion-pairing agents and fluorescent indicators. Alternatively, an adsorbent stationary phase can be activated by heating at 110° for 1 hour to increase its adsorptive effects and so increase retention. Plates may be scored along their length (by pressing hard with a pencil) to form discrete strips of

adsorbent along which the solvent will run. A 20 x 20 cm plate can give up to 20 such strips, each separated by 2 mm of clear glass. This can improve poor chromatography by allowing the mobile phase to flow up the strip only in straight lines.

Application of Samples

A line is drawn with a pencil parallel to, and 2 cm from, the bottom of the plate. The samples are spotted on to this line, called the origin, starting 2 cm from the side of the plate and at least 1 cm from each other. The sample, normally 1 to 10 μg of material depending on the thickness of the plate, is applied in as small a volume of solvent as possible (usually 1 to 10 μl). It may be applied by a micropipette (commercially available products deliver a known volume with an accuracy of $\pm 2\%$), by a capillary tube drawn out to a fine point, or by a calibrated micro-syringe. Whichever way it is applied, it is vital that the spot is no more than 4 mm in diameter or resolution will be lost. The plate surface must not be cut or gouged by the applicator. The solvent used to apply the spot should be volatile and have low polarity so that the spot does not diffuse too much. The solvent may be applied to the plate in aliquots, and dried off naturally or by use of a hot air blower. It is essential that the spot is dry at the end of application, especially if the solution contains water. Even a small amount of a polar solvent adsorbed on the plate can drastically alter chromatographic properties.

When a large number of samples are to be applied, the use of a template to position the spots accurately is often helpful. Alternatively, automated spotting equipment can be used to apply precise amounts of sample in the position required, either in spots or bands. These devices have the disadvantage of being expensive, difficult to clean, and usually requiring pre-concentration of the sample. Another approach to sample application involves the evaporation of measured volumes of the sample in depressions in a non-wettable polymer film. When dry, the residues are transferred to the plate by pressing the film on to it. It is a very good procedure where the solution is viscous or where it needs to be concentrated.

Some commercial TLC plates have pre-concentration zones. These plates consist of two zones of different adsorbents with a sharply defined boundary, but with the two merging into each other so that the mobile phase does not encounter any resistance in passing from one zone to the other.

One zone is normally kieselguhr, 3 cm long and 150 μm thick, which has comparatively poor adsorptive properties. Thus, any size of spot placed on this layer and run in the mobile phase will become a sharp band before it gets to the analytical silica gel layer. Another form of plate for special applications is one with a pre-concentration zone of octadecyl-silica and an analytical layer of silica. These plates simplify sample application and improve sensitivity, but are very expensive compared with conventional plates. Approximately the same effect can be obtained using conventional plates and running them first in methanol for 0.5 cm. This converts all the spots to thin bands which can then be run in the solvent of choice.

Running the Plates

A saturated developing chamber is normally used. It consists of a glass tank which normally has ground edges at the top to make an airtight seal with the glass lid when coated with soft paraffin. The tank is lined with filter paper on 3 sides and the mobile phase (usually 100 ml for 20x20 cm plates) is added. The tank is then allowed to equilibrate with its vapour for at least 30 minutes. When the vapours in the tank have equilibrated, the TLC plate is placed in a vertical position in the tank so that the application line is above the level of mobile phase. Special racks are available that allow up to 5 plates to be held vertically and developed simultaneously.

Another type of tank is the sandwich unit in which the TLC plate is clamped horizontally between two glass plates separated by gaskets. A wick at one edge of the TLC plate provides the solvent reservoir to develop the plate. The advantage of this system is that it uses less mobile phase, provides a more quickly saturated vapour system, and gives shorter running times.

When either type of tank is used, it is important to flush the tank with nitrogen if the drugs are easily oxidised and to develop in the dark if they are photolabile. These considerations should also be borne in mind when applying the sample and evaporating the solvent from the plate, especially if the drug is also thermolabile.

It is conventional to develop 20-cm plates for a distance of 10 or 15 cm although this may involve waiting for up to 2 hours for a viscous mobile phase on a cold day. However, the development time can be considerably reduced if the plates are run for only 5 cm, since there is an exponential increase in development time with increasing development

distance. For example, a 5-cm run using methanol on silica takes 15 minutes, whereas it takes 45 minutes for a 10-cm run. The other advantages of shorter running distances are an increase in sensitivity (because spots do not diffuse so far) and a saving on materials. The major disadvantage is that resolution is lost, e.g. about a 20% decrease in going from a 10-cm to a 5-cm development distance.

Once the plate has been developed for the predetermined distance, it is removed from the tank and the position of the solvent front quickly marked before any solvent evaporates. The solvent can then be allowed to evaporate naturally or removed with a hot air blower.

CONTINUOUS AND MULTIPLE DEVELOPMENT

Although it is possible to separate completely up to 10 compounds using a 10-cm run, a single run will not always separate all the compounds of interest. In these cases, continuous development may be used by running the mobile phase up the plate and removing it from the top by means of a wick, or by evaporating it using an infra-red lamp.

Although the above procedure is relatively simple, it is better to use a form of multiple development. The plate is run in one mobile phase, dried, and then run again in the same direction using either the same mobile phase or a more polar one, or one with a different pH. This procedure may be repeated a number of times to achieve the desired separations. It is especially useful when separating compounds of very different polarities.

Two-dimensional TLC can be useful when particular separations are needed. The plate is run in one direction with the first mobile phase, dried, turned through 90°, and run again using a different mobile phase. This method is better than linear development since all the plate is used for separating the components of a sample. However, only one sample can be separated on each plate.

Location Procedures

As most organic compounds are colourless, they must be made visible, preferably by a nondestructive technique. Many compounds can be located by examining a plate containing a fluorescent indicator under short wavelength (254 nm) ultraviolet light; absorbing compounds are seen as dark spots on a green background. If long wavelength (350 nm) ultraviolet light is also used, drugs which naturally fluoresce will be seen, e.g. quinine gives a bright blue spot. Any spots visualised with these procedures

should be ringed in pencil. Some drugs will not absorb ultraviolet light because they are in the wrong ionic form on the plate due to the pH of the buffered plate or solvent system used. For example, barbiturates are not visible if the plate is acidic, but are readily seen when ammonia fumes are blown over the plate. Similarly, some bases may be seen more easily if hydrochloric acid fumes are used to change the pH of the plate.

Further non-destructive tests can be performed, such as putting the plate in a tank of iodine vapour to see if brown spots appear. Another example is the use of photographic film for determining the position of radioactive drugs and metabolites in metabolic studies. In addition, pH indicators can be sprayed on the plate, e.g. bromothymol blue which is yellow in an acidic medium and blue in an alkaline medium. Reagent sprays should be applied to the plate as fine aerosols using a hand pump, compressed air line, or propellant cartridge. The spray should be moved backwards and forwards quickly to cover the whole plate but not applying so much that the plate looks wet.

Another very useful general, but destructive, test is to pour *sulphuric acid* on the plate and gently warm it. Organic materials char to produce black or brown spots. Alternatively, the plate can be heated in an atmosphere of ammonium bicarbonate when many compounds give fluorescent derivatives, the sensitivity of detection of which is about ten times that of the sulphuric acid treatment.

Spray reagents may be used either as general locating agents for the visualisation of any drug present (e.g. iodine in methanol) or to pick out one specific class of drug (e.g. *FPN reagent* for pheno-thiazines). In between these types of reagents are those that can be used as functional group tests (e.g. fluorescamine for primary amines) and others that react with general groups of compounds (e.g. *Dragendorff spray* for alkaloids). In addition, there are reagents such as *Marquis reagent* and *Mandolin's reagent* that give a wide range of colours and can be very useful in identification procedures. In many cases, spray reagents can be sprayed on top of each other on the plate, provided that the drugs are not destroyed or the pH of the plate is not altered too much by the previous spray.

Suitable locating reagents are listed under the TLC systems described at the end of this chapter, and details of their composition are given in the Reagent Appendix. The reagents described under Colour Tests (p. 128) may also be used as TLC location reagents.

STORAGE OF CHROMATOGRAMS

Aluminium and plastic TLC plates are flexible and can easily be mounted with glue or adhesive tape in case books. Glass plates can be stored flat, but quickly become a storage problem in a busy laboratory. It is therefore better to trace the chromatogram on paper, indicating the colours of the spots. Alternatively, the TLC plate can be photographed (preferably with a camera that gives instant prints) or photocopied. In either case, colour reproductions are much more useful than black and white pictures. The actual layer on a glass plate can be preserved and removed by spraying with a solution of a polymer, e.g. polyvinyl propionate, which sets to a clear pliable plastic film. This film can be stripped off the glass plate under water with the adhering TLC layer, dried, and mounted as for a plastic TLC plate.

R_f VALUES

The basic chromatographic measurement of a substance in TLC is the R_f value, defined as

$$R_f = \frac{\text{Distance the substance travels from the origin}}{\text{Distance the solvent front travels from the origin}}$$

This value varies from 0 to 1. However, it is more usual to quote R_f × 100 values to avoid the use of decimals. These R_f × 100 values are sometimes referred to as hR_f values, but for simplicity they are subsequently referred to in this chapter and elsewhere as R_f values. The distance travelled by the substance is measured from the centre of the spot, which is easily determined if the spot is round, but with tailing spots it should be measured from the middle of the most dense area.

R_f values are affected by a number of factors and therefore an authentic sample of the suspected drug should be run at the same time on the same plate as the test sample whenever possible. If this is not possible, a reference compound can be run at the same time and the relative R_f value quoted as the ratio of the distances moved by the test substance and the stated reference compound (R_r or RR_f value). By far the best approach is to run simultaneously a number of reference compounds whose R_f values are accurately known and then correct the R_f value of the test substance (R_{fc} value).

Factors Affecting the Reproducibility of R_f Values

Since R_f values are often used in identification procedures, it is important to recognise those factors

affecting reproducibility. The most important factors are given below.

Stationary Phase

The quality of the adsorbent and binder, presence of impurities, and uniformity of thickness must be carefully maintained or batch to batch variations will occur. If the plates are to be activated, the procedure should be the same on each occasion. Plates should be stored over silica gel in a desiccator before use and the sample should be applied quickly so that the water vapour in the atmosphere is not adsorbed by the plate. Because of the difficulties associated with activation procedures it is far better to use plates stored at room temperature and not to activate them. The spots must be at least 2 cm from the side of the plate and the solvent used for applying the sample must be completely removed before the plate is run.

Mobile Phase

This should be prepared accurately from pure solvents, and made freshly for each run if one of the solvents is very volatile or hygroscopic, e.g. acetone.

Developing Tank

It is important that saturated conditions are attained for running TLC plates. This is best accomplished by using small tanks with filter paper liners and sufficient solvent, and by leaving the tank to equilibrate for at least 30 minutes before running the plates. A well-fitting lid is essential.

Temperature

Although precise control of temperature is not necessary, the tank should be kept away from draughts, sources of heat, direct sunlight, etc. As the temperature is increased, volatile solvents evaporate more quickly, solvents run faster, and R_f values generally decrease slightly.

Development Distance

There are no great changes in corrected R_f values with changes in development distance provided that the system is kept saturated. If it is not, there is an apparent increase in R_f value with increase in running distance due to the increased evaporation of the solvent from the upper parts of the plate.

Mass of Sample

Increasing the mass of sample on the plate will often increase the R_f of a drug, especially if it normally tails in the system. For example, using a silica gel plate and chloroform:acetone (4:1) as mobile phase,

5 µg of benzoic acid has an R_f of 26, but 20 µg has an R_f of 34. However, if a plate is grossly overloaded, this too will give a tailing spot and will have the effect of apparently decreasing the R_f value. The two situations are normally easy to distinguish by the intensity of the spot.

In general, R_f values are less reproducible in the middle of a chromatogram than at high or low R_f values. However, these differences in reproducibility are not very dramatic and for practical purposes reproducibility can be regarded as independent of the magnitude of the R_f values.

From the above, it is obvious that the standard deviation of measurements of R_f values can be considerable even if all due care is taken. The best way to increase reproducibility is to run an authentic sample at the same time, or to use corrected R_f values. This involves running, at the same time as the test sample, a number of reference compounds (usually 4), the R_f values of which are accurately known. The R_f value of the test substance can then be corrected by a graphical method or by linear regression analysis. Thus, a 6-point correction graph can be drawn by plotting the experimentally determined R_f values of the four reference compounds against their accurately known values, together with the 0,0 (origin) and 100,100 (solvent front) points. The requirements for the reference compounds are that they produce round and distinct spots, and are equally spaced across the chromatographic range. This procedure can reduce the inter-laboratory standard deviation from about 6 R_f units to about 3 R_f units.

SPECIAL TECHNIQUES

Preparative TLC

One of the major uses of TLC is as a separative or purification technique. Preparative TLC is very useful to isolate components in a mixture, either for further analytical studies or to obtain pure materials for use as standards. An analytical TLC plate is normally 100 to 250 µm thick, whilst preparative plates are from 0.5 to 2 mm thick. They can accept from 10 to 100 mg of material depending on the number of components and their chemical nature. As a general rule, the amount that can be applied to a TLC plate without overloading it (the capacity) increases as the square root of the thickness of the adsorbent layer. It is generally better to apply the sample as a band rather than a spot, so that the maximum amount of sample can be chromatographed at the same time.

It is often easier to elute drugs from silica than from either cellulose or alumina, and only bonded stationary phases should be used in reversed-phase systems or else the organic stationary phase will also be eluted. These points should be considered when choosing the stationary phase.

After the plate has been run, non-destructive locating procedures such as the use of ultraviolet light or iodine vapour should be used. If a reagent spray must be used, it should be sprayed only on a small strip of the chromatogram to allow the maximum use of the rest of the material, although not all spray reagents have irreversible effects. For example, the complex formed when basic drugs are sprayed with potassium iodoplatinate solution can be decomposed by aqueous acid containing 10% w/v sodium sulphite. Once the area containing the drug of interest has been located, it should be scraped off and eluted in a Pasteur pipette or in a funnel, using glass wool to trap the stationary phase. Alternatively, elution can be accomplished in a test-tube followed by centrifugation to separate the phases. A solvent of high eluting power, such as methanol, should be used. Highly adsorbed substances (those with low R_f values) may take several minutes to be eluted from the stationary phase. Often it is better to wet the stationary phase before extracting with the organic solvent, or better still elute with aqueous acid or alkali and then extract the aqueous phase with an organic solvent after changing the pH. It is always useful to treat an area of equal size, scraped from another part of the plate where no drug is present, to act as a control.

Using one of the above procedures, a recovery of 50 to 80% is relatively easy, although devices are available which elute directly from the plate and which claim better than 99% efficiency. These devices fit directly over the spot, after scraping away a ring of stationary phase, and solvent is pumped in from one side of the device and collected at the other side.

Thin-layer Rods

The latroscan TH-10 analyser combines TLC with a flame ionisation detector to give the benefits of simple chromatography with a universal detector. It uses rods which are about 150mm long and 0.9 mm in diameter with a coating of silica 75 µm thick. The sample is applied near one end of the rod, and developed in a conventional TLC tank. The rod is then dried and scanned using a flame ionisation detector (which takes only 20 seconds).

The sensitivity can be as good as 200 ng, but 1 to 20 µg is the optimum working range. Although developed primarily for quantitative work the method has a coefficient of variation of 10% for quantification. It is also difficult to remove the background signal when using a mobile phase of low volatility and, if the rod is heated enough to remove the solvent, volatile drugs can be lost. These features, linked with the destructive nature of the detector, limit the usefulness of the method.

High Performance Thin-layer Chromatography

The availability of new materials, methods, and instrumentation over the last 10 years has so greatly altered TLC, that the new form is now called high performance TLC (HPTLC). The HPTLC plates are far superior to the conventional type, having much smaller particles (2 to 7 µm) as well as a very narrow particle size distribution. This makes HPTLC faster, more reproducible, more sensitive, and more accurate for quantitative work. Its growth in drug applications has been greatly speeded by the use of automated sample application devices and accurate densitometers. A comparison of HPTLC and TLC is given below.

<i>Typical conditions</i>	<i>TLC</i>	<i>HPTLC</i>
Plate dimensions (cm)	20 × 20	10 × 10
Particle size (silica) (µm)	about 20	about 5
Layer thickness (analytical) (µm)	100–250	150–200
Sample volume (µl)	1–10	<0.1
Spot diameter before running (mm)	<4	<1.5
Spot diameter after running (mm)	5–10	2–5
Running distance (cm)	10–15	3–6
Running time (min)	30–120	5–15
Number of samples per plate	10–15	30–40
Detection limit (absorption)* (ng)	10–100	0.5–5
Detection limit (fluorescence)* (ng)	0.1–1	0.01–0.1
Reproducibility of R _f values	about 3%	about 1%
Reproducibility of quantification	about 5%	2–3%

The main disadvantages of HPTLC are the inability to use another identification technique after eluting a separated sample (since so little sample is used) and the interference of co-extracted material in tissue extracts.

SELECTION OF TLC SYSTEMS

The selection of the best system for a particular application will depend on the use to which it is to be put. For quantification it is most important that both the drug to be measured and the internal standard produce round spots of reproducible magnitude and that they are adequately separated.

However, for identification purposes, the R_f values must be as reproducible as possible and there must be as much separation between drugs as possible. If a drug is to be separated from unwanted materials, a series of solvents of increasing eluting strength (see p. 206) can be tried until the necessary separation is achieved. When a large number of compounds are to be separated, e.g. for a screening or identification procedure, there are three main features of a TLC system to be considered. Firstly, the system should have a good distribution of R_f values across the plate for the compounds of interest to ensure the maximum probability of separation. Secondly, the R_f values should be as reproducible as possible. Lastly, the correlation of chromatographic properties between systems should be low, so that extra information is obtained when more than one system is used for identification purposes. Features such as sensitivity and speed of running are generally similar whichever TLC system is chosen.

Discriminating Power

To compare the ability of TLC systems to achieve a particular separation, a mathematical method of comparison is needed. A simple method is to use discriminating power measurements. Discriminating power is defined as the probability that two drugs selected at random would be separated by the TLC system. It has a number of advantages over other methods of evaluation in that it is easy to calculate, it can account for the different reproducibilities of systems, it can easily be used for combinations of systems, and it has a simple range of values, i.e. 0 to 1.

Discriminating power is calculated by running the drugs of interest in the TLC system to be evaluated and comparing the measured R_f values for each drug in turn with R_f values for each of all the other drugs. If the R_f values are within a predetermined error factor they are considered to be undiscriminated (or matched) and the total number of matches from all the drugs is designated *M*. The total number of possible matches is

$$\frac{N(N-1)}{2}$$

(where *N*=total number of drugs) and therefore the probability of two drugs selected at random being matched is

$$\frac{2M}{N(N-1)}$$

Hence,

$$\text{discriminating power} = 1 - \frac{2M}{N(N-1)}$$

It should be noted that the concept of discriminating power can be applied to GC and HPLC as well as TLC.

QUANTIFICATION

Recent advances in densitometers and data processing devices have brought quantitative TLC into the same accuracy range (2-5% coefficient of variation) as GC and HPLC. Sample application is still a very critical part of quantitative TLC, although calibrated micro-pipettes, micro-syringes, and the use of internal standards, have solved most of the problems. Densitometers can work in transmittance, fluorescence quenching, or reflectance modes for measuring absorbance, and can also measure fluorescence, which is more sensitive for those drugs that do fluoresce. The plates can be read with a high degree of resolution (12 μm) and spots can be scanned many times in order to improve the signal-to-noise ratio by averaging the signals.

When quantitative measurements are made using internal standards, the calibration curves of concentration versus peak-height ratios or peak-area ratios are normally non-linear. Whilst this is a disadvantage, a data processor linked to a densitometer will ensure that accuracy is not lost. The ability of HPTLC to run up to 40 samples simultaneously can make the use of densitometry a viable proposition for therapeutic drug monitoring programmes or for pharmacokinetic studies where large numbers of similar samples are being analysed together.

Although less popular, the use of radioactivity scanners for TLC plates still has a useful role to play in the analysis of radioactive drugs and metabolites. Alternatively, the spot can be scraped off and counted in a scintillation counter.

SYSTEMS FOR THIN-LAYER CHROMATOGRAPHY

The TLC systems given below are general screening methods for nitrogenous bases (Systems TA, TB, and TC) and for acids and neutral compounds (Systems TD, TE, and TF) together with 17 other systems for specific groups of drugs. The drugs are divided into chemical or pharmacological groups but some other drugs are included with certain groups if they are chemically similar and would be extracted with that group.

There may not be one best system for a particular separation and a number of systems can be applied from those suggested. However, each of the systems described has been selected because it gives a good spread of R_f values, has high reproducibility, and has low correlation with the other systems selected for that group of drugs. These systems have proved useful for a large number of groups of drugs over the years and are robust and dependable. At least three systems are given for each group, where possible. The R_f values of the reference compounds suggested for the six general screening systems have been derived using 5 to 10 μg of the substance.

Fluorescent plates should always be used and the absorption or fluorescence of the drug under ultraviolet light (both 254 and 350 nm) should be used as a location procedure. The suggested locating agents include general ones to visualise any drug that might be present as well as more specific ones to pick out individual classes of drugs.

NOTE. In the tables of R_f values, a dash indicates that no value is available for the compound.

BASIC NITROGENOUS DRUGS, GENERAL SCREEN

A. H. Stead *et al.*, *Analyst, Lond.*, 1982, 707, 1106-1168.

System TA

PLATES. Silica gel G, 250 μm thick, dipped in, or sprayed with, 0.1M potassium hydroxide in methanol, and dried.

MOBILE PHASE. *Methanol: strong ammonia solution* (100:1.5).

REFERENCE COMPOUNDS. Diazepam R_f 75, chlorprothixene R_f 56, codeine R_f 33, atropine R_f 18.

System TB

PLATES. This system uses the same plates as System TA with which it may be used because of the low correlation of R_f values.

MOBILE PHASE. Cyclohexane: toluene: diethylamine (75:15:10).

REFERENCE COMPOUNDS. Dipipanone R_f 66, pethidine R_f 37, desipramine R_f 20, codeine R_f 06.

System TC

PLATES. This system uses the same plates as Systems TA and TB with which it may be used because of the low correlation of R_f values.

MOBILE PHASE. Chloroform: methanol (90:10).

REFERENCE COMPOUNDS. Meclozine R_f 79, caffeine R_f 58, dipipanone R_f 33, desipramine R_f 11.

LOCATION REAGENTS. For Systems TA, TB, and TC. *Ninhydrin spray.* Spray the plate with the reagent and then heat in an oven at 100° for 5 minutes. Violet or pink spots are given by primary amines and yellow colours by secondary amines.

FPN reagent. Red or brown-red spots are given by phenothiazines and blue spots by dibenzazepines. This reagent may be used to overspray a plate which has been previously sprayed with *ninhydrin spray*. *Dragendorff spray.* Yellow, orange, red-orange, or brown-orange spots are given by tertiary alkaloids. This reagent may be used to overspray a plate which has been previously sprayed with *ninhydrin spray* and *FPN reagent*.

Acidified iodoplatinate solution. Violet, blue-violet, grey-violet, or brown-violet spots on a pink background are given by tertiary amines and quaternary ammonium compounds. Primary and secondary amines give dirtier colours. This solution may be used to overspray a plate which has been previously sprayed with *ninhydrin spray*, *FPN reagent*, and *Dragendorff spray*.

Mandolin's reagent. This reagent is preferably poured on to the plate because of the danger of spraying concentrated acid. Many different colours are given with a variety of drugs (see under Colour Tests, p.137).

Marquis reagent. This reagent is preferably poured on to the plate because of the danger of spraying concentrated acid. Black or violet spots are given by alkaloids related to morphine. Many different colours are given with a variety of drugs (see under Colour Tests, p. 139).

Acidified potassium permanganate solution. Yellow-brown spots on a violet background are given by drugs with unsaturated aliphatic bonds.

Rf VALUES. Rf values for drugs in these systems will be found in drug monographs and in the indexes to Analytical Data in Part 3; they are also included in the systems for specific groups of drugs which follow.

ACIDIC AND NEUTRAL DRUGS, GENERAL SCREEN

A. H. Stead *et al.*, *Analyst, Lond.*, 1982, 707, 1106-1168.

System TD

PLATES. Silica gel G, 250 µm thick.

MOBILE PHASE. Chloroform: acetone (4:1).

REFERENCE COMPOUNDS. Methohexitone Rf 73, quinalbarbitone Rf 55, clonazepam Rf 35,

paracetamol Rf 15.

System TE

PLATES. This system uses the same plates as System TD with which it may be used because of the low correlation of Rf values.

MOBILE PHASE. Ethyl acetate: methanol: *strong ammonia solution* (85:10:5).

REFERENCE COMPOUNDS. Prazepam Rf 81, temazepam Rf 63, hydrochlorothiazide Rf 34, sulphadimidine Rf 13.

System TF

PLATES. This system uses the same plates as Systems TD and TE with which it may be used because of the low correlation of Rf values.

MOBILE PHASE. Ethyl acetate.

REFERENCE COMPOUNDS. Quinalbarbitone Rf 68, salicylamide Rf 55, phenacetin Rf 38, sulphathiazole Rf 20.

LOCATION REAGENTS. For Systems TD, TE, and TF.

For acidic drugs:

Van Urk reagent. Spray the plate with the reagent and then heat in an oven at 100° for 5 minutes. Yellow spots are given by sulphonamides and by meprobamate, blue spots are given by ergot alkaloids, and pink or violet spots are given by some other compounds, e.g. phenazone.

Ferric chloride solution. Blue or violet spots are given by phenols. This solution may be used to overspray a plate which has been previously sprayed with *Van Urk reagent*.

Mercurous nitrate spray. Barbiturates give dark spots which fade slowly; with some dilute solutions the spots fade rapidly.

Acidified potassium permanganate solution. Yellow-brown spots on a violet background are given by drugs with unsaturated aliphatic bonds, e.g. quinalbarbitone. This solution may be used to overspray a plate which has been previously sprayed with *mercurous nitrate spray*.

For neutral drugs:

Furfuraldehyde reagent. Violet to blue-black spots are given by some neutral compounds, e.g. carbamates.

Acidified iodoplatinate solution. This solution may be used to overspray a plate which has been previously sprayed with *furfuraldehyde reagent*. Acidified potassium permanganate solution.

Rf VALUES. Rf values for drugs in these systems will be found in drug monographs and in the indexes to Analytical Data in Part 3; they are also included in the systems for specific groups of drugs which follow.

AMPHETAMINES, OTHER STIMULANTS, AND ANORECTICS

Systems TA, TB, or TC, previously described, may be used together with the associated location reagents.

BARBITURATES

Systems TD or TE, previously described, may be used or System TH, below, which gives the best separations.

System TH

PLATES. Silica gel G, 250 µm thick.

MOBILE PHASE. Isopropyl alcohol: chloroform: strong ammonia solution (90:90:20).

LOCATION REAGENTS. For Systems TD, TE, and TH. *Mercuric chloride-diphenylcarbazone reagent*.

White spots on a violet background are given in neutral systems, and violet spots on a pink background are given if the plate is alkaline. *Acidified potassium permanganate solution*. Yellow-brown spots on a violet background are

brown spots on a violet background are given by drugs with unsaturated aliphatic bonds.

Zwicker's reagent. Pink spots are given by 5,5-disubstituted barbiturates, green spots are given by thiobarbiturates, and faint pink spots are given by bromobarbiturates and by 1,5,5-trisubstituted barbiturates. The test is not very sensitive. *Fluorescein solution*. Spray the plates with a 10% solution of sodium hydroxide and heat at 100° in an oven for 5 minutes before applying the reagent. Pink spots are given by bromobarbiturates.

Mercurous nitrate spray. Barbiturates give dark spots which fade slowly; with some dilute solutions the spots fade rapidly.

CANNABINOIDS

These systems may be used for extracts of both cannabis and cannabis resin.

System TI

PLATES. Silica gel G, 250 μm thick, dipped in, or sprayed with, a 10% solution of silver nitrate, and dried.

MOBILE PHASE. Toluene, using unsaturated (open tank) conditions.

System TJ

PLATES. Silica gel G, 250 μm thick, sprayed with diethylamine immediately before use.

MOBILE PHASE. Xylene: hexane: diethylamine (25:10:1).

LOCATION REAGENTS. For Systems TI and TJ.

Fast blue B solution. Cannabidiol gives an orange colour, cannabinal gives a violet colour, and Δ^9 -tetrahydrocannabinol gives a red colour. The colours may be intensified by overspraying with M sodium hydroxide or by exposing the plate to ammonia fumes.

Duquenois reagent. After spraying with the reagent, overspray the plate with *hydrochloric acid*. Blue to violet colours are given by cannabinoids.

CARDIAC GLYCOSIDES

System TK

E. J. Johnston and A. L. Jacobs, *J. pharm. Sci.*, 1966, 55, 531-532.

PLATES. Silica gel G, 250 μm thick, activated at 120° for 45 minutes. They should be stored in a desiccator.

MOBILE PHASE. Benzene: ethanol (7:3).

LOCATION REAGENTS

Perchloric acid solution. This gives spots which fluoresce under ultraviolet light (350 nm); a charring effect is produced after the sprayed plate has been heated in an oven at 100° for a few minutes.

p-Anisaldehyde reagent. After spraying with the reagent, heat in an oven at 100° for a few minutes. Blue spots are given by cardiac glycosides except for ouabain which gives a yellow spot.

ERGOT ALKALOIDS

Systems TL and TM

R. E. Ardrey and A. C. Moffat, *J. forens. Sci. Soc.*, 1979, 79, 253-282.

These systems can be run in a single tank as they use the same mobile phase and have low correlation of Rf values.

System TL

PLATES. Silica gel G, 250 μm thick, dipped in, or sprayed with, 0.1M potassium hydroxide in methanol, and dried.

MOBILE PHASE. Acetone.

REFERENCE COMPOUNDS. Meclozine Rf 70, mepivacaine Rf 48, procaine Rf 30, amitriptyline Rf 15.

System TM

PLATES. Aluminium oxide, 250 μm thick.

MOBILE PHASE. Acetone.

REFERENCE COMPOUNDS. Lysergide Rf 70, ergotamine Rf 48, ergometrine Rf 26.

LOCATION REAGENTS. For Systems TL and TM. *Naphthoquinone sulphonate solution*. Spray the plate with the reagent, then spray with a 10% v/v solution of *hydrochloric acid* and heat at 110° for 20 minutes.

Red-violet spots on a light pink background are given by ergot alkaloids.

Nitroso-naphthol solution. Spray the plate with the reagent, then spray with a 10% v/v solution of *hydrochloric acid* and heat at 110° for 20 minutes.

Blue-black spots on a yellow background are given by ergot alkaloids.

Van Urk reagent. After spraying the plate, heat in an oven at 100° for 5 minutes. Blue spots are given by ergot alkaloids.

STEROIDS

Systems TP, TQ, TR, and TS

Pharmaceutical Codex, 11th Edn, London, Pharmaceutical Press, 1979, p. 940.

System TP

PLATES. Silica gel G, 250 μ m thick.

MOBILE PHASE. Methylene chloride: ether: methanol: water (77:15:8:1.2).

System TQ

PLATES. Silica gel G, 250 μ m thick.

MOBILE PHASE. Dichloroethane: methanol: water (95:5:0.2).

System TR

PLATES. Kieselguhr, 250 μ m thick, impregnated with a mixture of acetone: formamide (9:1).

MOBILE PHASE. Toluene: chloroform (3:1).

System TS

PLATES. Kieselguhr, 250 μ m thick, impregnated with a mixture of acetone: propylene glycol (9:1).

MOBILE PHASE. Cyclohexane: toluene (1:1).

LOCATION REAGENTS. For Systems TP, TQ, TR, and TS.

DPST solution.

Sulphuric acid-ethanol reagent. Spray the plate and then heat at 105° for 10 minutes.

p-Toluenesulphonic acid solution. Heat the plate at 120° for 15 minutes, cool, spray with the reagent, heat again at 120° for 10 minutes, and respray.

Gas Chromatography

H. Leach and J. D. Ramsey

Gas chromatography, like other forms of chromatography, is a method of separating mixtures of substances of analytical interest either from each other or from an extraction residue. The equipment may be simple or complex, but the principle is a simple one and is analogous to other forms of chromatography.

The separation is performed on a column containing the stationary phase, either solid or liquid, which is maintained at a defined temperature in an oven and has a constant flow of carrier gas (mobile phase). When a mixture of substances is injected at the inlet, each component is swept towards the detector and is partitioned between the stationary phase and the gas phase. Molecules with the greatest affinity for the stationary phase spend more time in that phase and consequently take longer to reach the detector. The detector produces a signal dependent on the mass of substance passing through it and this signal is processed and fed to a chart recorder and perhaps to an integrator. Each substance passing through the column will have a characteristic *retention time* which is defined as the time (minutes) from injection to peak maximum at the detector.

Most gas chromatography (other than capillary chromatography, see page 181) is performed on packed columns of glass [$\frac{1}{4}$ in (6.4 mm) outside diameter and 4 mm internal diameter] or stainless steel [$\frac{1}{8}$ in (3.2 mm) outside diameter and 2 mm internal diameter], 0.5 to 4 metres long. Glass is more inert than stainless steel, and has the advantage that the packing is visible.

Gas chromatography may be divided into gas-solid chromatography (mainly adsorptive processes) and gas-liquid chromatography (mainly partition) depending on whether the stationary phase is a solid or a liquid at its operating temperature. If the stationary phase is a liquid it must be coated on a support for packed column chromatography. For capillary column chromatography, the stationary phase may be coated directly on to the walls of the column, or on to a support which is bonded to the glass walls.

GAS-SOLID CHROMATOGRAPHY

Stationary Phases

In gas-solid chromatography, the stationary phase is an active solid. These solids may be inorganic materials, e.g. synthetic zeolite molecular sieve, carbon molecular sieve, silica gel, or graphitised carbon, or they may be organic polymers. They are generally used for the separation of low molecular weight materials, i.e. gases and liquids.

Molecular Sieve (4A, 5A, 13X) gives good general separation of inorganic gases. Carbon dioxide is irreversibly adsorbed below 160°. Oxygen and nitrogen are well separated. Carbon monoxide in blood is commonly measured using molecular sieve 5A. Carbosieve is a granular carbon molecular sieve useful for the separation of C_1 to C_3 hydrocarbons.

Silica Gel gives good separation of inorganic gases. Porasil is porous silica with a surface area between 1.5 and 500 m²/g and may be used as conventional silica gel or may be coated. Carbon dioxide, carbon monoxide, hydrogen, and nitrogen are all separated. Oxygen and nitrogen are not resolved.

Molecular sieve and silica gel columns can be used in parallel for the analysis of respiratory gases where resolution of oxygen, nitrogen, and carbon dioxide is of importance.

Chromosorb and *Porapak* series are divinylbenzene cross-linked polystyrene copolymers. Different members of the series vary in surface area and average pore diameter. Separations range from free fatty acids to free amines. Alcohols from methanol to pentanol can be separated on Porapak Q or Chromosorb 102. The maximum operating temperature is about 250°.

Tenax-GC is a porous polymer of 2,6-diphenyl-*p*-phenylene oxide. This material is used both as a chromatographic phase and as a trap for volatile substances prior to analysis.

Carbopak B and *C* are graphitised carbon black, having surface areas of 12 and 100 m²/g, respectively. They are usually modified with a light coating of a polar stationary phase. Difficult separations of the C_1 to C_{10} hydrocarbons can be achieved

rapidly. Carbowax 20M has been used to resolve substances abused by 'glue-sniffers'. Carbowax 1500 is the phase of choice for the analysis of ethanol in blood. Carbowax C with 0.8% tetrahydroxyethylenediamine (THEED) is useful for the determination of ethylene glycol in blood. They give approximately the same order of elution of compounds as the Porapak and Chromosorb series, but generally with better resolution.

GAS-LIQUID CHROMATOGRAPHY

In gas-liquid chromatography, the stationary (liquid) phase is coated on a support material.

Support Materials

The behaviour of the column is largely dependent on the stationary phase but the support material can also play a very important role, particularly when a low concentration of liquid phase is used. A good support material should have a very large surface area and a uniform particle size, free from fines and sufficiently robust so that it does not break up into powder with normal handling. It should be chemically inert, without adsorptive effects, and, when coated with stationary phase, should pack easily and uniformly into the column.

The raw material for the most commonly used supports is diatomaceous earth, calcined, usually with a flux, then crushed and graded into a number of particle sizes. The sizes in general use are 60-80, 80-100, and 100-120 mesh.

Chromosorb P is a red diatomaceous earth which has the advantage of resistance to the formation of fines, but it is now rarely used. It is a relatively dense preparation with a packed density of 0.5 g/cm³, and a surface area of 4 m²/g. The 'P' denotes the pink colour.

Chromosorb W is a diatomaceous earth calcined with the addition of sodium carbonate. It is less dense than Chromosorb P, with a packed density of approximately 0.3 g/cm³, and is softer with a greater tendency to produce fines. The surface area is about 1 m²/g. *Celite 545* is similar to Chromosorb W.

Chromosorb G is a calcined diatomaceous earth with a density similar to that of Chromosorb P but the surface area is much less, about 0.5 m²/g, and it is the least reactive of the Chromosorbs. The high resistance to mechanical damage together with the density and inertness make it very suitable for low-loaded columns. The amount of stationary phase

should not exceed 5% w/w, which is equivalent to 12.5% w/w on other supports.

DEACTIVATION

Various deactivation procedures are applied to support materials. These include acid- or base-washing to remove impurities and fine particles, and treatment with a silanising agent which reacts with surface hydroxyl groups and reduces adsorptive effects. A very light coating of a polar stationary phase may also be used to increase deactivation. Commercial support materials which have been treated by these procedures are available and are usually designated by a suffix to the name, e.g. AW (acid washed) and AW HMDS (acid washed, hexamethyldisilazane treated). Deactivated supports are nearly always to be preferred, but it should be noted that the deactivation procedure may impose an upper temperature limit and may modify the polarity of the stationary phase.

Support materials which have the liquid phase chemically bonded to them are available. These offer decreased bleed rates of stationary phase, an advantage when operating a temperature programme or when using a mass spectrometer as the detector.

Choice of Stationary Phases

Over seven hundred substances have been used as stationary phases. The choice of stationary phase for a particular separation is often a matter of serendipity, depending on a combination of experience, prejudice, intuition, and the desire to use an existing system if it will do the job.

It has been shown that the retention behaviour of benzene, butanol, pentan-2-one, nitropropane, and pyridine can be used to classify stationary phases in terms of their polarity (W.O. McReynolds, *J. chromatogr. Sci.*, 1970, 8, 685-691). The retention indices of each of these five reference compounds are measured, first on the stationary phase being tested and then on a standard phase (squalane). The differences in retention index between the two phases (ΔI) for the five reference compounds are added together to give a constant which is a measure of the polarity of the stationary phase. This constant is known as the *McReynolds Constant* and can be used to compare the ability of stationary phases to separate different classes of compounds (see below). However, this constant gives no information about peak shape, temperature limits, or the suitability for use in capillary columns.

McReynolds Constants of some liquid phases

<i>Liquid phase (maximum temperature)</i>	<i>McReynolds Constant (increasing order of polarity)</i>
Squalane (150°) (reference phase)	0
Apolane-87 (260°)	71
Apiezon L (300°)	143
SE-30 (300°)	217
OV-1 (350°)	222
OV-101 (350°)	229
Apiezon L/KOH (225°)	301
OV-7 (350°)	592
OV-17 (350°)	886
Versamid 900 (275°)	986
Poly A103 (275°)	1072
Carbowax 20M/KOH (225°)	1296
OV-225 (250°)	1813
CHDMS (cyclohexanedimethyl succinate) (250°)	2017
Carbowax 20M (225°)	2308

A system for assessing the effectiveness of chromatographic systems by calculating the discriminating power has been described (A. C. Moffat *et al.*, *J. Chromat.*, 1974, 90, 1-7). Using this method, a number of stationary phases commonly used in toxicology have been examined (A. C. Moffat *et al.*, *J. Chromat.*, 1974, 90, 19-33). It was shown that SE-30 columns eluted all the drugs studied and that for screening purposes a single column, either SE-30 (or its more modern equivalents) or OV-17, was sufficient for the identification of drugs. There is little to be gained by using a series of columns of increasing polarity, and high polarity columns are of marginal utility since many drugs which elute from low polarity stationary phases do not elute from high polarity phases. Thus the use of a multiplicity of columns gives little additional evidence of identification and in most cases is counter-productive.

The choice of phases for capillary columns is less than for packed columns, particularly for silica columns. However, the high efficiency available with a capillary column will often more than compensate for the lack of selectivity obtainable with a different phase.

NON-POLAR PHASES

Apiezon L is a hydrocarbon grease which is used for the separation of barbiturates. It has the advantage over the silicone phases that it is stable when coated with alkali to reduce the tailing of strongly basic compounds. The amphetamines may be separated on a column of 10% Apiezon L with 2% potassium hydroxide.

SE-30, *OV-1*, and *OV-101* are dimethyl silicone polymers which may be regarded as equivalent as

far as retention data are concerned. SE-30 is preferred by some workers as a stationary phase for capillary columns although it has a lower maximum operating temperature. OV-1 is preferred for packed columns and has a maximum operating temperature of 350°. Separations on these phases are largely on the basis of molecular weight. A new separation should be attempted first on one of these phases, and only if it is unsuccessful or if a poor peak shape results should a more polar phase be tried. In general, non-polar compounds chromatograph best on non-polar phases and polar compounds on polar phases.

Apolane-87 (24,24-diethyl-19,29-dioctadecylheptatetracontane) is a high temperature non-chiral hydrocarbon phase, which could replace squalane as the standard non-polar phase against which others are compared. It has a useful temperature range of 30-260° but is very expensive.

POLAR PHASES

Carbowax 20M is polyethylene glycol (average molecular weight 20 000) with general characteristics broadly similar to those of the polyethylene glycols of lower molecular weight. It has a maximum operating temperature of 225°. Carbowax 20M can be used for alkaloids and other basic drug separations. Peak shape of bases, e.g. amphetamine, can be improved by pre-coating the support with about 5% of potassium hydroxide.

Very durable and efficient capillary columns can be made from this phase. It is also used to deactivate capillary columns; it may be applied as a thin coating before the main stationary phase or vaporised into an already coated column from a small pre-column heated above the normal maximum operating temperature in the injection port.

OV-17 is phenylmethyl silicone, a useful, moderately polar, silicone phase with a high maximum operating temperature (350°). It is more oxygen-sensitive than most silicone phases and is available in capillary columns. A considerable amount of retention data for drugs on this phase has been published.

XE-60 is cyanoethyl silicone, a phase which was much favoured for steroid analysis and is widely used for capillary columns. It has a maximum operating temperature of 250°.

OV-225 is cyanopropyl phenylmethyl silicone; it is the modern counterpart of XE-60.

Polyesters. A large number of polyester phases have been used, particularly for the separation of fatty acid esters. These phases include neopentyl glycol

succinate, adipate, and sebacate; cyclohexanedimethyl adipate; and cyclohexanedimethyl succinate (CHDMS). This latter phase has been recommended for the analysis of underivatised barbiturates.

Poly amides. Poly A 103 is useful for the separation of barbiturates and of the tertiary amine tricyclic antidepressants.

Chirasil-Val is a unique chiral phase used in capillary columns for the separation of optical enantiomers. Most amino acids and many drugs containing polar functional groups may be resolved.

Mixed Phases. Mixtures of phases are sometimes used to tailor a column to solve a particular problem. The simultaneous separation of 11 of the commonly used anticonvulsant drugs and associated internal standards can be achieved using a mixture of *SP-2110* and *SP-2510-DA* which is commercially available.

Coating the Support Material

The two basic methods of applying the stationary phase material to the support material use either evaporation or filtration.

EVAPORATION

The support material is weighed into a flask which is sufficiently robust to withstand a vacuum. The amount of stationary phase to give the desired loading is dissolved in a suitable solvent and added to the support material in the flask. The choice of solvent is important and advice is given by most suppliers. A gentle vacuum is applied and the flask agitated, very gently, in a hot water-bath until the material is dry. This requires careful attention in the early stages to avoid foaming and loss of solution. With loadings up to 10%, the packing material should appear as a free-flowing powder. When dry, the powder is transferred to a dish and final drying is done overnight at 100°, with the exception of some oxygen-sensitive phases. If a rotary vacuum evaporator is used, the speed of rotation should be kept low to avoid mechanical damage to the particles of support material.

FILTRATION

The support material (usually 25 g) is weighed and suspended in a solution of stationary phase, the concentration of which should be approximately half the desired loading on the support material. A vacuum is applied to assist penetration, and after standing for a few minutes, the slurry is filtered on a Buchner funnel. The cake of coated support material is transferred to a dish and dried slowly initially,

then at 100°. If 25 g of support material and 100 ml of solution are used, the concentration on the support will be approximately twice that of the solution when Celite or Chromosorb W is used as support.

The exact amount can be determined either by evaporating the filtered solution and weighing the residue or by taking a small portion of the coated material and exhaustively extracting it. This method of coating is only for low-loaded supports and, with coatings of the order of 1 or 2%, generally gives a more even thin film than can be produced by the evaporation method.

Packing the Column

The empty column should be cleaned with detergent, dried, treated with 10% dichlorodimethyl-silane in toluene, rinsed with toluene and then with methanol, and dried again. A silanised glass wool plug is inserted in the detector end of the column and a vacuum line attached. Portions of packing material are gently poured into the injector end of the column through a funnel attached via a piece of rubber tubing. The column bed is built up gradually, about 10 cm at a time, by tapping with a pencil to consolidate the bed. The process is continued until the packing reaches the injection point, and a plug of silanised glass wool is added to secure the bed.

Capillary Columns

Capillary columns are available in glass (both soda and borosilicate), stainless steel, and silica (or natural quartz). Tubing of outside diameter of the order of 0.5 mm, internal diameter 0.2 to 0.4 mm, and 10 to 50 metres long is commonly used. Glass and silica are the materials of choice, stainless steel mainly finding application in the analysis of hydrocarbons. Silica columns are inherently straight and have the advantage of flexibility and strength, as long as the outside surface remains intact. A coating of heat-resistant polymer, usually polyimide, is applied to prevent damage. Silica columns may be threaded through complex pipework to emerge at the detector jet or mass spectrometer ion source. Capillary columns offer advantages, but are more demanding on instrumental design, and cannot be made in the laboratory without the purchase of a glass drawing machine to produce the tubing. The superior resolution available can be used to separate complex mixtures or to increase the certainty that a single compound is correctly identified. The high efficiency results in tall narrow peaks which considerably enhance the signal-to-noise ratio and consequently

the detection limits. Short columns (2-10 m) can be used to give similar resolution to packed columns, but in a shorter time.

It is usually necessary to modify the inside surface to assist wetting, e.g. by etching. If the glass surface itself is coated the column is referred to as a wall-coated open tubular (WCOT) column, whereas support-coated open tubular (SCOT) columns have a support bonded on to the glass walls, e.g. microcrystals of sodium or barium chloride.

Coating techniques aim to produce a uniform film 0.1 to 1.5 μm thick. High efficiency columns have a thin film, but at the cost of lower capacity and the risk of higher adsorptive activity of the column walls. Coating can be achieved either by a dynamic or by a static technique. The dynamic technique consists of forcing a concentrated solution (approximately 100 g/litre) of stationary phase in a suitable solvent through the column by gas pressure. Care is taken to ensure that the solution flows through the whole length of the column at a uniform velocity of 1 to 2 cm/sec. The gas flow is continued until all the solution has been voided and the temperature is then increased to evaporate the remaining solvent. If viscous solutions are used, a small amount of mercury may be added after the coating solution to prevent a thick film being deposited.

In the static technique, a dilute solution (approximately 10 g/litre) of the stationary phase is used to fill the column completely. One end is sealed, the column is placed in a water-bath and a vacuum line is attached to the other end to evaporate the solvent. It is important that no air bubbles or gaps exist in the column and that the solution is degassed, otherwise bumping takes place. There is much debate as to which method gives superior results, but each has its advocates. The dynamic technique is faster and is consequently used commercially.

Support-coated open tubular (SCOT) columns are prepared by similar techniques using a suspension of the support in the stationary phase solution.

INSTALLATION OF CAPILLARY COLUMNS

Glass columns, which are coiled when purchased, must have straight ends to allow them to fit into unions at the injector and detector. A device is commercially available to straighten capillary ends, but it is more usual to use a small butane flame. The column is suspended on a clamp stand and a supply of carrier gas is provided via a length of silicone rubber tubing to produce a flow of about 0.5 ml/min. A cool, small butane flame is used to apply

heat, starting a few centimetres from the end and working towards the open end. Gravity is allowed to perform the straightening while the gas flow sweeps pyrolysis products and mobilised stationary phase out of the column. The straightened portion should be inspected with a magnifying glass for constrictions or blockages. Some workers prefer to wash the stationary phase out of the column with solvent before straightening and to deactivate afterwards with silanising reagent.

Having straightened both ends, they may be presented to the fittings, when lengths and angles may be adjusted as necessary. Various fittings are available, but either graphite or Vespel (polyimide) ferrules are recommended. The injector end of the column should be fitted first, tightening the fittings just enough to prevent leakage when tested with a proprietary leak-testing fluid (not soap solution which leaves a residue). A low-volume (0.5 ml) bubble meter is used to check flow to ensure that the column is intact and not blocked. The detector end is then attached and checked for leaks. The column may lie or hang in the oven, but care should be taken to avoid cold spots. The detector is lit and the column tested at room temperature with an injection of 1 or 2 μl of methane, when a needle-sharp peak should be obtained. When the carrier gas pressure has been adjusted to give a velocity of approximately 15 cm/sec for nitrogen or approximately 30 cm/sec for helium, the column may be heated and a test mixture injected. Commercial columns are often supplied with a test mixture and a chromatogram obtained with the mixture. It should be possible to obtain performance equal to or better than the supplied chromatogram.

Various test mixtures are used, including a mixture of dimethylphenol and dimethylaniline with straight-chain paraffins. Any acidity or alkalinity of the column is apparent by loss of peak shape of the amine or phenol. The efficiency obtained will be a function of the entire chromatographic system. Poor efficiency or peak shape is often due to non-swept volume somewhere in the system. It may be necessary to add additional gas to the column outlet to ensure that the detector is effectively purged because most detectors are designed to operate with packed columns and a flow rate of about 30 ml/min, as opposed to the 1 or 2 ml/min delivered by a capillary column.

Column Conditioning

A new column requires conditioning before use. Volatile impurities remaining from the deactivation

of the support, and the coating and packing processes must be removed before the column is put into service. The detector should be disconnected and, with the column at room temperature, a flow of carrier gas of 10-20 ml/min should be maintained for an hour to purge oxygen from the system. The temperature may then be raised by about 25° every 30 minutes if an isothermal oven is used, or by 1°/min if a temperature programmer is available. When a temperature about 20° above the desired operating temperature has been reached the column is left for 12 hours. Care must be taken not to exceed the maximum operating temperature. Some phases (e.g. OV-17) are particularly oxygen-sensitive and can be ruined by careless conditioning. A constrictor fitted to the detector end of the column will help prevent back diffusion of oxygen.

Maximum Operating Temperatures

Maximum operating temperatures are usually quoted assuming isothermal operation with a flame ionisation detector. Other detectors may impose different limits, the mass spectrometer being much more susceptible to bleeding of the stationary phase than the thermal conductivity detector. All phases will bleed very slightly at high temperatures although normally this is not noticeable. Operating temperature has a profound effect on column life, particularly for capillary columns. Loss of stationary phase, or breakdown of the thin film into pools of the phase, expose the tubing surface resulting in serious loss of performance. The temperature limit of a column may be determined by the deactivation procedure used in production, rather than by the stationary phase itself. The newer silica columns have a very low metal oxide content, thought to act as a catalyst for the degradation of both sample and stationary phase, thus enabling phases to be run at higher temperatures. These columns have a protective external coating of polyimide which is slowly degraded at elevated temperatures and this can also limit column life. However, separations are usually achieved at lower temperatures on capillary columns than on packed columns.

Detectors

THERMAL CONDUCTIVITY DETECTOR (TCD)

This consists of a pair of heated filaments, each as the arm of a Wheatstone bridge, over which the column effluent and a reference gas stream flow. When a compound reaches the filament, the thermal conductivity is changed and the resulting change in temperature of the wire causes a change in

resistance. This change unbalances the bridge to provide the signal. This detector is used for the analysis of permanent gases and in cases where the amount of sample is not limited. The detector will respond to all gases and vapours with a thermal conductivity different from that of the carrier. The disadvantages include a rather low sensitivity and a critical dependence on temperature stability and gas flow.

FLAME IONISATION DETECTOR (FID)

This detector is probably the most widely used of all detectors since it responds to nearly all classes of compound.

The effluent from the column is mixed with hydrogen and the mixture burnt at a small jet in a flow of air. Above the jet is the collector electrode (a wire or ring around the jet) and a polarising potential of about 150 volts is applied between the jet and the electrode. When a component elutes from the column it is burnt in the flame and the resulting ions carry a current between the electrodes which provides the signal.

The detector need not be physically small since the effective volume is approximately that of the flame and is usually only a few microlitres. The background current is very low (10^{-12} amp) as is the noise level (10^{-14} amp). Any of the usual carrier gases can be used and minor changes in gas flow are without effect. The flow of hydrogen should be approximately equal to the carrier flow and an air supply of about 20 times the carrier flow is necessary to purge the detector adequately. Sensitivity is very high and less than 10^{-12} g per ml of carrier gas can be detected. Linearity is remarkable, as high as six orders of magnitude.

The response of the flame ionisation detector is roughly dependent on the number of carbon atoms in the molecule, but the response is lower if oxygen or nitrogen are also present in the molecule. It will respond to all organic compounds containing carbon-hydrogen bonds with the exception of formic acid. The insensitivity of the detector to water is a most useful feature which allows aqueous solutions to be used.

ALKALI FLAME IONISATION DETECTOR (AFID)

The introduction of alkali metal vapours into the flame of a flame ionisation detector confers an enhanced response to compounds containing phosphorus and nitrogen. By adjustment of operating conditions the detector can be made virtually specific for phosphorus compounds, e.g. a phosphorus : carbon response ratio of 50 000:1 and a phosphorus :

nitrogen response ratio of 100:1. Even when optimised for nitrogen compounds it retains its response to phosphorus, e.g. a nitrogen: carbon response ratio of 5000:1 and a nitrogen: phosphorus response ratio of 10:1.

Modern versions of this detector have an electrically heated rubidium silicate source of metal ions. The detector is particularly useful for drug analysis since most drugs contain nitrogen, while the solvent and the bulk of the co-extracted material from a biological sample do not.

This detector is especially useful for the detection of pesticides containing phosphorus. The extreme sensitivity to compounds containing phosphorus can be further exploited by the preparation of derivatives containing this element.

ELECTRON CAPTURE DETECTOR (ECD)

This is a selective detector which is very highly sensitive to compounds with a high affinity for electrons. Compounds containing a halogen, nitro group, or a carbonyl group are detected at very low concentrations.

The early form of this detector consisted of a small chamber with two electrodes parallel to each other and a radioactive source, usually ^{63}Ni , placed close to the cathode to ionise the carrier gas. A potential (2-30 volts) applied to the electrodes produces a steady background current. When an electron-capturing substance appears in the chamber some of the electrons are removed and a fall in the detector current results. The response of the detector is therefore a loss of signal rather than an increase in signal as given by most other detectors. More recent designs use concentric electrodes instead of parallel plates. Although the electron capture detector can be polarised from a suitable low voltage direct current supply, it is more sensitive when a pulsed power supply is used. The voltage is applied for a period of 0.5 to 10 microseconds, with an interval between the pulses of 5 to 500 microseconds.

Unfortunately the detector is markedly non-linear when operated in either pulsed or direct current mode. However, modern detectors can be operated in a constant current mode, the polarising pulses being modulated to maintain a constant current. A voltage dependent on the modulation frequency is generated as the output signal. Linearity is markedly improved, typically by 10^4 .

If a small amount of a quench gas such as methane is added to the carrier the stability and linearity of the detector are increased. If argon or helium is used the

addition of a quenching agent is essential. Additional carrier gas, usually referred to as 'make-up gas', can be added at the detector end of the column. With low column flow rates, as with capillary columns, 'make-up gas' may be necessary to purge the detector adequately and thus avoid peak broadening and distortion.

The selectivity of the electron capture detector, coupled with its extreme sensitivity (down to 1 pg), makes it very useful for compounds such as the benzodiazepines or halogenated pesticides. Alternatively, the great sensitivity of the detector may be utilised by preparing derivatives with reagents such as heptafluorobutyric anhydride. For some compounds the sensitivity of this detector may exceed that of the mass spectrometer.

PHOTOIONISATION DETECTOR (PID)

This uses ultraviolet radiation to produce ionised species which can be collected and detected as a current. Lamps of various energies (8.3, 9.5, 10.2, 11.7 eV) can be used to change the selectivity of the detector. Sensitivity is of the same order as the flame ionisation detector for amenable compounds, although it can be as low as 2 pg for benzene, with a dynamic range of 7 orders of magnitude.

The 11.7 eV lamp gives an almost universal response to hydrocarbons, whereas lamps of lower energy give some degree of selectivity. Compounds with an ionisation potential below that of the lamp will not be detected. Substances such as formaldehyde, hydrogen sulphide, nitrous oxide, tetraethyl lead, phosphine, and ammonia can be detected at better sensitivities and wider dynamic range than with other detectors. The barbiturates can be detected at lower levels than with the flame ionisation detector.

FLAME PHOTOMETRIC DETECTOR (FPD)

This detector burns the column effluent in a hydrogen-rich (reducing) flame and the optical emission is monitored by photomultiplier tubes through interference filters. A filter of 394 nm makes the detector almost totally specific for sulphur, while a filter of 526 nm confers selectivity for phosphorus. For example, with a 394 nm filter the sulphur: phosphorus response ratio is 10 000:1, and with a 526 nm filter the phosphorus: sulphur response ratio is 10:1.

Two photomultiplier filter combinations can be used to obtain the phosphorus and sulphur outputs simultaneously. However, its use for phosphorus is rendered obsolete by the more robust alkali flame ionisation detector, although it is still used for

sulphur. In the sulphur mode the output is proportional to the square of the sulphur concentration, although modern electronics can linearise this output.

ELECTROLYTIC CONDUCTIVITY DETECTOR

In this detector, column effluent is mixed with a reaction gas (air or hydrogen) and passed into a reactor at 800° containing a catalyst to convert eluting components into conducting species. Interferences are removed by a scrubber placed between the reactor and the conductivity cell. The gas stream then enters a conductivity cell where components dissolve in the circulating electrolyte. The conductivity of this solution is compared with that of the electrolyte alone and the difference provides the output of the detector.

The detector is truly specific for halogens (unlike the electron capture detector), the chlorine: carbon response ratio being $1 \times 10^6:1$; it is also specific for nitrogen (unlike the alkali flame ionisation detector), the nitrogen: carbon response ratio also being $1 \times 10^6:1$. For sulphur the detector is of the same order of sensitivity as the flame photometric detector but gives a linear output, the sulphur: carbon (except carbon dioxide) response ratio being $1 \times 10^5:1$. It is comparable in sensitivity to the thermal energy analyser for low molecular weight nitrosamines, the nitrosamines: other nitrogenous compounds response ratio being 500:1. The detection of nitrosamines and the specificity for halogens ensure the continued use of this detector.

MASS SPECTROMETRY

The quadrupole or dodecapole mass spectrometer is an ideal detector as the chromatograph is an almost ideal inlet device for the mass spectrometer. The ability to scan a spectrum rapidly (typically 2 s for a mass range of 50 to 500 mass units), and the tolerance to relatively high source pressure (1×10^{-5} torr) make interfacing quite simple (see under Mass Spectrometry, p. 252).

DUAL DETECTOR SYSTEMS

The use of detectors such as the electron capture detector (ECD) for the identification of amenable compounds and the alkali flame ionisation detector (AFID) for the detection of compounds containing phosphorus and nitrogen, removes many of the extraneous peaks frequently observed when non-selective detectors such as the flame ionisation

Fig. 1. Chromatograms, using both FID and ECD, of an extract of a blood sample from a patient taking flurazepam who had a blood transfusion. A, di(2-ethylhexyl) phthalate from the polyvinyl chloride transfusion bag; B, *N*¹-desalkylflurazepam; C, prazepam (internal standard); D, cholesterol.

detector (FID) are used. However, although the use of these selective detectors has increased the sensitivity of detection of many drug groups, it has

Fig. 2. Chromatograms, using FID and AFID in nitrogen mode, of an extract of a blood sample containing barbiturates. The attenuations were adjusted to give approximately equal-sized peaks for the barbiturates on both detectors. The contamination from tri-isobutyl phosphate introduced from the filter paper is apparent. A, tri-isobutyl phosphate; B, amylobarbitone; C, quinalbarbitone; D, $C_{19}H_{40}$ (retention index marker).

exchanged one set of problems for another. Hitherto undetected non-drug substances are now observed which interfere in many toxicological analyses.

The simultaneous use of a combination of a universal detector (FID) and a specific detector to monitor the effluent of a column can provide useful information about the properties of functional groups and substituents in a molecule.

The FID response is roughly dependent on the number of carbon atoms in a molecule and is quite predictable. However, the ECD response varies widely for different compounds, is dependent on the electron-deficient part of the compound, and is difficult to predict. The AFID response of a compound depends to some extent on the number of phosphorus or nitrogen atoms in a molecule, but it also depends on their environment. Thus, by using the FID as a reference and measuring the ECD or AFID response relative to it, another characteristic for identification is obtained in addition to retention behaviour.

The ECD is very sensitive to phthalate esters, for example di(2-ethylhexyl) phthalate which is a common contaminant of blood stored in polyvinyl chloride containers (Fig. 1). The AFID can be made virtually specific for phosphorus-containing compounds, but retains its capability to detect phosphorus even when optimised for nitrogen compounds. The contaminant tri-isobutyl phosphate from filter paper is not apparent when using the FID, but produces the largest peak on the chromatogram with the AFID in the nitrogen mode (Fig. 2).

Introduction of Samples

PACKED COLUMNS

Injection of the sample is usually made by means of a syringe and needle through a silicone-rubber septum. The sample may be injected either directly on to the column or into a heated zone in the gas stream before it enters the column. In the latter case the inlet port can be fitted with a removable glass liner to prevent non-volatile material contaminating the column. Unstable materials may be decomposed by the temperature of the injection system, particularly if the system is constructed of metal. For labile substances, the most satisfactory method is on-column injection. The injection port and the column must be in a straight line so that a long syringe needle can just enter the top of the column packing. This is the method of choice for many drugs, but clean extracts should be used to minimise column contamination.

Solids may be dissolved in a suitable solvent and injected with a microsyringe. It is better to keep the solution as concentrated as possible to reduce the size of the solvent peak. The small glass conical-bottomed tubes used for bacteriological agglutina-

tion tests (Dreyer tubes) are very cheap and will allow a large number of injections to be made from 0.05 ml of solution.

Liquids can be injected using a microsyringe of 1 to 10 μl capacity, but, with sensitive detection systems, it is necessary to dissolve the sample in a suitable solvent to reduce the sample size and avoid overloading the detector. Gases and vapours may be introduced by injection through the inlet port septum using a gas-tight syringe. Usual volumes are in the range 0.2 to 10 ml. A gas sampling valve is the method of choice for quantitative work or if much qualitative work is contemplated.

Head-space Analysis

This technique permits the detection of volatile substances in a liquid sample and minimises contamination of the column. A small volume (0.2 to 0.5 ml) of the sample is placed in a small vial (typically 7 ml) sealed with a septum disk which is faced with polytetrafluoroethylene, and the vial is equilibrated at an appropriate elevated temperature for about ten minutes. A sample of the vapour is removed with a syringe, taking care that no liquid is withdrawn, and is then injected on to the column. This technique is used in the assay of ethanol and other solvents in blood and for complex household preparations such as polishes, which contain volatile substances.

CAPILLARY COLUMNS

The low flow rate (about 2 ml/min) through open tubular columns poses constraints on injector design. To overcome this, either the volume of the injector must be decreased or the flow rate through it must be increased.

Split Injection

An inlet splitter allows a high flow through the injector while maintaining a low flow through the column, the excess gas and associated sample components being vented to the atmosphere. The ratio of these two flows (the split ratio) is the proportion of injected sample that reaches the column. The function of the splitter is not to reduce sample volume, but to ensure that the sample enters the column as a plug and is not exponentially diluted. The total flow through the injector may be from 10 to 400 ml/min giving split ratios of 10:1 to 500:1. A good splitter should be linear, that is it should split high- and low-boiling point compounds equally. However, it is rare to meet a sample with a large volatility range in drug analysis. At high split

ratios, large volumes of carrier gas flow through the splitter and care must be taken to ensure that it is adequately pre-heated. Choice of solvent and injector temperature are both important considerations.

Splitless Injection

Splitless injection may be either on-column, using a needle fine enough to enter the column bore, or off-column using a low-volume heated block. In either case the top of the column is held at a temperature low enough for the solvent containing the sample to condense. The solvent temporarily swamps the stationary phase and ensures that the sample components concentrate in a narrow band. Any solvent or sample remaining in the injector is back-flushed with carrier gas, often by automatic valves. The proximal end of the column is then rapidly brought to the operating temperature, when the solvent vaporises and chromatography begins. Care is necessary to select a suitable solvent with regard to boiling point, stationary phase, and sample composition. On-column injection syringes have stainless steel or silica needles which are too fine to penetrate a septum, and, in order to minimise carrier gas loss, valve assemblies are used which grip the needle or which only open when the needle is in the narrow entrance channel.

Solid Injection

When solvent interference is serious the sample may be injected as a solid. The 'moving needle' injector has found application in steroid analysis and for the determination of anticonvulsant drugs. A solution of the material to be injected is placed on the tip of the glass needle with a syringe. A small flow of carrier gas sweeps the solvent out of the top of the device to waste. The dry residue is then introduced by moving the needle into the heated injection zone of the chromatograph with a magnet. This form of injection can only be used with drugs which will not volatilise with the solvent.

Temperature Programming

For complex mixtures with components of widely varying retention characteristics, it is sometimes very difficult or impractical to choose a column temperature which will allow all the components to be resolved. It is therefore necessary to vary the column temperature throughout the analysis. Most instruments are available with a temperature programming option, a multi-ramp programmer being particularly useful for capillary chromatography. The first ramp can be used during splitless injection to

bring the column rapidly up to the initial chromatography temperature, followed by a slower analytical ramp to perform the separation. One problem with temperature programming is that the back-pressure increases with temperature and will reduce flow if a flow controller is not used. Column bleed will also increase, resulting in an increasing baseline. For this reason the column should be well conditioned at the upper temperature limit.

Gas Pressure and Flow Control

In order to perform accurate and reproducible gas chromatography it is necessary to maintain a constant carrier gas flow. Some detectors need additional gases which also require flow or pressure control. Under isothermal conditions simple pressure control is adequate for packed or capillary columns. However, the added convenience of a digital flow controller may be considered worthwhile. A pressure gauge between the flow controller and the injector will enable the back-pressure to be monitored, a decrease being symptomatic of a leaking septum and an increase suggesting contamination of the top of the column. It also serves to ensure that the flow controller is performing correctly. If the back-pressure rises to equal the supply pressure, then flow will become pressure controlled.

Flow control is highly desirable if not essential during temperature programming with packed columns and can be used to advantage with on-column injectors on capillary columns. Pressure control, with metal diaphragms, is the only practical means of gas control for capillary work with split injection.

Adequate gas control for flame ionisation detector gases is usually achieved by pressure regulators supplying gas via constrictors. Some alkali flame ionisation detectors require very precise control of hydrogen flow, best achieved by mass flow control.

Derivative Formation

The preparation of derivatives may be used to give additional evidence of identity or to improve gas chromatography characteristics. For identification purposes, the indication that specific functional groups are present and that derivative formation is possible may provide useful information. Although the retention characteristics are changed, the order of elution of a series of derivatives will be the same as for the parent compounds.

Derivative preparation can be used to shorten or lengthen the retention time of a substance and this can be helpful to remove the substance peak away

from interfering material or to speed the analysis. For instance, hydroxylated compounds often have long retention times and low sensitivity, and tailing may result. However, they readily form silyl ethers and these derivatives behave similarly to hydrocarbons.

Derivatives may also be used to make the molecule capable of detection by selective detectors. The reaction may be carried out during extraction (e.g. extractive methylation), on the dry residue (e.g. silylation), or during injection (e.g. methylation). If a compound requires derivatisation in order to reduce its polarity, the use of high pressure liquid chromatography should be considered instead of GLC, assuming that sensitivity is not the limiting factor.

SILYLATION

Most alcohols and phenols will form silyl ethers when treated with trimethylsilyl reagents at room temperature. Some compounds with sterically hindered hydroxy groups require heating. Since the reagents and the reaction products are very easily hydrolysed, it is essential that the glassware is dry and that water vapour is rigorously excluded. Hexamethyldisilazane will silylate many compounds, although *N,O*-bis(trimethylsilyl) trifluoro-acetamide is a more powerful reagent, especially when catalysed by 1% trimethylchlorosilane. *tert*-Butyldimethylsilylimidazole reacts in a similar manner to the other reagents, but forms ethers which are much more resistant to hydrolysis.

FORMATION OF IMINES (SCHIFF'S BASES)

Primary amines condense with aldehydes and ketones to form imines, and while many aldehydes and ketones can be used, those of large molecular weight usually give a poorer yield of the derivative. Acetone, isobutyl methyl ketone, and benzaldehyde usually form stable derivatives. Carbon disulphide can be used as a reagent to form isothiocyanate derivatives with primary amines. If a cyclic ketone such as cyclohexanone is used, the carbinolamine derivative will be formed. Ephedrine and other beta-hydroxylated secondary amines form oxazolidines when treated with ketones.

ACYLATION

Primary and secondary amines can be acylated readily by treatment with acid anhydrides and heat. Acetic anhydride, propionic anhydride, and trifluo-

roacetic anhydride react readily. Direct extractive acetylation using *N*-methylimidazole as catalyst has been reported for a number of drugs including paracetamol. Reagents for preparing electron-capturing derivatives include trifluoroacetic anhydride, heptafluorobutyric anhydride, and pentafluoro-robenzoic anhydride.

METHYLATION

On-column methylation of barbiturates, hydan-toins, and some carboxylic acids can be achieved by injecting the sample mixed with 0.2M trimethylanilinium hydroxide in methanol. For carboxylic acids, the sample can be dissolved in 14% boron trifluoride in methanol and heated at 60 to 100° for 30 minutes. After evaporation of the bulk of the methanol, the mixture is diluted with a few millilitres of water and the methyl derivative extracted with a small volume of hexane.

The use of trimethylanilinium hydroxide can cause a problem. Highly polar material which has not been fully methylated can lie dormant on a column for a long period of time, but can be released by a subsequent injection of trimethylanilinium hydroxide, thus yielding a false positive result.

The toxic and potentially explosive diazomethane may be used for the methylation of drugs, including the barbiturates. The reaction is rapid and can be carried out by dissolving the compound in a few hundred microlitres of an ethereal solution of diazomethane and removing excess reagent with a stream of nitrogen. Diazomethane has the advantage of being clean and fast.

Evaluation of Chromatographic Performance

The evaluation of the performance of the column, whether capillary or packed, is made on the basis of its efficiency (the narrowness of a peak) and the peak shape (i.e. whether it tails or fronts). A well packed column in a well designed system should give symmetrical peaks, as tailing or fronting will adversely affect resolution. Tailing may result from non-swept volume in the system or from component/stationary phase or component/support interactions. The tailing of polar compounds can often be remedied by the use of a more polar stationary phase. Fronting usually results from overloading, particularly with capillary columns.

Peak shape is usually expressed by the peak asymmetry (A_s). In Fig. 3, the peak asymmetry factor for substance B is given by

$$A_s = \frac{YZ}{XY}$$

where a vertical line is drawn through the peak maximum and XYZ is drawn at 10% of the peak height. A symmetrical peak has $A_s = 1$. Efficiency is dependent on the degree of band broadening relative to the time taken to elute. It is measured in theoretical plates (N) by analogy with distillation. For a particular substance, this can be calculated by

$$N = 16 \left[\frac{t_R}{W} \right]^2 \quad \text{or} \quad N = 5.54 \left[\frac{t_R}{W_{1/2}} \right]^2$$

where t_R = time from injection to peak maximum for the substance, W = idealised peak width at base, $W_{1/2}$ = peak width at half height. Since N is dimensionless, any units can be used to measure t_R , W , or $W_{1/2}$ as long as they are consistent. Efficiency is usually quoted in plates per metre, or as height equivalent to a theoretical plate (HETP) (h), i.e. the length of column required to generate one plate. It is defined by

$$h = \frac{L}{N}$$

where L is the length of the column.

Fig. 3. Chromatogram for two compounds, A and B, showing measurement of significant parameters. W , width at the base of the peak; $W_{1/2}$, width at half peak-height; $t_R(A)$ and $t_R(B)$, retention times of A and B, respectively; Δt_R , the difference in retention time between A and B; XYZ, a line drawn at 10% of the peak height.

With long and very efficient columns, the time taken for a non-retained compound to reach the end of the column after injection (dead-time) can be several minutes. It is determined by injecting a compound such as methane for a flame ionisation detector or methylene chloride for an electron capture detector. Retention times should really compensate for the dead-time rather than being

measured from the time of injection, and this is especially important when measuring efficiency, which should be measured using a compound with a retention time at least four times the dead-time. A useful concept is the separation number (TZ), after Trennzahl who formulated it. It is a measure of how many resolved peaks can be accommodated between adjacent members of an homologous series; any series can be used. The separation number for A and B which are two members of an homologous series differing by one methylene group (Fig. 3) is given by

$$TZ = \frac{\Delta t_R}{W_{1/2}(A) + W_{1/2}(B)} - 1$$

where Δt_R is the difference in retention time between A and B, and $W_{1/2}(A)$ and $W_{1/2}(B)$ are their peak widths at half height respectively. If $TZ=0$, no other peak will fit between the two homologues; if $TZ = 1$, then one peak will fit. For most applications in drug analysis the chromatogram will only contain two or three compounds of interest, but an efficient column will maximise the probability that a peak consists of only one compound and that it is the compound of interest.

Retention Index

In order to be able to communicate gas chromatographic retention data between laboratories, it is necessary to use a means of recording data that is independent of the instrument used. Relative retention time, that is the retention time of the sample relative to that of a reference compound, has been used.

However, the concept of retention index has been shown to be more universal in its application. This system uses a homologous series of *n*-paraffins to provide the reference points on the scale (E. Kovats, *Z. analyt. Chem.*, 1961, 181, 351-366). For any column temperature and stationary phase, the elution times of members of a series of *n*-paraffin homologues are assumed to increase by an index of 100 for each additional methylene unit. On this scale, H_2 has an index of zero, methane has an index of 100, ethane of 200, and so on up the scale of paraffins. This method produces a scale against which unknown substances are measured, and the variations in retention time, which are frequently very considerable, are obviated. The method is illustrated in Fig. 4, where phenobarbitone has a retention time of 4.5 minutes and a retention index of 1957.

Fig. 4. The determination of the retention index of phenobarbitone from a plot of an homologous series of *n*-paraffins.

Retention indices collected from many sources (R. E. Ardrey *et al.*, *J. Chromat.*, 1981, 220, 195-252) show remarkable agreement, even when measurements were made on different (though equivalent) phases and at different temperatures. As is to be expected, there is better agreement for non-polar (most hydrocarbon-like) compounds than for polar compounds.

In practice, for isothermal chromatography, the retention index (RI) is found by logarithmic interpolation between *n*-paraffins that bracket the compound. Retention index =

$$100(P_{z+n} - P_z) \times \frac{\log t_R(x) - \log t_R(P_z)}{\log t_R(P_{z+n}) - \log t_R(P_z)} + 100P_z$$

where P_z = carbon number of small paraffin, P_{z+n} = carbon number of large paraffin, t_R = retention time, and x = unknown compound. There is an approximately linear relationship between the retention time and chain length during linear temperature programming if all peaks elute on the same ramp, and this can be used to calculate RI.

Quantitative Determinations

Quantitative work usually requires some form of sample preparation to isolate the drug from the bulk of the sample and some degree of concentration or, more rarely, dilution. These processes will

inevitably introduce some degree of analytical error. A further difficulty is caused by the non-reproducibility of injected volumes. In order to compensate for these errors, it is usual to compare the response of the unknown with the response of an added internal standard. The internal standard should be added as early as possible in the assay process and should have chromatographic properties as close as possible to the drug, preferably with a longer retention time. It is often possible to obtain unmarketed analogues of drugs, or compounds specially synthesised for use as internal standards. However, the internal standard will not behave exactly as the drug and careful control of variables, such as pH, is necessary. If a derivative is to be prepared, the standard should also be derivatisable. An inappropriate internal standard can seriously affect precision (K. H. Dudley, *Trace Organic Sample Handling*, in *Methodological Surveys Sub-series (A)*, Vol. 10, E. Reid (Ed.), Chichester U.K., Ellis Horwood, 1980, p. 336).

If a mass spectrometer is being used as the detector, then the ideal internal standard is a ^{13}C analogue of the drug.

Calibration should include points of higher and lower concentrations than the sample, and quality assessment samples should be included at appropriate concentrations in frequently run assays. Peak measurement may be by peak height or by the peak area obtained by integration. The plot of the ratio of peak height (or area) of the drug to internal standard versus concentration will be a straight line with most detectors.

Practical Points

Carrier gas flow should be optimised for a particular column and a particular carrier gas. This is most important for open tubular columns. Fig. 5 shows the relationship between efficiency expressed as the height equivalent of a theoretical plate versus carrier gas velocity (Van Deemter plot) for a 28 m by 0.25 mm internal diameter wall-coated open tubular column of Carbowax 20M.

It is unwise to assume that published conditions will be correct for any chromatographic system. They may be accurate; on the other hand they may be no more accurate than the calibration of the oven controller or flow meter on the particular instrument. In general, retention times double with a decrease in temperature of 20° . For a particular separation, the lowest temperature compatible with a reasonable analysis

Fig. 5. Van Deemter plots for a 28 m by 0.25 mm internal diameter wall-coated open tubular column coated with Carbowax 20M run with different carrier gases.

time should be used. If the time is excessive, it is generally better to reduce the stationary phase loading than to increase the column temperature.

There is a maximum temperature at which a column can be operated and there is also a minimum temperature below which the efficiency will drop sharply. The stationary phase must be a liquid at the temperature of operation, and if a column is run at too low a temperature to obtain longer retention times the stationary phase may still be in the solid or semi-solid form.

To ensure even packing of the column the particle size should not exceed 1/20th of the column diameter or there may be some loss of efficiency. The particle size distribution should be as small as possible.

If trace impurities are sought in the presence of a preponderant component, a number of stationary phases of differing polarities should be tried. Trace impurities are easily seen if they emerge before the main component of a mixture, while they may be completely lost in the tail if they come just after the large peak. Early peaks are also sharper and thus, for the same peak area, will be higher, and this effect can contribute enormously to the successful detection of trace substances.

The solvent used for the sample can sometimes

produce unexpected derivatives that give different retention times. An inert non-polar solvent should be used if possible. However, acetone, other ketones, and carbon disulphide readily form derivatives with primary amines.

The gas used as the mobile phase is of minor importance when using packed columns, but has a greater effect with capillary columns.

Modifying the mobile phase in gas chromatography has very little effect compared with that observed with HPLC or TLC and, in general, affects efficiency rather than selectivity. Nitrogen gives higher efficiency, but at the expense of longer analysis time, while the less dense but hazardous hydrogen gives lower efficiency but faster analysis. In practice, nitrogen is usually used for packed columns and helium for capillary columns. Certain detectors impose restrictions on the choice of carrier gas, but an additional supply of gas can be added to the column effluent to purge the detector. The presence of traces of oxygen or water vapour in the carrier gas will drastically shorten column life. Metal hydride filters (to remove oxygen) and molecular sieves (to remove water vapour) are strongly recommended.

If dirty samples have been injected, the top of the column may show marked deterioration. The top few centimetres of packing should then be replaced with fresh packing, the glass wool should be replaced with new material, and the column reconditioned. Similarly, after continual use a capillary column may often have its former performance restored by removing the first coil with no significant loss of efficiency.

GAS CHROMATOGRAPHY SYSTEMS

The systems given below have been chosen because of their applicability to routine screening, separating, and identifying drugs. The drugs are divided into chemical or pharmacological groups, but some other drugs are also included if they are chemically similar and would be extracted with that group, e.g. apomorphine and naloxone are included in the narcotic analgesics. References to specific systems for the quantification of individual drugs or groups of drugs are given in the monographs in Part 2.

The most general screening system is one using a dimethylsilicone stationary phase such as SE-30, OV-1, or OV-101. This should always be used for screening purposes since it has the greatest chance of eluting any compound of interest. The support should always be a high performance support to eliminate any of its adsorptive effects. Treatment

of the support with potassium hydroxide will ensure that amines give better peak shapes, but at the expense of not being able to elute acids and phenols. If an untreated column is used for chromatographing basic extracts, then acidic compounds such as barbiturates will not be eluted because a small amount of alkaline hydroxide will accumulate at the beginning of the column.

Most of the data are for the drugs themselves, but thermal decomposition may occur and the peak observed may be for the decomposition product rather than the original drug. Where the drug is known to chromatograph badly, or to decompose, data are given for the derivatives, e.g. methyl esters for the sulphonamides.

Wherever possible the retention index of the drug is given. This is a more reproducible retention parameter than retention time or relative retention time and is practically independent of support, loading of phase, and temperature. However, if a laboratory routinely prefers to use these parameters, the retention index data can easily be converted by chromatographing a few representative drugs and using a calibration graph or linear regression analysis of retention indices against retention times or relative retention times. The retention indices on low polarity stationary phases are very similar, so that those for SE-30 can often also be used for Apiezon L etc. Retention indices for non-drug substances that may interfere with toxicological analyses, but are not included in this book, may be found in R. E. Ardrey and A. C. Moffat, *J. Chromat.*, 1981, 220, 195-252 and J. Ramsey *et al.*, *J. Chromat.*, 1980, 184, 185-206.

An alkali flame ionisation detector is the best detector for nitrogenous drugs, but a flame ionisation detector should always be used as well, since many drugs do not contain nitrogen, e.g. some anti-inflammatory agents. Electron capture detectors are excellent for benzodiazepines and halogen-containing compounds such as the phenothiazines. Extra selectivity can always be obtained by using element-specific detectors, e.g. those for phosphorus and sulphur for compounds containing those elements.

NOTE. In the tables of retention indices, a dash indicates that no value is available for the compound, not that it does not elute.

GENERAL SCREEN

System GA

R. E. Ardrey and A. C. Moffat, *J. Chromat.*, 1981, 220, 195-252.

This system may be used for most thermally stable drugs. Because the stated values for drugs are retention indices, the operating conditions for the SE-30 column may be varied to suit particular laboratory situations.

COLUMN. 2.5% SE-30 on 80-100 mesh Chromosorb G (acid-washed and dimethyldichlorosilane-treated), 2 m x 4 mm internal diameter glass column. It is essential that the support is fully deactivated.

COLUMN TEMPERATURE. Normally between 100° and 300°. As an approximate guide, the temperature to use is the retention index —10.

CARRIER GAS. Nitrogen at 45 ml/min.

REFERENCE COMPOUNDS. *n*-Alkanes with an even number of carbon atoms.

RETENTION INDICES. Values for drugs in this system will be found in drug monographs and in the indexes to Analytical Data in Part 3; they are also included in the systems for specific groups of drugs which follow.

AMPHETAMINES, OTHER STIMULANTS, AND ANORECTICS

System GA, previously described, may be used, or Systems GB or GC, below. System GA produces tailing peaks with these compounds.

System GB

D. A. Cowan, personal communication.

COLUMN. 10% Apiezon L and 2% KOH on 80-100 mesh Chromosorb W HP, 2 m x 3 mm internal diameter glass column.

COLUMN TEMPERATURE. Programmed at 16° per minute from 170° to 260° and held for 8 minutes.

CARRIER GAS. Nitrogen at 30 ml/min.

REFERENCE COMPOUNDS. *n*-Alkanes with an even number of carbon atoms, or use retention times relative to diphenylamine (RI 1680).

System GC

D. A. Cowan, personal communication.

In this system, the drugs are chromatographed as tertiary bases or trifluoroacetyl derivatives (see p.188).

COLUMN. 3% OV-17 on 80-100 mesh Chromosorb W HP, 2 m x 3 mm internal diameter glass column.

COLUMN TEMPERATURE. 170° for 2 minutes and then programmed at 16° per minute to 270° and

held for 8 minutes.

CARRIER GAS. Nitrogen at 30 ml/min.

REFERENCE COMPOUNDS. *n*-Alkanes with an even number of carbon atoms.

RETENTION INDICES. The retention indices given for System GC are those of the tertiary bases or of trifluoroacetyl derivatives.

ANALGESICS, NON-STEROIDAL ANTI-INFLAMMATORY DRUGS, AND OTHER STRONGLY ACIDIC DRUGS

System GA, previously described, may be used, or System GD, below.

System GD

In this system, the substances are chromatographed as their methyl derivatives (see p. 189).

COLUMN. 3% SE-30 on 80-100 mesh Chromosorb G (acid-washed and dimethyldichlorosilane-treated), 2 m × 3 mm internal diameter glass column.

COLUMN TEMPERATURE. 120° for 2 minutes and then programmed at 10° per minute to 260° and held for 5 minutes.

CARRIER GAS. Nitrogen at 40 ml/min.

REFERENCE COMPOUND. Hexadecane ($n\text{-C}_{16}\text{H}_{34}$).

Note. Free carboxylic acids and phenols will not generally give peaks although large quantities may give tailing peaks.

RETENTION INDICES AND RELATIVE RETENTION TIMES. The values given for System GD are retention times of methyl derivatives relative to $n\text{-C}_{16}\text{H}_{34}$.

ANTICONVULSANTS

System GA, previously described, may be used, or System GE, below.

System GE

Quantitative Analysis of Underivatised Antiepileptic Drugs, Supeico Bulletin 779, 1979, Supeico Inc., Bellefonte, Pennsylvania 16823.

COLUMN. 2% SP-2110 and 1% SP-2510-DA on 100-120 mesh Supelcoport, 1 m × 2 mm internal diameter glass column.

COLUMN TEMPERATURE. Programmed at 16° per minute from 120° to 250°.

CARRIER GAS. Nitrogen at 50 ml/min.

REFERENCE COMPOUND. Phenytoin.

Note. This system separates cholesterol from all drugs in the group.

RETENTION INDICES AND RELATIVE RETENTION TIMES.

The values given for System GE are retention times relative to phenytoin.

BENZODIAZEPINES

System GA, previously described, may be used, or System GG, below

System GG

M. Moller, personal communication.

COLUMN. 2.5% OV-17 on 80-100 mesh Chromosorb G, treatment and dimensions as for System GA.

COLUMN TEMPERATURE, CARRIER GAS, REFERENCE COMPOUNDS. As for System GA.

RETENTION INDICES. The retention indices of benzodiazepines have been shown to be dependent on column temperature (H. Schuetz and V. Westenberg, *Z. Rechtsmed.*, 1978, 82, 43-53 and J. *Chromat.*, 1979, 169, 409-411). The values given by these authors are about 50 retention index units above those generally quoted. The values given below should therefore be checked before use by chromatographing a few sample compounds.

	System

High Pressure Liquid Chromatography

R. Gill

The modern form of column liquid chromatography has been called high-performance, high-pressure, high-resolution, and high-speed liquid chromatography. However, the abbreviation HPLC is now universally understood to describe the technique that separates mixtures on columns filled with small particles (typically 10 μm or less diameter) by elution with a liquid under high pressure. The essential equipment consists of an eluent reservoir, a high-pressure pump, an injector for introducing the sample, a stainless steel column containing the packing material, a detector, and a chart recorder. Thus, HPLC is similar to other types of chromatography in having a stationary phase (packing material) and a mobile phase (eluent).

HPLC equipment can be obtained as a complete system or assembled from individual modules (pump, injector, detector, etc.). Modular systems are generally more convenient because units (especially detectors) can be interchanged between chromatographs and new modules can be added to update the equipment. Modules are usually linked with standard stainless steel tubing of 1/16 in (about 1.6mm) outside diameter so that the coupling of units from different manufacturers is straightforward. However, tubing between the column and detector can be either stainless steel or polytetrafluoroethylene (PTFE). Various compression fittings (using nuts and ferrules) are available for making connections.

Columns

The columns are usually constructed from straight stainless steel tubing having a polished inner surface. Columns 10 to 30 cm long with an internal diameter of 4.5 to 5 mm and an outside diameter of 1/2 in (6.3mm) are normally used. The outlet is terminated by a stainless steel mesh disk to retain the packing material. The mesh disk is held in position by the 'end-fitting' with the end of the tubing to the detector flush against the centre. This tubing should have an internal diameter of 0.25 mm or less and be as short as possible to minimise peak broadening.

Injection Systems

Valve injectors consist of switching valves connected to a loop of stainless steel tubing (sample loop). A short tube (0.25 mm or less internal diameter) connects the injector with the top of the column where the end-fitting is identical with that at the bottom. The sample is introduced into the loop when the valve is in the 'load' position, while the eluent flows from the pump to the column through another passage within the valve. When the valve is switched to 'inject', the loop is connected into the line of flow between pump and column. The best quantitative reproducibility is achieved by using a loop of the required volume which is completely filled with sample. However, the sample can be loaded with a graduated syringe to partially fill the loop.

When *syringe injection* is used, the top 5 to 10 mm depth of packing is removed from the column, a stainless steel mesh is placed in position, and the remaining space filled with glass beads (typically 200 μm diameter). The top of the column is then connected directly to the injection device. Such injectors allow the sample to be deposited in the layer of glass beads when the tip of the syringe needle is centrally positioned just above the upper mesh. There are two types of injector used for syringe injection. In a 'stop-flow' injector the pump is switched off and the eluent flow is allowed to subside. A valve is then opened and the syringe needle inserted through a needle guide to deposit the sample. After closing the valve the pump is restarted. A second type of syringe injector allows the sample to be injected without stopping the pump, the syringe needle being inserted through a rubber septum.

Syringe injectors can achieve slightly better column efficiencies than valve injectors and they also cost less. Nevertheless, syringe injectors have several disadvantages. In septum injection, pieces of rubber are often deposited in the glass bead layer which can lead to blockage of syringe needles. Furthermore, the septa have a pressure limitation of about 1500 lb/in² (10.3 MPa). This pressure limit can be overcome by using the 'stop-flow' method; however,

stopping the pump can lead to disturbances of the baseline. Valve injectors are more robust, require less maintenance, and are generally preferred for routine drug analysis.

Pumps

The flow rate through the column is generally between 1 and 3 ml/min, with pressures ranging from 500 to 4000 lb/in² (3.4 to 27.6 MPa). The pumps must show minimum fluctuations within these ranges to achieve maximum stability of the detector response and reproducible retention data. Pumps are either 'constant-pressure' or 'constant-flow', the constant-flow pumps being generally more convenient as changes in column resistance or eluent viscosity are compensated by changes in operating pressure.

The most simple 'pump' consists of the direct application of gas pressure (from a cylinder of compressed nitrogen or air) on to the surface of the eluent contained in a pressure bottle or holding coil. Such devices are relatively cheap but have the disadvantages that the pressure limit is low (typically 1500 lb/in², 10.3 MPa), the gas dissolved in the eluent may reappear as bubbles in the detector flow-cell, and a change of eluent requires the apparatus to be dismantled, washed, and refilled. Commercial HPLC pumps use pistons or diaphragms to displace eluent, hence avoiding the problem of dissolved gas. Syringe pumps are of the constant-flow type and have a large piston which is moved at a constant speed by an electric motor. They produce a very smooth flow but the syringe has limited capacity and needs to be manually refilled at the end of each piston stroke. Pneumatic amplifier pumps are of the constant-pressure type with the piston driven by compressed gas. Check valves allow the piston to return to its starting position at the end of each stroke, drawing eluent from a solvent reservoir into the pump.

The most widely used pumps are electrical reciprocating pumps. They are constant-flow pumps with small piston displacements (typically 100 μ l) and with check valves to allow eluent to be drawn from a reservoir. Flow rate can be controlled by having a constant speed motor with mechanical adjustment of the piston stroke length, or by having a variable speed motor with constant stroke length. The small internal volume allows a rapid change from one eluent to another. Such single piston pumps produce a pulsating flow and, although the column itself causes considerable damping, other damping

devices are generally included. Nevertheless, the smooth flow necessary for detection at very high sensitivities generally requires a pump with 2 or 3 piston heads working out of phase.

Detectors

Four detectors have found widespread application. These are the ultraviolet-visible detector, the fluorescence detector, the refractive index detector, and the electrochemical detector. Only the refractive index detector can be considered as a 'universal' detector as virtually all compounds cause a change in refractive index when dissolved in an eluent. The other three types depend upon the specific properties of the solute rather than changes in the bulk properties of the eluent. Hence, these detectors can confer various degrees of selectivity to the analysis.

An important factor in the choice of a detector is the amount of peak broadening which occurs as the eluted compounds pass through. This is largely controlled by the volume and geometry of the detector flow-cell but is also influenced by the connecting tubing between the column and the detector.

ULTRAVIOLET-VISIBLE DETECTORS

Most applications in drug analysis use detectors which respond to the absorption of ultraviolet radiation (or visible light) by the solute as it passes through the flow-cell. Absorption changes are proportional to concentration following the Beer-Lambert Law. Flow-cells generally have path-lengths of 5 to 10 mm with volumes between 5 and 10 μ l. These detectors give good sensitivities with many compounds, are not affected by slight fluctuations in flow rate and temperature, and are nondestructive, thus allowing solutes to be collected.

The simplest detectors are of the fixed-wavelength type and usually contain low-pressure mercury lamps which have an intense emission line at 254 nm. Some instruments offer conversion kits which allow the energy at 254 nm to excite a suitable phosphor to give a new detection wavelength (e.g. 280 nm). Variable-wavelength detectors have a deuterium lamp with a continuous emission from 180 to 400 nm and use a manually operated diffraction grating to select the required wavelength. Tungsten lamps (400-700 nm) are used for the visible region.

Many organic compounds absorb at 254 nm and hence a fixed-wavelength detector has many uses. However, a variable-wavelength detector can be invaluable to increase the sensitivity of detection

by using the wavelength of maximum absorption. This can also increase the selectivity of detection by enhancing the peak of interest relative to interfering peaks. Most drugs show some absorption at very low wavelengths (220 nm or less), but as selectivity is low such detection wavelengths should only be used to enhance sensitivity in the analysis of samples known to contain a particular drug (e.g. therapeutic drug monitoring).

Eluents must have sufficient transparency at the selected detection wavelength and Fig. 1 shows the absorption spectra of several solvents commonly employed. The spectra were recorded in 1-cm cells with water as the reference. These represent purified solvents; reagent grade solvents contain impurities which can limit their use to even longer wavelengths. Buffer salts can also limit transparency.

The spectra of some drugs change with pH and the sensitivity and selectivity of an assay can sometimes be controlled by changing the eluent pH. The influence of such changes on the chromatography must also be considered.

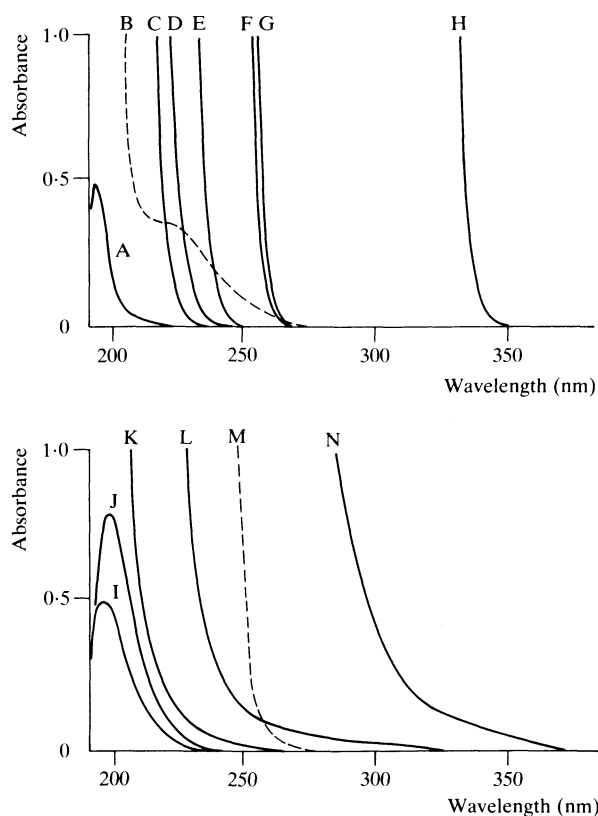

Fig. 1. Ultraviolet absorption of solvents (HPLC grade unless otherwise stated). A, acetonitrile (far-UV grade); B, methyl *tert*-butyl ether; C, acetonitrile; D, 1-chlorobutane; E, methylene chloride; F, acetic acid (AR grade); G, ethyl acetate; H, acetone; I, hexane; J, iso-octane; K, methanol; L, tetrahydrofuran; M, chloroform; N, diethylamine (AR grade).

FLUORESCENCE DETECTORS

In this detector, the solute is excited with ultraviolet radiation and emits radiation at a longer wavelength. Some detectors allow for selection of both excitation and emission wavelengths either by the insertion of appropriate filters or by the use of monochromators. There are only a few drugs which have strong natural fluorescence (e.g. ergot alkaloids), and for such drugs fluorescence detection can achieve better sensitivities than ultraviolet detection. However, many drugs can be converted into fluorescent derivatives. The selectivity of fluorescence detection can be extremely valuable for the identification of drugs since the excitation and emission information can be used in addition to the retention data (L. A. King, *J. Chromat.*, 1981, 208, 113-117).

Eluents chosen for fluorescence detection should not fluoresce nor should they absorb at the excitation or emission wavelengths used. The pH may also be important because some drugs only show fluorescence in particular ionic forms.

REFRACTIVE INDEX DETECTORS

These detectors respond to changes in refractive index (positive or negative) arising from the presence of a compound in the eluent. All the factors which can affect refractive index must be carefully controlled (e.g. temperature, eluent composition, pressure) otherwise noise and drift will limit the sensitivity. Thus the chromatograph is best placed in a thermostatically-controlled cabinet and good pumps are desirable to minimise pressure fluctuations. Changes in eluent composition will also cause spurious changes in refractive index.

The refractive index detector is inherently insensitive (as much as 100 times less sensitive than UV detectors) and this severely limits its use in drug analysis. However, it can be used when the compounds of interest do not have a suitable ultraviolet chromophore and are present in high concentration, e.g. sugars in drug preparations (B. B. Wheals and P. C. White, *J. Chromat.*, 1979, 176, 421-426).

ELECTROCHEMICAL DETECTORS

In this detector, solutes undergo electrolytic oxidation or reduction at the surface of an electrode, with measurement of the resulting current. Two

types of detector are available. The *coulometric detector* has a large electrode surface and the electrochemical reaction of each solute is taken to completion, while the *amperometric detector* has a small electrode with a low degree of conversion (typically < 10%). The larger current response of coulometric detectors would be expected to make them more sensitive than amperometric detectors but in practice the difference is very small (P. T. Kissinger, *Analyt. Chem.*, 1977, 49, 447A-456A). The major problem with electrochemical detection is the contamination of the electrode surface during operation. Various electrode materials have been used but glassy carbon finds widespread application. Flow-cells with a dropping mercury electrode have the advantage of avoiding contamination by continuous replacement of the electrode surface but they can only be used in the reduction mode.

Eluents for electrochemical detection must be electrically conductive, which is achieved by the addition of inert electrolytes at concentrations between 0.05 and 0.1M. Potassium nitrate is often used for aqueous eluents while tetra-alkylammonium perchlorates can be used for organic eluents. All solvents and buffers used in the preparation of an eluent must be pure, and chosen so that they do not undergo electrochemical changes at the applied potential.

Electrochemical detectors can be used in the oxidative mode for a wide range of drugs, including cannabinoids, haloperidol, morphine, paracetamol, phenothiazines, salicylic acid, and tricyclic antidepressants. Operation in the reductive mode is more difficult as dissolved oxygen must be removed from the eluent (K. Bratin *et al.*, *J. liq. Chromat.*, 1981, 4, 1777-1795). Reductive applications include chloramphenicol and benzodiazepines.

MISCELLANEOUS DETECTORS

Other detection principles have been applied to HPLC, e.g. conductivity, radioactivity, infra-red, and photoconductivity detectors. Such detectors are not widely used in drug analysis but can find application in special circumstances (e.g. the identification of drug metabolites arising from a radiolabelled drug by radioactivity detection).

Practical Aspects of HPLC Theory

The practical application of HPLC is aided by an awareness of the concepts of chromatographic theory, in particular the measurement of chromatographic retention and the factors which influence resolution.

CHROMATOGRAPHIC RETENTION

The retention of a drug with a given packing material and eluent can be expressed as a retention time or retention volume but both of these are dependent on flow rate, column length, and column diameter. The retention is best described as a column capacity ratio (k') which is independent of these factors. The column capacity ratio of a compound (A) is defined by

$$k'_A = \frac{V_A - V_0}{V_0} = \frac{t_A - t_0}{t_0}$$

where V_A is the elution volume of A and V_0 is the elution volume of a non-retained compound (i.e. void volume). At constant flow rate, retention times (t_A and t_0) can be used instead of retention volumes. The injection of a solvent or salt solution can be used to measure V_0 , but the solute used should always be recorded along with reported k' data. The importance of selecting suitable solutes for the measurement of V_0 has been discussed (M. J. M. Wells and C. R. Dark, *Analyt. Chem.*, 1981, 53, 1341-1345).

It is sometimes convenient to express retention data relative to a known internal standard (B). The ratio of retention times (t_A/t_0) can be used, but the ratio of adjusted retention times ($(t_A - t_0)/(t_B - t_0)$) is better when wishing to transfer data between different chromatographs (L. S. Ettre, *J. Chromat.*, 1980, 198, 229-234).

EVALUATION OF CHROMATOGRAPHIC PERFORMANCE

For information on the evaluation of the performance of chromatographic columns, see under Gas Chromatography, p. 189.

Stationary Phases and Eluents

The systems used are often described as belonging to one of four mechanistic types, adsorption, partition, ion-exchange, and size exclusion. *Adsorption chromatography* arises from interactions between solutes and the surface of the solid stationary phase. Generally, the eluents used for adsorption chromatography are less polar than the stationary phases and such systems are described as 'normal-phase'. *Partition chromatography* involves a liquid stationary phase which is immiscible with the eluent and coated on an inert support. Partition systems can be normal-phase (stationary phase more polar than eluent) or reversed-phase (stationary phase less polar than eluent). *Ion-exchange chromatography* involves a solid stationary phase with anionic or

cationic groups on the surface to which solute molecules of opposite charge are attracted. *Size-exclusion chromatography* involves a solid stationary phase with controlled pore size. Solutes are separated according to their molecular size, the large molecules unable to enter the pores eluting first. However, this concept of four separation modes is an over-simplification. In reality there are no distinct boundaries and several different mechanisms often operate simultaneously.

COLUMN PACKING MATERIALS

The most widely used materials are rigid, totally porous particles with diameters in the range 3 to 10 μl . These allow rapid diffusion of solutes between the mobile and stationary phases and give columns of good efficiency with back pressures within the capabilities of modern HPLC pumps. Spherical particles are preferred as these give lower back pressures. It is particularly important that very small particles (fines) are not present as these can block meshes and tubing.

Silica-based Packing Materials

Silica ($\text{SiO}_2 \cdot x\text{H}_2\text{O}$) is the most widely used substance for the manufacture of packing materials. It consists of a network of siloxane linkages ($\text{Si}-\text{O}-\text{Si}$) in a rigid three-dimensional structure containing interconnecting pores. The size of the pores and the concentration of silanol groups ($\text{Si}-\text{OH}$) which line the pores can be controlled in the manufacturing process. Thus a wide range of commercial products is available with surface areas ranging from 100 to 800 m^2/g and average pore sizes from 4 to 33 nm. The silanol groups on the surface of silica give it a polar character which is exploited in adsorption chromatography using organic eluents. Silanol groups are also slightly acidic and hence basic compounds are particularly strongly adsorbed. Unmodified silicas can thus be used with aqueous eluents for the chromatography of basic drugs.

Silica can be drastically altered by reaction with organochlorosilanes or organoalkoxysilanes giving $\text{Si}-\text{O}-\text{Si}-\text{R}$ linkages with the surface. The attachment of hydrocarbon chains to silica produces a non-polar surface suitable for reversed-phase chromatography where mixtures of water and organic solvents are used as eluents. The most popular material is octadecyl-silica (ODS-silica) which contains C_{18} chains, but materials with C_2 , C_6 , C_8 , and C_{22} chains are also available.

During manufacture such materials may be reacted with a small monofunctional silane (e.g. trimethylchlorosilane) to reduce further the number

of silanol groups remaining on the surface (end-capping). Variations in elution order on different commercial packing materials of the same type (e.g. ODS-silica) are often attributed to differences in surface coverage and the presence of residual silanol groups. There is a vast range of materials which have intermediate surface polarities arising from the bonding to silica of other organic compounds which contain groups such as phenyl, cyano, nitro, amino, and hydroxyl. Strong ion-exchangers are also available in which sulphonic acid groups or quaternary ammonium groups are bonded to silica. For size-exclusion chromatography, a special type of silica is available which has a narrow range of pore diameters. Size-exclusion chromatography can be complicated by adsorption but this can be reduced by treating the surface with trimethyl-chlorosilane. The useful pH range for columns is 2 to 8 since siloxane linkages are cleaved below pH 2 while at pH values above 8 silica may dissolve. However, the pH range may be extended above 8 if a precolumn packed with microparticulate silica is included between pump and injector to saturate the eluent before it enters the analytical column.

Polymer-based Packing Materials

Several packing materials are available which are based on organic polymers. For example, unmodified styrene-divinylbenzene copolymers have a hydrophobic character and can be used for reversed-phase chromatography. Although they can give lower column efficiencies than ODS-silica they have the advantage of being stable over a wide pH range. They also avoid problems associated with residual silanol groups (e.g. peak tailing). Ion-exchange materials of the styrene-divinylbenzene type are also available in which sulphonic acids, carboxylic acids, or quaternary ammonium groups are incorporated in the polymeric matrix.

PACKING THE COLUMN

Column packing is very straightforward provided that a packing pump, slurry reservoir, and ultrasonic bath are available. Such equipment rapidly pays for itself as prepacked columns are very expensive. High flow rates and high pressures (up to 10 000 lb/in^2 , 69MPa) are required and pneumatic amplifier pumps are most suitable. A multiple switch valve should be fitted to the solvent inlet line and connected to a series of solvent containers so that solvent changes can be made rapidly without stopping the pump.

The pump outlet is connected to the slurry reservoir which in turn is connected to the empty column. This last union should be made with a connector having an internal diameter comparable to that of the column. The slurry reservoir should have a capacity of 30 to 40 ml for packing analytical columns and must obviously be capable of withstanding the packing pressures.

The following procedures are recommended for packing silica and ODS-silica into 100× 5 mm internal diameter columns.

Silica. Clean an empty column and fit it with a stainless steel mesh disk at the outlet end. Prime the pump with methanol and set it to deliver a pressure of 7500 lb/in² (52 MPa). Clamp the slurry reservoir in a vertical position with the bottom connected to the pump outlet. Weigh 1.8 g of silica into a glass-stoppered flask (50 ml) and add 30 ml of methanol. Shake vigorously until a homogeneous suspension is produced and then place the flask in an ultrasonic bath for 5 minutes. Pour the slurry into the reservoir, connect the empty column to the reservoir (outlet upwards), and switch on the pump. These manipulations must be conducted as rapidly as possible. Allow 100 ml of solvent to pass through the column then invert the whole column-reservoir assembly so that the top of the column is upwards. Pump a further 50 ml of methanol through the column then switch off the pump and allow the pressure to subside (10 minutes). Disconnect the column from the reservoir, remove excess packing material, and fit a stainless steel mesh and end fitting. For normal-phase chromatography, the column must be activated by passing through it a series of solvents with decreasing polarity, finally using dry hexane.

ODS-Silica. The general procedure is similar to that described above. Suspend 1.8 g of ODS-silica in 30 ml of isopropyl alcohol and pack the column in an upward direction using hexane as the pressurising solvent. Allow 100 ml of solvent to pass, then invert the assembly and pass a further 50 ml. Pump 50 ml of methanol through the column followed by 75 ml of a 50:50 (v/v) mixture of methanol and water. Remove the column from the reservoir as above.

All new columns should be tested to check the success of the packing. The test can then be repeated at a later date to monitor the performance of the column with use. If the column has been packed for a particular assay involving the separation of a group of drugs, these compounds can be used as the test mixture. Alternatively, a standard test mixture can be used (P. A. Bristow and J. H. Knox, *Chromatographia*, 1977, 10, 279-289).

SYSTEMS FOR DRUG ANALYSIS

A large number of eluent/packing material combinations have been used for drug analysis. However, most drug analyses are currently performed on silica or one of the hydrocarbon-bonded silicas (usually ODS-silica). Other types of packing are only employed when these conventional materials fail. The majority of drug analyses can be carried out with the following four types of system.

Silica with Non-polar Eluents

Here the principal mechanism is adsorption chromatography. Separation is controlled by the competition between solute molecules and molecules of the mobile phase for the adsorption sites on the silica surface. Polar groups are most strongly attracted to these sites and hence polar compounds are more strongly retained than non-polar ones. Retention can be decreased by increasing the polarity of the eluent.

Adsorption energies of numerous solvents on alumina (ϵ° values, see below) have been measured and this scale can be used as a good guide to the elution strengths of eluents on silica as well as alumina (L. R. Snyder, *Principles of Adsorption Chromatography*, New York, Marcel Dekker, 1968, pp.194-195).

Pentane	0.00	Acetone	0.56
Hexane	0.01	Ethyl acetate	0.58
Iso-octane	0.01	Diethylamine	0.63
Cyclohexane	0.04	Acetonitrile	0.65
Toluene	0.29	Isopropyl alcohol	0.82
1-Chlorobutane	0.30	Ethanol	0.88
Ether	0.38	Methanol	0.95
Chloroform	0.40	Acetic acid	large
Methylene chloride	0.42	Water	large
Tetrahydrofuran	0.45		

Mixtures of solvents can be employed giving elution strengths in between those of the pure solvents. Furthermore, different solvent mixtures having the same ϵ° value will often give different separations of a group of compounds.

Water is strongly bound to silica and thus the water content of the eluent must be strictly controlled to maintain constant activity of the silica surface and hence reproducible retention times. This is most critical when the eluent is of very low polarity. However, because anhydrous systems are difficult to maintain, a low concentration of water can be used in the eluent, sufficient to deactivate the most active sites without deactivating the whole surface.

Typical water concentrations range from 0.01 to 0.2% v/v. The most satisfactory method of preparing a solvent of known water content is to mix anhydrous and water-saturated solvent in known proportions. Anhydrous hydrocarbon or halo-hydro-carbon solvents can be prepared by passing them through a bed of activated silica or alumina (200 μm) in a glass column. Because of the problems associated with the control of water concentration, alcohols such as methanol (0.01 to 0.5% v/v) are commonly employed to moderate the silica surface (H. Engelhardt, *J. chromatogr. Sci.*, 1977, 15, 380-384).

Silica with Polar Eluents

Several systems have been described which involve the use of silica with eluents of moderate to high polarity containing alcohols and/or water as major components. With such eluents, adsorption chromatography is most probably not the principal mechanism. The mechanisms are poorly understood, making the prediction of retention behaviour difficult; nevertheless, many of these systems are very useful for drug analysis.

An eluent consisting of methanol: ammonium nitrate buffer (90:10) (see System HC) is suitable for a wide range of basic drugs (e.g. amphetamines and opiates—see Fig. 2). Retention can be controlled by changes to the pH, ionic strength, or methanol/water ratio, or by addition of other organic solvents such as methylene chloride. With these alkaline eluents the silica surface must bear a negative charge and the principal mechanism is probably cation-exchange.

Fig. 2. Separation of some basic drugs using System HC. A, phendimetrazine; B, phenylpropanolamine; C, phentermine; D, amphetamine; E, morphine; F, ephedrine; G, methylamphetamine.

Benzodiazepines can be chromatographed with methanolic eluents containing perchloric acid (typically 0.001 M). Retention can be modified by the addition of other organic solvents (e.g. ether) or by changes to the acid concentration.

Both acidic and basic drugs can be chromatographed on silica using aqueous methanolic eluents containing cetyltrimethylammonium bromide (S. H. Hansen, *J. Chromat.*, 1981, 209, 203-210). Hydrophobic quaternary ammonium ions are strongly adsorbed on silica giving a dynamically coated stationary phase. Retention may be controlled by varying the concentration or nature of the quaternary ammonium ion, changing the ionic strength or pH of the buffer, or changing the concentration or nature of the organic component.

ODS-Silica with Polar Eluents

Eluents for reversed-phase chromatography on ODS-silica are usually mixtures of methanol or acetonitrile with an aqueous buffer solution. Retention is mainly controlled by the hydrophobic interactions between the drugs and the alkyl chains on the packing material. Retention increases as the solutes decrease in polarity, i.e. polar species are eluted first (Fig. 3). Hence, elution time is increased by increasing the polarity of the eluent (i.e. increasing the water content). The pH of the eluent and the pK_a of the drug are also important since it is the non-ionised species that shows greater retention. Thus, acids show an increase in retention as the pH is reduced while bases show a decrease. It is important to use a buffer of sufficient capacity to cope with any injected sample size otherwise tailing peaks can arise from

Fig. 3. Separation of some benzodiazepines using System HI. A, clorazepic acid; B, nitrazepam; C, clobazam; D, oxazepam; E, temazepam; F, chlordiazepoxide; G, diazepam; H, ketazolam.

changes in ionic form during chromatography. Phosphate buffers (0.05 to 0.2M) are widely used as they have a good pH range and low ultraviolet absorbance.

Drugs containing basic nitrogen atoms sometimes show poor efficiencies and give tailing peaks due to interactions with residual silanol groups on the packing material. This can often be improved by the addition of an amine or quaternary ammonium compound to the eluent which competes with the solutes for adsorption sites on the silica. Amines of small molecular weight (e.g. diethylamine) can be used as part of the buffer system. Alternatively, low concentrations (0.001 M perhaps) of long-chain hydrophobic modifiers (e.g. *NN*-dimethyloctylamine) can be added to eluents together with conventional buffers.

Other hydrocarbon-bonded packing materials can be used in reversed-phase chromatography. A decrease in retention is associated with a decrease in the alkyl chain length.

ODS-Silica with Polar Eluents containing Hydrophobic Cations or Anions Drugs bearing positive or negative charges are poorly retained in reversed-phase systems. If the pH of the eluent cannot be changed to convert the drug to its non-ionised form, a hydrophobic ion of opposite charge can be added to form a neutral ion pair and increase retention. Hence, for a basic drug an acidic eluent is chosen and a hydrophobic anion added. This technique is referred to as reversed-phase ion-pair chromatography.

The sodium salts of alkylsulphonic acids ($\text{RSO}_3^- \text{Na}^+$ where R=pentyl, hexyl, heptyl, or octyl) are widely used as ion-pair reagents for basic drugs, while quaternary ammonium compounds (e.g. tetrabutylammonium salts) are used for acidic drugs. Ion-pair reagents are generally added to eluents in the concentration range 0.001 to 0.005 M and within this range an increase in concentration leads to an increase in retention. When detergents such as sodium lauryl sulphate or cetyltrimethylammonium bromide are used as the ion-pair reagents, the method is sometimes referred to as 'soap chromatography'. With these salts, ions build up on the surface of the packing material and produce a stationary phase which behaves like an ion-exchanger. This type of mechanism has been described as 'dynamic ion-exchange' and probably also occurs with less hydrophobic ion-pair reagents. It is virtually impossible to remove completely an ion-pair reagent from a hydrocarbon-bonded phase and such columns

should not therefore be reused with other reversed-phase eluents.

SELECTION OF CHROMATOGRAPHIC SYSTEMS

There may be many different combinations of packing material and eluent which are suitable for the analysis of a particular compound or group of compounds, and the final choice can be influenced by many factors. The time required for development of a new system can be shortened if it is possible to predict the way in which changes in eluent composition will influence chromatographic retention. Systems using hydrocarbon-bonded phases are particularly attractive from this viewpoint as a large range of parameters can be adjusted (pH, organic solvent, ionic strength, ion-pair reagents) with largely foreseeable consequences. Predictions for silica are generally less reliable. Silica is good for separating drugs belonging to different chemical classes, while hydrocarbon-bonded silicas are preferred for separations of drugs with closely related structures, e.g. barbiturates.

Most of the endogenous material in biological extracts which can interfere with the analysis of a drug is fairly polar. In reversed-phase systems this material generally elutes before the drug and can obscure the drug peak. In these circumstances, reversed-phase ion-pair chromatography can be valuable to increase selectively the retention of the drug relative to the interfering peaks. Normal-phase systems using silica do not generally suffer from this problem as most of the endogenous material usually elutes after the drug. However, these slow eluting compounds can lead to a noisy baseline or may remain adsorbed to the packing material and thus eventually lead to a loss in column performance.

Quantitative Analysis

The methods of quantitative analysis are essentially those inherited from gas chromatography. Peak height or peak area can be measured, either manually or with electronic devices. Peak height measurements have the advantage of simplicity but are sensitive to changes in peak shape; peak area measurements should always be used where peaks are broad and tailing.

For a given system, a calibration graph must be constructed for each compound to be analysed because the detector response to each will be different. This graph of peak height (or area) against drug concentration can then be used to quantify the unknown sample. Such external calibration requires

careful control of injection volumes, and valve injection should be used. However, external calibration is still susceptible to errors arising from fluctuations in column performance, and the internal standard technique gives better precision. This involves the addition of a fixed amount of a substance (internal standard) to the sample before injection. Quantification is carried out using peak height (or area) ratios of drug to internal standard. In this case, calibration graphs are prepared by injecting solutions containing known amounts of drug together with the same fixed quantity of internal standard. For the analysis of drugs in complex samples, the internal standard should be added to the mixture before extraction to compensate for extraction losses.

Eluent Preparation

The quality of solvents and inorganic salts is an important consideration. Soluble impurities can give noisy baselines and spurious peaks or can build up on the surface of the packing material, eventually changing chromatographic retentions. Furthermore, the eluate may need to be collected for further analysis (e.g. mass spectrometry) and all contamination must be avoided. In addition, particulate matter should be removed, otherwise pump filters, meshes, and tubing can become blocked.

A wide range of HPLC-grade solvents is now commercially available which are free from particulate matter, have low residues on evaporation, and have guaranteed upper limits of ultraviolet-absorbing and fluorescent impurities. However, if a detector is not to be operated at its maximum sensitivity, analytical grade solvents may be used. Acetonitrile is a particularly difficult solvent to purify and two grades are generally offered; the purer grade is essential for ultraviolet detection at wavelengths around 200 nm. Water should be distilled from glass and should not be stored in plastic containers, which can cause organic contamination. Air dissolved in the mobile phase can lead to problems. The formation of a bubble in a pump head usually reduces or stops eluent flow, while bubbles formed in the detector can give spurious peaks. The remedy is to degas the eluent by refluxing or by applying a weak vacuum to the eluent in a container placed in an ultrasonic bath. Eluents can also be degassed by purging with helium which has a very low solubility and drives the air out. Care must always be taken when degassing eluents containing

volatile components to avoid changing the composition. It is convenient to prepare eluents as volume plus volume mixtures of solvents, i.e. the volume of each solvent is measured separately and then mixed. Volume changes can occur when solvents are mixed (e.g. methanol and water show a contraction) and this must be remembered if the volume of only one solvent is measured and the second solvent added to make up to volume (v/v). True pH values can only be measured in aqueous solutions and any measurements made with a pH meter in aqueous-organic solvents should be described as 'apparent pH'. In general, the apparent pH of a buffer solution rises as the proportion of organic solvent in the aqueous mixture increases. When preparing an eluent it is usually best to dissolve the required buffer salts in water at the appropriate concentrations, adjust the pH, then mix this solution (v/v) with the organic solvents.

Column Maintenance

The life of a column can be considerably extended if a few basic precautions are taken. The importance of choosing non-corrosive eluents (e.g. suitable pH values for silica packing materials) and the use of solvents and salts of high purity have already been discussed. In addition, a column should not be subjected to rapid changes in pressure or to flow rates outside of the normal operating range. Eluents can sometimes be left in the column overnight, but aqueous eluents containing inorganic salts should always be removed to prevent crystallisation, bacterial growth, or corrosion. For long-term storage the column must be thoroughly washed with suitable solvents and the ends tightly capped keeping the column wet to prevent the packing bed from cracking. Aqueous methanol (50% v/v) can be used to store ODS-silica columns, while methanol or hexane can be used for silica columns. Columns should be stored at room temperature away from physical disturbance.

A repeat of the test procedure normally applied to a column immediately after packing can quickly reveal any changes in performance. An increase in back pressure probably indicates that the top mesh or the top of the packing bed is blocked with particulate matter. Changes in the chromatographic retention of the test compounds suggest that the column has been contaminated with impurities adsorbed on the packing material. It is sometimes possible to remove such impurities by making large injections (1 ml perhaps) of a solvent with high elution strength.

The cleaning of hydrocarbon-bonded silicas should always include a wash with dilute acid (0.1M sulphuric acid), which is effective in removing impurities from residual silanol groups.

If washing fails to restore a column, the contaminated packing material at the top of the column should be replaced. This procedure should also be applied if the packing bed has sunk, leaving a void. Such voids generally manifest themselves by a drop in efficiency, poor peak shape, or even the appearance of two peaks for a single compound. The column should be clamped vertically and the visibly contaminated packing material removed. A perfectly level surface must be left on the top of the packing bed. The space is filled with a thick paste of the packing material in methanol. Once the column has been pressurised on a pump it is sometimes necessary to top up with packing material again. Successful repacking to a depth of about 10 mm is feasible.

Sample Injection

Ideally, samples should be dissolved in the eluent prior to injection. However, if the sample has low solubility, it is sometimes necessary to use a more powerful solvent and in such cases only small injection volumes should be used otherwise broad peaks with shoulders can arise. Injection solvents of lower elution strength than the eluent can be useful for dilute samples, as the material concentrates on the top of the column during the injection. Nevertheless, large injections of any liquid other than eluent can cause serious detector disturbances.

Special Techniques

GRADIENT ELUTION

HPLC can be performed with a single eluent (isocratic elution) or with changes in composition (gradient elution). The elution strength of the eluent is increased during the gradient run by changing polarity, pH, or ionic strength. Gradient elution can be a powerful tool for separating mixtures of compounds with widely differing retention. A direct comparison can be drawn with temperature programming in gas chromatography.

Eluent gradients are usually generated by combining the pressurised flows from two pumps and changing their individual flow rates with an electronic programmer while maintaining the overall flow rate constant. Alternatively, a single pump with a low sweep volume can be used in combination with a gradient generator which controls the ratio

of two liquids entering the pump from two liquid reservoirs. Equipment is available which allows the gradient to take almost any conceivable form including a reverse gradient to return the system to the original eluent.

Gradient elution does have several drawbacks. The extra equipment is usually very costly and the technique can be very time-consuming as the column must be reconditioned with the initial eluent between runs. In addition, drifting of the detector response and the appearance of spurious peaks arising from solvent impurities may occur. Although gradient elution should be avoided wherever possible it may be necessary for the analysis of complex mixtures where the components have wide-ranging polarities.

DERIVATIVE FORMATION

Derivatisation of a drug is seldom necessary to achieve satisfactory chromatography. This applies for compounds of all polarities and molecular weights and is an important advantage of HPLC over gas chromatography. Derivatisation is used to enhance the sensitivity and selectivity of detection when available detectors are not satisfactory for the underivatised compounds. Both ultraviolet-absorbing and fluorescent derivatives have been widely used. Ultraviolet derivatisation reagents include *N*-succinimidyl *p*-nitrophenylacetate (SNPA), phenylhydrazine, and 3,5-dinitrobenzoyl chloride (DNBC), while fluorescent derivatives can be formed with reagents such as dansyl chloride (DNS-Cl), 4-bromomethyl-7-methoxycoumarin (BMC), and fluorescamine.

Derivative formation can be carried out before the sample is injected on to the column (pre-column) or by on-line chemical reactions between the column outlet and the detector. Such post-column reactions generally involve the addition of reagents to the eluent. With pre-column derivatisation there are no restrictions on reaction conditions (e.g. solvent, temperature) and a large excess of reagent can be used, as this can be separated from the derivatives during the chromatography. The major drawback of pre-column reactions is the need to obtain reproducible yields for accurate quantification, and this is best achieved when the reactions proceed to completion. Furthermore, it is important that the products of pre-column derivatisation reactions are fully characterised. With post-column derivatisation the reaction is well controlled by the flow rates of eluate and reagents, temperature, etc. Hence, it is not necessary for the reaction to proceed to

completion or even for the chemistry to be understood as the system is calibrated by the injection of known quantities of the reference standards.

The techniques and applications of derivatisation for drug analysis have been reviewed: J. F. Lawrence and R. W. Frei, *Chemical Derivatization in Liquid Chromatography*, Amsterdam, Elsevier, 1976; R. W. Frei, *J. Chromat.*, 1979, 165, 75-86; S. Ahuja, *J. chromatogr. Sci.*, 1979, 77, 168-172; R. W. Frei and J. F. Lawrence, *Chemical Derivatization in Analytical Chemistry*, New York, Plenum Press, Vol. 1, 1981; Vol. 2, 1982.

DETECTION BY IMMUNOASSAY

Immunoassay techniques (see p. 148) can often be very useful for off-line detection. This involves the collection of the eluate in small fractions (1 ml perhaps) and the performance of a drug assay on each fraction. A chromatogram is then constructed by plotting the assay results against the fraction numbers. Such detection methods are clearly time-consuming but often achieve sensitivities and selectivities much higher than conventional detectors. In many cases biological fluids can be injected directly on to the column.

HPLC with immunoassay detection is useful for the analysis of those metabolites which are difficult to isolate from biological fluids by extraction (e.g. glucuronides). Such polar compounds cannot be observed at low concentrations with conventional detectors as they are obscured by endogenous compounds. HPLC with immunoassay detection can be applied to the determination of cannabin-oids, opiates, lysergide, and cardiac glycosides in biological fluids (A. C. Moffat, *Analyt. Proc.*, 1981, 18, 115-116).

MULTIWAVELENGTH ULTRAVIOLET-VISIBLE DETECTION

It is clearly useful to obtain structural information about the compounds eluting from a column to aid the identification of unknown peaks. For ultraviolet-visible detection this can involve the use of two detectors in series to give a ratio of absorbances at two wavelengths. Alternatively, full absorption spectra may be obtained. The simplest method involves collecting the eluate corresponding to each peak and transferring this to a scanning spectrophotometer. Alternatively, the eluent flow can be stopped as each peak passes through the flow-cell of a variable-wavelength detector, and the spectrum constructed either by recording the absorbance at known wavelength intervals (e.g. 10 nm) or by the

use of equipment with automatic wavelength scan facilities.

These methods of obtaining complete ultraviolet-visible spectra can be very time-consuming. However, rapid scanning spectrophotometers based on optical diode array detectors are now commercially available and are capable of recording complete spectra in very short time intervals (1 second or less). They can therefore be used to obtain spectra of separated components without stopping eluent flow or to detect at several wavelengths simultaneously.

DETECTION BY MASS SPECTROMETRY

The use of a mass spectrometer as a detector (HPLC-MS) can provide much information concerning the structures of the compounds being separated. Interfaces are available (see under Mass Spectrometry, p. 253).

Applications

HPLC complements rather than supplants paper, thin-layer, and gas chromatography. Paper and thin-layer chromatography require only relatively simple and cheap apparatus and are particularly useful as general screening methods, as an unknown compound must appear somewhere between the origin and the solvent front after development. In contrast, a compound may fail to elute at all in gas chromatography or HPLC. Nevertheless, paper and thin-layer chromatography can rarely compete with the high resolution, sensitivity, and ease of quantification of HPLC and gas chromatography; the latter is the method of choice for compounds which are very volatile (e.g. anaesthetic gases, organic solvents, and alcohol) but is less suitable for compounds of low volatility arising from large molecular weight (e.g. insulin) or the presence of polar functional groups (e.g. quaternary ammonium drugs, drug metabolites, and conjugates). It is also unsuitable for thermally unstable compounds. In these cases HPLC is clearly the method of choice. Between these extremes are a large number of drugs where satisfactory analyses can be performed by gas chromatography or HPLC and the choice of method depends on the availability of suitable equipment (e.g. detectors) and the ability to separate the compounds of interest. An important difference between HPLC and gas chromatography concerns the methods by which retention and resolution may be controlled. In gas chromatography only stationary phase and temperature have any

significant effect, while in HPLC the composition of the mobile phase can also be altered with dramatic effects. The extra flexibility in HPLC can be extremely important, enabling difficult separations to be achieved. This enables a member of a particular drug group to be readily identified, but makes general screening for drugs difficult because there is no universal elution system, universal detector, or unified retention scale. Gas chromatography has these in the form of low polarity stationary phases, the flame ionisation detector, and the retention index scale, respectively. Hence, the major role of HPLC in drug analysis is the identification and quantification of specific drugs and poisons in body fluids and tissues or in pharmaceutical preparations.

ANALYSIS OF DRUGS IN PREPARATIONS

HPLC has found widespread use for the quantitative analysis of drugs in preparations of pharmaceutical and illicit manufacture. Drug concentrations are generally high enough to allow dissolution of the sample (tablet, powder, ointment, etc.) in a suitable solvent followed by injection. Ultraviolet-visible, fluorescence, or refractive index detection is normally used.

Within the pharmaceutical industry, HPLC is used at various stages of drug development, e.g. the optimisation of synthetic reactions and stability testing. Furthermore, it is extensively used for quality control during production to monitor the purity of drugs and excipients. HPLC systems can easily be automated (including injection and data handling), allowing large numbers of samples to be analysed rapidly and economically. HPLC is particularly valuable for the analysis of drugs which are polar (e.g. aspirin), thermally unstable (e.g. benzodiazepines), or are present in oil-based formulations where analysis by gas chromatography can be very difficult. Similarly, HPLC can be used for the forensic analysis of illicit preparations to aid the identification of an unknown drug by the measurement of retention times. Furthermore, as the technique is non-destructive, the eluted compounds can be collected for further analysis. HPLC can also be applied to natural materials such as cannabis resin and opium which contain numerous components and give complex chromatograms (Fig. 4). Although not all peaks may be identified, comparison of these 'fingerprint-patterns' can indicate whether two samples have a common origin. A similar approach may be applied to semi-synthetic materials such as

Fig. 4. Chromatogram of cannabis resin using System HL. Resin extracted with methanol:chloroform (4:1). A, cannabidiolic acid; B, cannabinol; C, Δ^9 -tetrahydrocannabinol; D, Δ^9 -tetrahydrocannabinolic acid.

illicit diamorphine which may also contain added components (e.g. caffeine, strychnine, or procaine).

ANALYSIS OF DRUGS IN BIOLOGICAL FLUIDS AND TISSUES

Several factors determine the ability of HPLC to detect a drug amongst the endogenous compounds present in biological material. Clearly, selective detection of the drug relative to the endogenous material is advantageous. Also the stationary phase and/or mobile phase can be altered to separate the drug peak from interfering peaks (e.g. using ion-pair reagents). Finally, the sample may be extracted before HPLC to concentrate the drug relative to the endogenous material.

The chromatographic system and detector should always be chosen to minimise the time needed for sample preparation. The complexity of the sample preparation procedure is controlled by several factors including the nature of the sample (urine, blood, liver, etc.), the condition of the sample, and the concentration of the drug. Interference from endogenous compounds is most acute when drug concentrations are low (e.g. therapeutic drug monitoring), and extensive sample preparation is often required. Such assays can be very susceptible to changes in the condition of the sample (e.g. a method developed for fresh blood may not be satisfactory for haemolysed samples) and this can present severe difficulties in forensic toxicology.

Thus, methods must be tested with the most difficult samples that may be encountered. In contrast, the analysis of biological samples containing high drug concentrations (e.g. fatal drug overdose) by HPLC generally requires much less sample preparation and is less susceptible to changes in sample condition. Sample preparation for HPLC is essentially the same as for other methods of drug analysis. A drug which is physically trapped within solid tissue (e.g. liver), or chemically bound to the surface of proteins, must be released; then the protein is precipitated to leave the drug in aqueous solution. The protein may be degraded by strong acids or enzymes, precipitated by various chemicals (e.g. tungstic acid, ammonium sulphate), or removed by ultrafiltration. Some drugs are destroyed by protein degradation methods while ultrafiltration and precipitation can lead to drug losses through protein binding. No single procedure works well for all drugs and the method should be selected to give maximum recovery of the drug being analysed.

When drug concentrations are high (typically $\mu\text{g/ml}$) and systems with polar mobile phases are used, the direct injection of deproteinised solutions may be acceptable. Proteins must be removed to protect the column from irreversible contamination. A rapid procedure is to mix the biological fluid with at least two volumes of methanol or acetonitrile, centrifuge to remove the precipitated protein, and inject the supernatant liquid. Urine can be similarly treated to guard against the precipitation of salts on the column. It is good policy to use a guard column between the injector and analytical column. This is packed with the same material as the analytical column and replaced at frequent intervals. The ratio of guard-column volume to analytical-column volume should be around 1:20, which keeps band broadening to a minimum while providing sufficient capacity to retain impurities.

When drug concentrations in biological fluids are low and detectors of high selectivity are not available, extraction procedures are generally required. Solvent extraction remains the most popular approach, as many factors can be modified to optimise the extraction. These modifications include changing the polarity of the organic solvent, the pH and ionic strength of the aqueous phase, and the use of ion-pairing agents. The organic extract may be directly injected on to the column, if it is miscible with the eluent, or evaporated to dryness and the residue dissolved in a suitable solvent before

injection. Care must be taken that volatile drugs are not lost by evaporation and that lipid material in the residue does not prevent the drug from dissolving in the new solvent.

Drugs can also be extracted by passing the biological fluid through short columns filled with solid adsorbents (e.g. XAD-resin, silica, ODS-silica). The column is washed with suitable solvents to remove endogenous material before the drug is removed by passing a solvent of higher elution strength. Such columns are usually attached to Luer lock syringes or suction devices to facilitate the passage of solvents. Extraction selectivity can be controlled by adjustments to the biological fluid before extraction (e.g. pH, ionic strength) and the choice of washing solvents. Although home-made columns can be used, disposable columns of this type can be purchased.

HPLC SYSTEMS FOR DRUG GROUPS

The following section contains a list of HPLC systems suitable for the chromatography of particular drug groups. The systems have been selected from the chromatographic literature and from systems used by the author, taking account of their suitability for routine applications.

The drugs are divided into chemical or pharmacological groups but some other drugs are included in certain groups if they are chemically similar and would be extracted with that group. In addition, a general screening system for basic drugs is included. The systems are not necessarily those which would be chosen for the quantitative analysis of any particular drug in a biological sample as such procedures require the consideration of other factors such as the method of detection, the type of biological material, the drug concentration, and the sample preparation technique. Nevertheless, the present systems can be used for biological fluid assays in many instances. References to specific HPLC methods for the quantification of drugs in biological samples are given in the individual drug monographs. Generally, reversed-phase systems using ODS-silica and silica systems using polar eluents have been chosen. Only two systems use materials other than silica or ODS-silica, which demonstrates their wide versatility.

Most chromatographic retention data are presented as k values; where data have been published as retention times, retention volumes, or relative retention times, these have been converted into k values with the aid of other information presented

in the publication or by experimental measurements.
NOTE. In the tables of k values, a dash indicates that no value is available for the compound, not that it does not elute.

BASIC NITROGENOUS DRUGS, GENERAL SCREEN

System HA

I. Jane *et al.*, *J. Chromat.*, 1985, 323, 191-225.
COLUMN. Silica (Spherisorb S5W, 5 μ m, 12.5 cm x 4.9 mm internal diameter).

ELUENT. A solution containing 1.175 g (0.01 M) of ammonium perchlorate in 1000ml of methanol; adjust to pH 6.7 by the addition of 1 ml of 0.1 M sodium hydroxide in methanol.

k' VALUES. Values for drugs in this system will be found in drug monographs and in the indexes to Analytical Data in Part 3; they are also included in the systems for specific groups of drugs which follow.

AMPHETAMINES, OTHER STIMULANTS, AND ANORECTICS

System HA, previously described, may be used, or Systems HB or HC, below.

System HB

R. GmetaL, *J. Chromat.*, 1981, 218, 639-646.
COLUMN. ODS-silica (ODS-Hypersil, 5 μ m, 25 cm x 5 mm internal diameter).

ELUENT. A solution confining 19.60 g (0.2M) of phosphoric acid and 7.314 g (0.1M) of diethylamine in 1000 ml of a 10% v/v solution of methanol; adjust the pH to 3.15 by the addition of sodium hydroxide solution.

System HC

B. Law *et al.*, *J. Chromat.*, 1984, 301, 165-172.
COLUMN. Silica (Spherisorb, 5 μ m, 25 cm x 5 mm internal diameter).

ELUENT. Methanol: ammonium nitrate buffer solution (90:10). To prepare the buffer solution add 94ml of strong ammonia solution and 21.5ml of nitric acid to 884 ml of water and adjust to pH 10 by the addition of strong ammonia solution.

Ultraviolet, Visible, and Fluorescence Spectrophotometry

A. F. Fell

Analytical absorption spectroscopy in the ultraviolet and visible regions of the electromagnetic spectrum has been widely used in pharmaceutical and biomedical analysis for quantitative purposes and, with certain limitations, for the characterisation of drugs, impurities, metabolites, and related substances. By contrast, luminescence methods, and fluorescence spectroscopy in particular, have been less widely exploited, despite the undoubted advantages of greater specificity and sensitivity commonly observed for fluorescent species. However, the wider availability of spectrofluorimeters capable of presenting corrected excitation and emission spectra, coupled with the fact that reliable fluorogenic reactions now permit non-fluorescent species to be examined fluorimetrically, has led to a renaissance of interest in fluorimetric methods in biomedical analysis.

Ultraviolet and Visible Spectrophotometry

Molecular absorption in the ultraviolet (UV) and visible region arises from energy transitions involving the outer orbital or valency electrons. Spectra in liquid media are usually broad, relatively featureless bands, due to the large number of closely-spaced vibrational and rotational transitions. The fundamental band shape approximates Gaussian or log-normal Gaussian curves. Given the broad, overlapping profiles commonly encountered, the shape and precise location of individual bands are of limited usefulness in qualitative analysis. However, any fine structure detected in the spectra, coupled with solvent and pH effects, can be of diagnostic value. More informative spectra can be obtained for some volatile molecules of toxicological interest, such as benzene and polynuclear aromatic hydrocarbons; when examined in the vapour phase, vibrational and rotational fine structure can be readily seen superimposed on the broad spectral profiles. However, most drugs, metabolites, and

related compounds are relatively non-volatile; their spectra are necessarily observed in solution, or possibly in the solid phase by reflectance, or by compression to form a KBr disk, as used in infra-red spectrophotometry.

Ultraviolet and visible Spectrophotometry finds its primary application in quantitative analysis. The scope of absorption spectroscopy can be significantly extended by the use of colour reactions, often with a concomitant increase in sensitivity and/or selectivity. Such reactions are used to modify the spectrum of an absorbing molecule so that it can be detected in the visible region, well separated from other interfering components in the ultraviolet spectrum. Moreover, chemical modification can be used to transform an otherwise non-absorbing molecule to a stable derivative possessing significant absorption. Spectral selectivity can be further enhanced by a number of chemical or instrumental techniques including difference, higher-derivative, and dual-wavelength Spectrophotometry. Such methods, and certain graphical techniques such as the Morton-Stubbs method, can contribute in different ways to reducing the general problem of spectral interference in quantitative spectroscopy. Spectral interference can arise from so-called 'irrelevant' nonspecific absorption, and also from absorption by other materials and impurities which may be present. When interference arises specifically from the spectral overlap of two or more well-defined components, a number of methods can be applied to measure the individual concentrations. These methods include the Vierordt multi-wavelength technique, least squares deconvolution, and second or higher derivative Spectrophotometry, as discussed below. Spectral selectivity, and in some cases detection sensitivity, can be significantly enhanced by the various chemical and instrumental techniques outlined above. Such methods should of course be validated by applying the conventional analytical

criteria of accuracy (against a reference method), linearity, precision, and independence from interfering substances.

The scope of ultraviolet and visible spectrophotometry can be further extended when combined with a chromatographic separation step such as HPLC. The development of rapid-scanning detectors based on the linear photodiode array permits spectra to be acquired during the elution of peaks. Computer-aided manipulation of these spectra has led to new strategies for the examination of chromatographic peak homogeneity, based on classical techniques in spectroscopy. The use of microcomputers enables the development of archive retrieval methods for spectral characterisation (A. F. Fell *et al.*, *J. Chromat.*, 1984, 316, 423-440).

Nomenclature

In the ultraviolet and visible spectrum, the energy of protons associated with electronic transitions lies in the range 147 to 630 kJ/mol. This energy (ΔE) can be expressed in terms of the principal parameters that define electromagnetic radiation, i.e. frequency ν (Hz), wavelength λ (nm), and wave-number $\tilde{\nu}$ (cm^{-1})

$$\Delta E = h\nu = \frac{hc}{\lambda} = hc\tilde{\nu}$$

where h is Planck's constant, and c is the velocity of radiation *in vacuo*.

The positions of peaks are sometimes described in terms of wavenumber, which has the advantage of being a linear function of energy but this term is much more frequently used in infra-red spectrophotometry. The practical unit most often used in ultraviolet and visible spectrophotometry is wavelength, usually expressed in nanometres (nm). The older units of wavelength, millimicron ($\text{m}\mu$) and angstrom (\AA), are not recommended terms. The position of maximum absorbance of a peak is designated λ_{max} .

The wavelength span is conventionally divided into two ranges: the ultraviolet extends from 200 nm to about 400 nm; the visible range extends from about 400 nm to 800 nm. Outside these limits, the 'far ultraviolet' or 'vacuum ultraviolet' extends from 100 nm to 200 nm, and the 'near infra-red' from 1 μm to about 3 μm .

A molecular grouping which is specifically responsible for absorption is described as a chromophore, usually a conjugated system with extensive delocalisation of electron density. Any

saturated group which has little or no intrinsic absorption of its own, but which modifies the absorption spectrum when attached directly to a chromophore, is described as an auxochrome, examples being $-\text{OR}$, $-\text{NR}_2$, $-\text{SR}$. Auxochromes are considered to exert their effect through partial conjugation of their polarisable lone-pair electrons with those of the adjacent chromophore. If, however, the lone-pair of electrons is involved in bonding as, for example, in the case of a protonated quaternary ammonium group, the auxochromic effect vanishes. This property can be used for molecular characterisation, as discussed below.

Laws of Absorption

The extent of absorption of radiation by an absorbing system at a given monochromatic wavelength is described by the two classical laws of absorptiometry which relate the intensity of radiation incident on the absorbing system (I_0), to the transmitted intensity (I) (Fig. 1). Lambert's (or Bouguer's) Law concerns instrumental factors, and states that at a given concentration (c) of a homogeneous absorbing system, the transmitted intensity (I) decreases exponentially with increase in path-length (b). The complementary Beer's Law deals with concentration and states that for a layer of defined path-length (b) the transmitted intensity (I) decreases exponentially with increase in concentration (c) of a homogeneous absorbing system.

Fig. 1. Diagrammatic representation of energy relationships in absorption spectroscopy. I_0 , intensity of incident radiation; I , intensity of transmitted radiation; b , path-length; c , concentration of the absorbing species.

Combination of these observations gives the familiar Beer-Lambert Law

$$\log \frac{I_0}{I} = kcb$$

where k is the absorptivity of the system. The logarithmic term is linearly related to concentration and path-length and is referred to as absorbance (A). The older terms, extinction (E) and optical

density (OD) are not recommended although often found in the literature. Transmittance ($T=I/I_0$) and percentage transmittance [$\%T=100(I/I_0)$] are not linear functions of concentration and path-length and can be readily related to absorbance

$$A = \log \frac{I_0}{I} = \log \frac{1}{T} = 2 - \log (\%T)$$

The absorptivity (k) is a fundamental property of a molecule at a specified monochromatic wavelength. It has two connotations in European usage, and a third according to American convention. If the concentration is expressed in mol/litre, then k is described as the molar absorptivity (ϵ , litre/mol/cm), and defined as 'the absorbance of a one molar solution in a cell of 1 cm path-length'. It may also be quoted as the logarithm (base 10), the values being in the range 1 to 5.

When concentration is expressed in g/100 ml, k is described as the specific absorbance and given the symbol $A_1^{1\%}$ or $A(1\%, 1 \text{ cm})$, defined as 'the absorbance of a 1% w/v solution in a cell of 1 cm path-length'. It is usually written in the shortened form A_1^1 and is widely used in analytical chemistry. It was formerly known as the 'specific extinction coefficient', symbol $E_{cm}^{\%}$ or $E(1\%, 1 \text{ cm})$. American convention recognises the constant k as 'absorptivity' (a , litre/g/cm) defined as 'the absorbance of a 1 g/litre solution in a cell of 1 cm path-length'. These terms for absorptivity can be readily inter-converted, as follows

$$a = \frac{A_1^1}{10} = \frac{\epsilon}{\text{mol. wt}}$$

Thus a compound with a molecular weight of 100 whose absorptivity $a = 20$ at wavelength λ , in a particular solvent at a defined pH (if aqueous) and at a specified temperature, would have a corresponding specific absorbance $A_1^1 = 200$ and a molar absorptivity $\epsilon = 2000$.

Absorbance and absorptivity are often expressed in logarithmic form in cases where spectra are to be compared. The logarithmic form of the Beer-Lambert Law expresses the effects of absorptivity (k), -concentration (c), and path-length (b) as additive terms

$$\log A = \log k + \log c + \log b$$

Since only the absorptivity (k) is a function of λ , the

shape of a logarithmic absorption curve is independent of concentration and path-length. Their only effect is to shift the $\log A$ spectrum along the $\log A$ axis. A disadvantage of the $\log A$ plot is that fine structure near the top of the peak is compressed. The practical usefulness of specific absorbance values (A_1^1) clearly depends on a number of factors. These include the state of purity of the substance, the solvent conditions originally used to establish the reference data, the precise conditions employed in the reference instrument, and the extent to which they correspond with those of a particular test laboratory. It is therefore wise to ascertain the status of any absorptivity data in the literature. In the monographs in Part 2, the reliability of all A_1^1 values has been assessed and indicated (see General Notices). However, if a sample of the drug concerned is available in pure form, it is good practice to establish periodically a 'local' value of the absorptivity and to use this in calculating sample concentrations.

VALIDITY OF THE BEER-LAMBERT LAW

The validity of the Beer-Lambert Law is affected by a number of factors. If the radiation is non-monochromatic, i.e. its spectral bandwidth is greater than about 10 per cent of the drug absorption bandwidth at half-height, the observed absorbance will be lower than the 'true' limiting value for monochromatic radiation. Thus, sharp bands are more susceptible than broad bands to absorbance error on this account. Moreover, if the absorbing species is non-homogeneous, or if it undergoes association, dissociation, photodegradation, solvation, complexation or adsorption, or if it emits fluorescence, then positive or negative deviations from the Beer-Lambert Law may be observed. Stray-light effects and the type of solvent used may also lead to non-compliance with the Beer-Lambert Law. It follows that the validity of the Beer-Lambert Law should be established for each drug under the measurement conditions to be used over an appropriate concentration range. For single-beam instruments, the absorbance range for precise measurements is between about 0.3 and 0.6 absorbance unit, the optimum being at 0.43 absorbance unit. For double-beam spectrophotometers, the optimum range lies between 0.6 and 1.2 absorbance unit. Five or more standard solutions, whose absorbances span the working range, should be measured in duplicate in a matched pair of cells against the solvent as reference; the residual

absorbance difference between the cells when filled with solvent (the cell constant) should be subtracted from each individual measurement and should be checked regularly. The graph of absorbance (A) versus concentration (c) should indicate whether any systematic positive or negative deviation is apparent; if so, then additional points should be inserted and the linear working range established. Another test for linearity is to plot the function A/bc (the absorptivity) against concentration of drug, when a horizontal graph indicates compliance with the Beer-Lambert Law.

Stray-light Effects

Stray light is radiation at wavelengths different from those desired. It may arise from light-scattering or other defects within the instrument, or it may be caused by external radiation. If the stray light is not absorbed, the observed absorbance will tend to a constant value as the concentration of drug is increased, thereby yielding a negative deviation from the Beer-Lambert Law.

Stray-light errors are more likely to be observed near the wavelength limits of an instrument, where the radiation intensity of the source and the efficiency of the optical system are reduced, especially below 220 nm and at the crossover point between the ultraviolet and the visible lamps (about 320 to 400 nm). Errors may become serious where the solvent absorbs strongly or where a strongly-absorbing sample is measured by difference spectrophotometry.

The Influence of Solvent

The solvent often exerts a profound influence on the quality and shape of the spectrum. For example, many aromatic chromophores display vibrational fine structure in non-polar solvents, whereas in more polar solvents this fine structure is absent due to solute-solvent interaction effects. A classic case is phenol and related compounds which have different spectra in cyclohexane and in neutral aqueous solution. In aqueous solutions, the pH exerts a profound effect on ionisable chromophores due to the differing extent of conjugation in the ionised and the non-ionised chromophore. In phenolic compounds, for example, addition of alkali to two pH units above the pK_a leads to the classical 'red' or *bathochromic shift* to longer wavelength, a loss of any fine structure, and an increase in molar absorptivity (*hyper chromic*

effect). The bathochromic shift is often large ($>10\text{nm}$) and can be of great diagnostic value. This effect has been exploited, both for qualitative and quantitative purposes, for the analysis of barbiturates. In acidic or neutral solution, barbiturates show little absorption above 230 nm (Fig. 2), but in 0.05M borax buffer (pH 9.2), ionisation yields an intense conjugated chromophore (Fig. 3) with a well-defined maximum near 240 nm ($A=400$ to 450). In sodium hydroxide solution (pH 13), a second stage of ionisation occurs (except in *N*-substituted derivatives) to extend further the conjugation, giving a peak maximum near 255 nm (Figs 2 and 3). However, solutions in alkali are unstable due to ring-opening so that measurements must be made rapidly.

Fig. 2. Effect of pH on the ultraviolet spectrum of phenobarbitone. A, non-ionised barbiturate in 0.1M hydrochloric acid; B, mono-anion in 0.05M borax buffer (pH 9.2); C, di-anion in 0.5M sodium hydroxide (pH 13).

Fig. 3. Dissociation of C_5 -substituted barbituric acids. A, undissociated free acid; B, mono-anion; C, di-anion.

The 'blue' or *hypsochromic shift* to shorter wavelengths is shown by aromatic amines. On acidification, the protonated quaternary ammonium group no longer participates in the chromophore so

the spectrum is shifted to lower wavelengths, sometimes by as much as 30 nm, with a sharp fall in absorptivity (*hypochromic effect*).

In addition to their use for characterising a chromophore, pH-induced shifts can also be exploited to shift a spectrum along the wavelength scale to obtain an interference-free window for measurement of an ionisable species in a mixture. The quality of spectral measurement is directly affected by the type and purity of the solvent used. Each solvent has a cut-off wavelength (corresponding to about 10% transmittance) and this varies with solvent purity (Table 1). A solvent should not be used below its cut-off wavelength even though reference cell compensation is employed, because of the greater risk of stray-light effects. The ultraviolet spectra of some solvents are illustrated on p.203.

Table 1. Cut-off points equivalent to 10% transmittance for spectroscopic solvents

<i>Solvent</i>	<i>Wavelength</i> nm
Water (distilled) or dilute inorganic acid	190
Acetonitrile	210
Butyl alcohol	210
Cyclohexane	210
Ethanol (96% v/v)	210
Heptane	210
Hexane	210
Isopropyl alcohol	210
Methanol	210
Ether	220
Sodium hydroxide (0.2M)	225
Ethylene dichloride	230
Methylene chloride	235
Chloroform (stabilised with ethanol)	245
Carbon tetrachloride	265
<i>NN</i> -Dimethylformamide	270
Benzene	280
Pyridine	305
Acetone	330

Some cautionary comments may be appropriate at this point. It is better to use single- or double-distilled water, and to avoid deionised water, which can be contaminated with absorptive fragments of ion-exchange resin or contain bacterial metab-olites; these can contribute significantly to nonspecific absorption at low wavelengths. Ethanol is normally used as the 96% v/v strength, since dehydrated alcohol is usually contaminated with traces of benzene added to form the azeotropic mixture for distillation. Acetonitrile can vary noticeably in quality, depending on the supplier; the grade supplied for use in HPLC is usually to be

recommended. Acetone, sometimes used to clean cells, is highly absorptive and not always easily removed, despite its volatility and aqueous solubility. Chloroform and carbon tetrachloride absorb strongly at about 250 nm and should therefore only be used for measurements at wavelengths above about 280 nm. Ether, although transparent down to 220 nm, presents particular problems due to its volatility (unstable standard solutions) and inflammability. Although absorptivity is considered to be relatively insensitive to temperature changes, organic solvents in general suffer from high temperature coefficients of expansion, so that for ultimate precision a cell provided with a thermostat may be required.

Instrumentation

Calorimeters. These usually employ a single tungsten radiation source in combination with broad-band (~30 nm) optical filters of nominal wavelength, or narrow bandwidth interference filters with a defined wavelength for use in the visible range. The range of linearity of the colorimeter may be constrained by the relatively broad spectral bandwidths employed, and therefore should be carefully checked for each type of assay.

Single-beam Spectrophotometers. These differ from the colorimeter in using a prism or a high quality diffraction grating monochromator, together with an additional intense source of ultraviolet radiation, usually a deuterium (or hydrogen) lamp. They are capable of high precision, particularly in the optimum absorbance range (0.3 to 0.6 absorbance units). The reference and sample cells must be manually moved in and out of the radiation beam at each wavelength, and it is not practicable, therefore, to scan a spectrum using this device.

Double-beam Spectrophotometers. These use similar high quality optical components to those in the single-beam instrument. However, the radiation from the monochromator is split into two identical beams by a rotating mirror. One beam passes through the sample and the other through the reference cell, before being recombined to focus on the detector. Each signal is processed appropriately by the detector electronics to measure the absorbance 10 to 20 times per second, which gives full compensation for cell and solvent absorption. A scan motor drives the monochromator to give a constant wavelength change per second, and this is synchronised with a recorder or digital plotter to present the spectrum. For broad bands, scan speeds that up to 2 nm/s

that up to 2 nm/s can be employed. However, some computer-controlled spectrophotometers with fast data-processing capabilities can scan at rates approaching 20 nm/s, while maintaining spectral fidelity even for sharp peaks.

Rapid-scanning Spectrophotometers. These employ multi-channel detectors. The most commonly encountered detector of this type is the linear photodiode array. The reversed-optics mode is employed, so that radiation is passed through the sample or reference cell, then dispersed by a diffraction grating polychromator and detected by a device which comprises several hundred diodes. Each photodiode registers the integrated intensity of radiation incident on it which is determined by the spectral dispersion: photodiode ratio. If, for example, a 200-nm bandwidth of radiation were dispersed across 256 photodiodes, the nominal resolution per photodiode would be 0.78 nm.

A spectrum in a specified range is acquired within 20 milliseconds. The analogue signals from each photodiode are digitised and transferred to a computer, where they are corrected for dark current response and transformed to absorbance. A number of digital techniques are available to increase sensitivity and to extend the use of rapid-scanning detectors to multicomponent analysis, reaction kinetics, tablet dissolution tests, process control, and detection in HPLC (A. F. Fell *et al.*, *Chromatographia*, 1982, 16, 69-78).

Absorption Cells

In the visible region, a matched pair of glass cells can be used, but they are inappropriate for the ultraviolet region, due to the poor transmission properties of glass in this range. Fused silica or quartz cells have high transmittance from 190 to 1000 nm, and are therefore the cells of choice. The path-length employed is usually 1.00 cm; longer path-length cells are used for poorly absorptive drugs and/or where the concentration is low. Flow cells designed to minimise turbulent flow through the cell are used for monitoring changes in absorbance during a reaction, for tablet dissolution studies, or for HPLC; care should be taken that the cell walls do not block the radiation beam, otherwise variable errors are introduced. Cells provided with a thermostat are used for studies on enzymatic and other processes where temperature is a key parameter.

The meticulous handling and care of cells is a necessary condition for precise and accurate meas-

urement. Cells should be carefully cleaned, filled with an appropriate solvent, and matched for absorbance to less than 1%. Each pair of cells should be marked on the base in soft pencil to identify the set and its normal orientation. It is convenient to designate the more strongly absorbing cell as the 'sample' cell, the other cell being coded as 'reference'. In this way the cell constant (i.e. the difference in absorbance at the measurement wavelength when filled with solvent) will be positive and can thus be subtracted from each absorbance reading. Moreover, the possibility of 'oscillating error' introduced by randomly changing the cell orientation during a series of measurements is eliminated. The 'cell constant' should be regularly checked at the measurement wavelength when filled with an appropriate solvent, or by scanning the baseline over the wavelength range.

Cells should be scrupulously cleaned after use. If they have contained aqueous solutions, they can be readily cleaned by repeated rinsing with distilled water or by soaking overnight in a very dilute solution of detergent; special detergents should be used for the cleaning of cells contaminated with biological material. Periodically, it is good practice to soak cells and stoppers thoroughly in a fresh solution of chromic acid, followed by copious rinsing with distilled water, in order to restore their matched performance. Cells that have been used with organic solvents require special care, a sequence of solvents ending in spectroscopic ether being convenient for obtaining dry, clean cells. In all cases, the manufacturer's instructions should be followed, when available. Sharp glass or metal objects should not be introduced into a cell, lest the internal surface be scratched. The outside optical surfaces should be polished before use with a soft cloth or photographic lens tissue. Cells should be stored in pairs, dry, and in a protective container.

Standardisation

Standards for calibration of absorbance and wavelength are necessary. Certified nichrome metal film filters can be used in the ultraviolet range but usually a solution of pure potassium dichromate is used, for which accepted specific absorbance values are known (Table 2). Other standards which have been proposed for the ultraviolet range are potassium nitrate in water and potassium chromate in dilute potassium hydroxide solution; for the visible range, copper sulphate and ammonium sulphate have been used.

Table 2. Calibration standards

Standard solution	Wave-length nm	Specific absorbance A_1^1 at 20°
Potassium dichromate 60 mg/litre in 0.005M sulphuric acid	235	124.5 (± 1.6)*
	257	144.0 (± 1.6)*
	313	48.6 (± 1.6)*
	350	106.6 (± 1.6)*
Potassium chromate 25 mg/litre in 0.04M potassium hydroxide	373	248.5 (± 1.0)†
Potassium nitrate 10 g/litre in water	262.5	0.148
	302	0.705 (± 0.005)†

*British Pharmacopoeia, London, HMSO, 1980, Appendix IIB.

†J. R. Edisbury, *Practical Hints on Absorption Spectrometry*, London, Hilger, 1966.

For the wavelength scale, the British Pharmacopoeia (1980) permits a tolerance of ± 1 nm in the range 200 to 400 nm and 4.3 nm in the range 400 to 600 nm, based on calibration with either holmium perchlorate solution or the emission lines of mercury, deuterium, or hydrogen discharge lamps. However, the most widely used standard is the holmium oxide glass filter (principal peaks at 241.5, 279.4, 287.5, 333.7, 360.9, 418.4, 453.2, 536.2, and 637.5 nm). Neodymium glass filters are also used for additional data in the visible region.

In some assays it is necessary to specify the minimum desirable resolution, since changes in the spectral bandwidth (or monochromator slit-width) can seriously affect the observed absorbance of sharp peaks. The British Pharmacopoeia (1980) requires that the spectral bandwidth employed should be such that further reduction does not lead to an increase in measured absorbance. This is particularly important for drugs that have aromatic or strongly-conjugated systems, e.g. diphenhydramine, phenoxymethylpenicillin, and amphotericin A and B. In such cases, a spectral bandwidth of more than 1 nm leads to a reduction in observed absorbance at the peak maximum (and conversely an increase in absorbance at a peak minimum), since the recorded absorbance is the mean of that over the whole bandwidth at that wavelength. Although increasing the slit-width gives a better signal-to-noise ratio, a slit-width of 2 nm is adequate for most bands, with 1 nm or 0.5 nm being used for very sharp peaks.

The level of stray light should be assessed since it increases with instrument age. The British Pharmacopoeia (1980) requires that the absorbance at 200 nm of a 1.2% w/v solution of potassium chloride should exceed 2 absorbance units with respect to water as reference. Alternatively a glass Vycor filter can be used, since its absorption increases sharply at the cut-off wavelength of 210 nm; any reading below this is attributable to stray light. The United States Pharmacopoeial Convention

distributes certified reference standards for comparative analysis of a sample. The use of reference materials eliminates local differences in spectrophotometric performance but requires a considerable effort to ensure the continued validity of the standards.

QUANTITATIVE APPLICATIONS

Pharmacopoeial applications include assays for single drugs and mixtures of drugs, analyses involving colour reactions (colorimetric methods), tests for tablet dissolution, limit tests for impurities, and assays of bulk drugs or an extract thereof. Further applications are for physicochemical measurements, such as pK_a or velocity constants in enzymatic reactions. The scope of such applications has been significantly extended by methods which can confer additional specificity, namely difference spectrophotometry and derivative spectrophotometry.

SINGLE COMPONENTS

Where only one component in the sample absorbs significantly, the wavelength is chosen to coincide with the centre of a broad maximum in the spectrum to minimise wavelength-setting errors. If the spectrum has no suitable maximum, a flat absorption minimum can be used, provided that the consequent loss of sensitivity is acceptable. Wavelengths near the extremities of the ultraviolet and visible ranges must be avoided, because of the danger of stray-light errors.

Assuming that the linear range for compliance with the Beer-Lambert Law has been established and that the drug concentration has been adjusted within the optimum range for the type of instrument concerned, then two approaches to quantification may be employed. If an acceptable reference standard of the drug is available, and if the calibration graph passes through zero, measurement of replicates of the standard (at a comparable concentration) and of the tests are performed in bracketing sequence (i.e. each group of samples is preceded and followed by the standard), under identical conditions of solvent and temperature and using the same pair of matched cells. Each result should be corrected for the cell constant; the concentration of the test sample is then found by reference to the results from the standards.

Alternatively, the specific absorbance is used to calculate the sample concentration, using the absorbance measured in the specified solvent. A

check on the accuracy of the absorbance scale is clearly essential. Wavelength accuracy is not so important.

Accurate measurements of a drug in solution may be difficult due to non-specific absorption. In these circumstances, the geometric correction devised by Morton and Stubbs is sometimes applied. This assumes that the non-specific absorption varies linearly with wavelength over the range measured. Taking a solution of pure drug, two equi-absorptive points are selected, one at a lower wavelength (λ_1) and the other at a higher wavelength (λ_3) than that of the peak maximum (λ_2). Any irrelevant absorption in the sample increases the observed absorbance of one equi-absorptive point (usually λ_1) more than the other (λ_3). A simple geometrical calculation involving absorbances at λ_1 and λ_3 enables the absorbance at λ_2 to be corrected for the non-specific absorption (M. Donbrow, *Instrumental Methods in Analytical Chemistry*, Vol. II—Optical Methods, London, Pitman, 1967). The assumption of linearity of the irrelevant absorption can be tested by subtracting the theoretical curve for the calculated quantity of pure material and inspecting the residual difference spectrum.

The classic example of a pharmacopoeial assay based on the Morton-Stubbs correction is that for vitamin A alcohol and the ester. Other techniques proposed for the correction of non-specific absorption include difference spectrophotometry, second derivative spectrophotometry, the use of orthogonal polynomials, and chemical or physical transformation of the drug to give absorption at a longer wavelength.

MULTICOMPONENT SYSTEMS

The absorption spectra of two or more drugs of interest often overlap. Subject to certain conditions, the Vierordt method of simultaneous equations can be employed to obtain the individual concentrations (A. L. Glenn, *J. Pharm. Pharmac.*, 1960, 72, 598-608). If each of n drugs obeys the Beer-Lambert Law over the concentration range of interest, and if the law of additivity of absorbances applies, then the total absorbance, A_T^λ observed at any wavelength λ is given by the sum

$$A_T^\lambda = \sum_{i=1}^n A_i^\lambda = \sum_{i=1}^n k_i^\lambda \cdot c_i \cdot b$$

where the subscript i denotes each component in the system. The term k_i^λ represents the absorptivity a (litre/g/cm), the specific absorbance ($A_{\text{cm}}^\%$), or

the molar absorptivity ϵ (litre/mol/cm), as determined by the units selected for concentration c_i .

For a two-component system, two wavelengths λ_1 and λ_2 are selected (as discussed below) and two corresponding simultaneous equations set up

$$A_T^{\lambda_1}/b = k_1^{\lambda_1} \cdot c_1 + k_2^{\lambda_1} \cdot c_2$$

$$A_T^{\lambda_2}/b = k_1^{\lambda_2} \cdot c_1 + k_2^{\lambda_2} \cdot c_2$$

These readily yield the concentration of each component, c_1 and c_2 , by conventional algebra.

The selection of appropriate wavelengths and the use of accurate absorptivity values are clearly crucial. Generally λ_1 is the λ_{max} for component 1, while λ_2 is the λ_{max} for component 2, provided that at these wavelengths the absorptivity of the overlapping component is small. If the spectra of both components are very similar, the errors of the method increase appreciably as the difference between the absorptivity ratios tends to zero.

Although this method should apply to the analysis of three or more components, in practice it is often difficult to select wavelengths which fulfil all the requisite conditions. However, computer-aided spectrophotometers exploit the 'principle of over-determination', where the number (n) of observation wavelengths exceeds the number (n) of components known to be present. This gives an $n \times m$ matrix of data which can be readily solved by standard matrix algebra.

The limit test for amphotericin A (a tetraene, λ_{max} 300 nm) in the antifungal antibiotic amphotericin (consisting primarily of amphotericin B, a hepta-ene, λ_{max} 380 nm) is an example of such a two-component analysis (British Pharmacopoeia, 1980).

Colorimetric Measurements

Colorimetric methods can selectively transform a drug, its impurity, or a metabolite so that the spectrum is shifted to the visible region and away from interference caused by another drug, formulation components, or biological substances, thereby conferring a further degree of specificity. Moreover, a drug with little or no useful absorption can be more sensitively determined by modifying it to a more highly-absorptive chromophore.

There are several parameters which require critical consideration. Firstly, the colour reagent should be selective for the drug molecule itself, discriminating against degradation products, impurities, and formulation excipients likely to be present. Secondly, the effect and control of any parameters likely to affect the colour reaction should be established, i.e.

solvent, pH, temperature, reagent excess, order of mixing reagents, ageing of reagents, and related factors. Moreover, the time required to establish a stable absorbance plateau and the stability of the chromophore generated, should be carefully assessed. Finally, the analytical performance should be established in terms of recovery, precision, sensitivity, linear range, and robust behaviour.

An interesting example is the assay of clonidine hydrochloride in injections and tablets (British Pharmacopoeia, 1980). In 0.01 M hydrochloric acid, clonidine exhibits two sharp maxima near 272 nm and 279 nm, which are not suitable for precise measurement. However, clonidine forms an ion pair with bromothymol blue, and this can be readily extracted into chloroform for subsequent measurement of the broad maximum near 420 nm. Because of the intrinsic variability of reagents used in such methods, a pharmacopoeial reference standard is employed for calibration. A similar policy is adopted for assays involving chemical modification of the drug, as in the tetrazolium assay for corticosteroids, the assay for folic acid involving hydrolysis, diazotisation, and coupling with *N*-(1-naphthyl)ethylenediamine, and the reaction of penicillins with imidazole and mercuric salts.

Difference Spectrophotometry

Difference Spectrophotometry is a method of compensating for the presence of extraneous materials in a sample which would otherwise interfere with the spectrum of the drug being determined. It involves the measurement of the absorbance difference, at a defined wavelength, between two samples in one of which a physical or chemical property of the drug has been changed. It is assumed that the spectrum of the drug can be changed without affecting the spectrum of the interfering material. Alternatively, the absorbance difference may be measured between the sample and an equivalent solution without the drug. Difference Spectrophotometry is sometimes described as 'differential Spectrophotometry', but this term is not recommended because of its possible confusion with derivative Spectrophotometry.

Many suitable methods for physical and chemical modification of the drug absorbance have been reported. For example, the bathochromic effect is used in the difference spectrophotometric assay of barbiturates. The absorbance of the sample at about pH 10 (A_{10}), where the mono-anionic species contributes (A_B), is used to compensate for the

absorption of interfering endogenous materials (A_M) which have been carried through the extraction procedure. The sample absorbance at pH 13 (A_{13}), where the di-anionic species (A_D) contributes, is measured at about 260 nm with reference to the sample absorbance at pH 10 (A_{10}), so that

$$\begin{aligned} A_{13} &= A_D + A_M \\ A_{10} &= A_B + A_M \end{aligned}$$

thus

$$\Delta A = A_{13} - A_{10} = A_D - A_B$$

if

$$\begin{aligned} \Delta \epsilon &= (\epsilon_D - \epsilon_B) \\ \Delta A &= \Delta \epsilon bc \end{aligned}$$

Thus the difference absorbance can be readily related to concentration by prior calibration of the constant, $\Delta \epsilon$, or the concentration may be found by simple proportion

$$\Delta A_{\text{test}} / \Delta A_{\text{standard}} = c_{\text{test}} / c_{\text{standard}}$$

It should, however, be established that ΔA is a linear function of concentration (c) over the range required. It is convenient to select for the analytical wavelength a value corresponding to a maximum in the difference spectrum, obtained by scanning the sample and reference solution over an appropriate wavelength range.

Difference Spectrophotometry can be used for quality control in cases where the interfering material is well-defined, because an appropriate dilution of a suitable reference solution can be used in the reference cell. The difference absorbance is, however, susceptible to systematic error when there is uncertainty in the concentration of interfering materials in the samples to be assayed. This error increases in proportion to the ratio of the molar absorptivity of the interference to that of the drug. A further technique to correct for absorptive interferences by difference measurement is based on *dual-wavelength spectrophotometry*. In this method, two monochromatic beams at different wavelengths are passed through the same sample. One wavelength (λ_1) is generally characteristic of the drug, while the other (λ_2) is carefully selected so that the absorbance is equivalent to the level of absorptive interference ($A_m^{\lambda_1}$) anticipated at the analytical wavelength (λ_1). Thus, the second radiation beam is analogous to the reference cell employed in conventional difference Spectrophotometry, and the difference in absorbance at the two wavelengths (ΔA) represents the

absorption of drug (A_n^{λ}) corrected for interference

$$A^{\lambda_1} = A_n^{\lambda_1} + A_m^{\lambda_1}$$

and since

$$A^{\lambda_2} = A_m^{\lambda_2}$$

then

$$\Delta A = A^{\lambda_1} - A^{\lambda_2} = A_n^{\lambda_1}$$

A classic application of this method is the correction of Rayleigh scatter in samples of biological origin.

Derivative Spectrophotometry

In derivative Spectrophotometry the absorbance (A) of a sample is differentiated with respect to wavelength (λ) to generate the first, second, or higher order derivatives

$$\begin{array}{ll} A = f(\lambda) & dA/d\lambda = f'(\lambda) \\ \text{zero order} & \text{first derivative} \\ d^2A/d\lambda^2 = f''(\lambda), \text{ etc.} & \\ & \text{second derivative} \end{array}$$

Derivative spectra often yield a characteristic profile, where subtle changes of gradient and curvature in the normal (zero order) spectrum are observed as distinctive bipolar features (Fig. 4).

The first derivative of an absorption spectrum, represents the gradient at all points of the spectrum and can be used to locate 'hidden' peaks, since $dA/d\lambda = 0$ at peak maxima (Fig. 4). However, second and higher even-order derivatives are potentially more useful in analysis.

The even-order derivatives are bipolar functions of alternating sign at the centroid (i.e. negative for 2nd, positive for 4th, etc.), whose position coincides with that of the original peak maximum (Fig. 4). To this extent, even-derivative spectra bear a similarity to the original spectrum, although the presence of satellite peaks flanking the centroid adds a degree of complexity to the derivative profile. A key feature is that the derivative centroid peak width of a Gaussian peak decreases to 53%, 41%, and 34% of the original peak width, in the second, fourth, and sixth orders respectively. This feature can increase the resolution of overlapping peaks. However, the increasingly complex satellite patterns detract from resolution enhancement in higher derivative spectra.

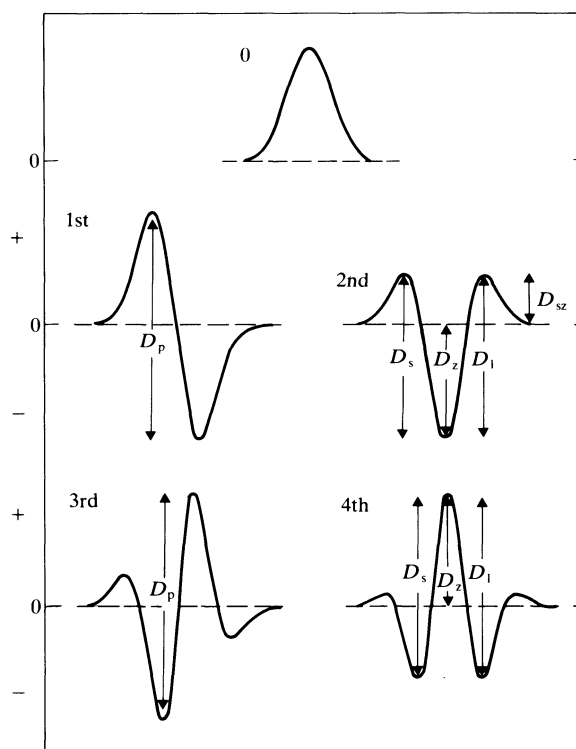

Fig. 4. First to fourth derivatives of a Gaussian peak, and some graphical measures of derivative amplitude (D). D_p , peak-to-peak; D_s , peak-to-satellite at short wavelength; D_z , peak-to-derivative zero; D_l , peak-to-satellite at long wavelength; D_{sz} , satellite peak-to-derivative zero.

An important property of the derivative process is that broad bands are suppressed relative to sharp bands. This effect increases with increasing order of the derivative since the amplitude (D_n) of a Gaussian peak in the n th derivative is inversely related to the original peak width (W), raised to the n th degree

$$D_n \propto (W)^{-n}$$

Thus, for two coincident peaks of equal intensity, the n th derivative amplitude of the sharper peak (X) is greater than that of the broader peak (Y) by a factor which increases with derivative order

$$\frac{D_{n,X}}{D_{n,Y}} = \left[\frac{W_Y}{W_X} \right]^n$$

This property leads to the selective rejection of broad, additive, spectral interferences such as Rayleigh scattering.

If the Beer–Lambert Law is obeyed, i.e.

$$A = \epsilon bc$$

then

$$\frac{dA}{d\lambda} = \frac{d\epsilon}{d\lambda} \cdot b \cdot c$$

$$\frac{d^2A}{d\lambda^2} = \frac{d^2\epsilon}{d\lambda^2} \cdot b \cdot c$$

and similarly for higher derivatives, where ϵ = molar absorptivity (litre/mol/cm), b = cell path-length (cm), and c = concentration (mol/litre).

For quantitative work, the amplitude of a derivative peak can be measured in various ways (Fig. 4). Although the true derivative amplitude is that measured with respect to the derivative zero, the most common practice is to record the amplitude with respect to a satellite in the spectrum which affords an extra degree of suppression of interference from extraneous substances. It is essential to run standards in bracketing sequence with samples, thus subjecting both to the same experimental conditions. It should be established that the graphical derivative adopted fulfils the analytical criteria of linear response with concentration, regression through or close to the origin, independence from interfering substances, and optimum precision.

In general, methods for generating derivative spectra fall into two classes. These are optical methods, which operate on the radiation beam itself, and electronic or digital methods operating on the photometric detector output. The electronic analogue device generates the required derivative as a function of time as the spectrum is scanned at constant speed ($d\lambda/dt$) and therefore the derivative amplitude varies with the scan speed, slit-width, and gain. Moreover, the signal-to-noise ratio has been reported to degrade by approximately a factor of two in each successive derivative order.

Alternatively, a microcomputer can be used, employing one of a number of digital algorithms to produce smoothed derivative spectra. This is done in real time or by post-run processing of the digitised spectrum. The digital approach is increasingly employed in contemporary spectrophotometers, due to the widespread adoption of microprocessors for instrument control and data handling, coupled with the addition of dedicated microcomputers for further data processing capability.

Although transformation of a spectrum to its second

or higher order derivative often yields a more highly characteristic profile than the zero order spectrum, the intrinsic information content of the data is not increased; indeed, some data, such as constant 'offset' factors, are lost. However, the derivative method tends to emphasise subtle spectral features by presenting them in a new and visually more accessible way. The method is generally applicable in analytical chemistry and can be used equally for resolution enhancement of electrochemical, chromatographic, or thermal analysis data.

Derivative spectrophotometry has found significant application in clinical, forensic, and biomedical analysis. In forensic toxicology the suppression of the absorbance due to interfering substances by second derivative spectrophotometry is well demonstrated in studies on amphetamine in an homogenised liver extract (Fig. 5). Transformation of the zero order spectrum (A) to its second derivative (B) using a rapid-scanning multi-channel spectrophotometer permits the characteristically sharp benzenoid peaks of amphetamine to be detected and compared with an authentic standard (D), while the interfering background absorption is substantially reduced. The second and fourth derivative method for biological background correction can give a ten-fold increase in the detection limit of serum paraquat in cases of poisoning (A. F. Fell *et al.*, *Clin. Chem.*, 1981, 27, 286-292). The derivative method can be successfully combined with difference spectrophotometry, to give second derivative-difference spectra, when enhanced discrimination against interfering substances and sharpened fine structural features are observed.

QUALITATIVE APPLICATIONS

Specific identification of a compound can rarely be made on the basis of spectral evidence alone. Often the spectrum serves as confirmatory evidence of identity, in support of other analytical data. The general approach usually followed in qualitative applications is first to establish by independent means (e.g. chromatography) that the material consists of substantially one absorbing component. Spectra are then recorded in aqueous acidic, basic, and in ethanolic or methanolic solution. The wavelengths of the principal peaks and the corresponding absorptivity values are noted for each solvent system. By comparison with data tabulated in ascending wavelength order (see the index of Ultraviolet Absorption Maxima in Part 3), a number of compounds with absorbing properties similar

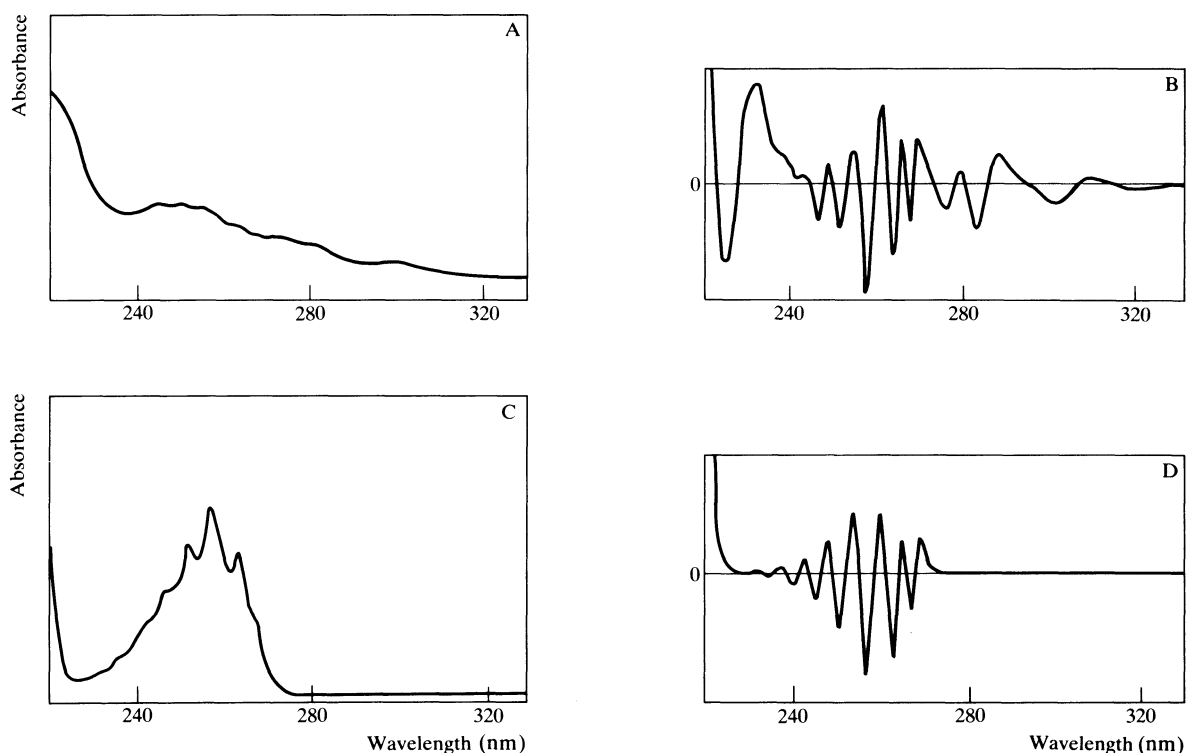

Fig. 5. Detection of amphetamine in homogenised liver extract. Standard zero order (A), and second derivative (B) spectra of the liver extract, compared with the standard zero order (C) and second derivative (D) spectra of amphetamine; solutions were in 0.1M sulphuric acid. (From R. Gill *et al.*, *J. forens. Sci. Soc.*, 1982, 22, 165–171.)

to the test substance are selected (using a wavelength window of 4:2 nm).

Further evidence can be deduced from the absorptivity ratios of peaks within a spectrum; moreover, the change in these ratios together with the shift in peak positions as the pH is changed can be diagnostic. If a drug molecule ionises reversibly (i.e. without degradation), the family of curves for a constant concentration in acidic and basic solvents will display one or more isosbestic points at characteristic wavelengths, where the absorbance is constant at all values of pH.

Spectral shifts are among the most useful diagnostic features in drug molecules possessing ionisable groups. A marked bathochromic shift in alkaline solution is observed not only for most of the phenolic drugs such as the phenolic oestrogens, but also in the case of hydroxypyridines, ketones, benzodiazepines, pyridones, and nitro-compounds. The barbiturates display a marked bathochromic shift in alkaline solution to give characteristic maxima at about 240 nm (pH 9.2) and 255 nm (pH 13), as discussed above. The hypsochromic shift is shown

by aromatic amines in acid solution and is highly characteristic for many drugs. Further diagnostic detail can also be obtained by reducing the solvent polarity for compounds which form hydrogen bonds in aqueous solvents.

Fluorescence Spectrophotometry

Fluorescence radiation, emitted by a sample which is illuminated at a defined excitation wavelength, is one of several types of luminescence phenomena. Fluorescence Spectrophotometry is by far the most widely used luminescence technique in practice, primarily because of its intrinsic sensitivity and selectivity. The sensitivity is generally greater than that achieved by absorption Spectrophotometry in which, at low drug concentrations, accurate and precise measurement of the difference in intensity of the two similar beams of radiation, I_0 and I , becomes progressively more difficult. By contrast, the intensity of fluorescence is essentially measured against a 'dark' background, or at least a background with relatively low fluorescence emission.

Although in biological samples the fluorescence intensity of interfering substances may be relatively high, the sensitivity and selectivity of the method is generally such that fluorescent drugs and their metabolites can be analysed more readily than by conventional spectrophotometry.

The selectivity arises from the requirement that two wavelengths are involved—the excitation wavelength (λ_{ex}) and the fluorescence emission wavelength (λ_{f}). Moreover, the ability of a molecule to fluoresce is in itself a characteristic which discriminates it from the many compounds which do not display significant fluorescence. The fluorescence phenomenon involves the absorption of excitation radiation by a molecule which then loses energy by internal conversion processes, before emitting a photon of radiation at lower energy. The excitation wavelength maximum (λ_{ex}) is lower than the wavelength of maximum fluorescence emission (λ_{f}), from which it is separated by a characteristic interval described as the *Stokes shift*.

The variety of sampling methods available in spectrofluorimetry makes it a very versatile technique. The most frequent mode of sample presentation is as a dilute solution, although gases, suspensions, and solid surfaces can also be examined. Combinations of spectrofluorimetry with thin-layer chromatography and high pressure liquid chromatography are particularly advantageous for sensitive and selective detection of fluorophores.

Instrumentation

In most conventional single-beam spectrofluorimeters, fluorescence is observed at right angles to the axis of the excitation radiation, to provide a convenient means for optical discrimination between λ_{ex} and λ_{f} (Fig. 6). Simple filter instruments employ an intense source of radiation (usually a mercury or a xenon lamp) with primary (excitation) and secondary (emission) filters in the right-angle configuration, a cylindrical or oblong clear quartz cell, and a photomultiplier detector. More complex spectrofluorimeters employ two diffraction gratings (or prisms) to select λ_{ex} and λ_{f} , together with a high-intensity xenon source, scanning motors, and electronic compensation for variations in source intensity as the wavelength is varied.

An excitation spectrum is obtained by monitoring the fluorescence at a convenient fixed wavelength (λ_{f}) while scanning the excitation monochromator at a fixed speed up to a wavelength no higher than

spectrum; however, differences arise due principally to the distortion imposed by the instrumental response characteristic of the spectrofluorimeter. λ_{f} (Fig. 7). The excitation spectrum should, in principle, be comparable with the absorption spectrum; however, differences arise due principally to the distortion imposed by the instrumental response characteristic of the spectrofluorimeter.

Fig. 7. Excitation, fluorescence, and synchronously-scanned spectra of oestrone in ethanol, and their second derivatives. A, excitation spectrum monitored at a fluorescence wavelength, λ_{f} ; B, fluorescence spectrum obtained at an excitation wavelength, λ_{ex} ; C, synchronously-scanned spectrum obtained with a constant interval, $\Delta\lambda_{\text{s}}$, between the excitation and emission monochromators. (From A. F. Fell, in *Proc. 1st Symp. Anal. Steroids, Eger, Hungary*, S. Görög (Ed.), Amsterdam, Elsevier Press, 1982, pp. 495–510.)

The fluorescence spectrum is obtained by illuminating the sample at a convenient fixed excitation wavelength (λ_{ex}) and scanning the emission mono-chromator at a fixed speed over a wavelength range no lower than λ_{ex} (Fig. 7). For interlaboratory comparisons, corrected fluorescence and excitation spectra should be obtained using one of the generally available digital or instrumental techniques.

Some spectrofluorimeters are capable of scanning the excitation and the emission monochromators synchronously (synchronous-scanning or synchronous-excitation fluorimetry) to yield fluorescence spectra which are generally simpler and considerably sharper than the conventional fluorescence spectrum as indicated in Fig. 7. With computer-aided spectrofluorimetry, the acquisition and digital storage of fluorescence spectra are possible. These can then be manipulated in various ways to give the derivative spectrum where fine structure is accentuated (Fig. 7), the difference spectrum, or multi-wavelength spectral deconvolution for calculating the concentration of known overlapping components (S. A. Winfield *et al.*, *J. pharm. biomed. Analysis*, 1984, 2, 561-566). In another digital technique, a series of fluorescence spectra are acquired while sequentially stepping the excitation wavelength. When these spectra are combined to give a matrix of (I_f , λ_f , λ_{ex}), a three-dimensional isometric projection is presented. This type of graphical presentation is described as an 'emission-excitation matrix' or 'fluorogram' (Fig. 8). The data can also be plotted as the equivalent two-dimensional plot of isointensity contours in the (λ_f , λ_{ex}) plane (Fig. 9). The three-dimensional graphics are finding increasing use for the qualitative comparison of fluorescent molecules, as in the example of promethazine and its principal degradation product (Figs 8 and 9).

Fig. 8. Isometric projection of emission-excitation matrix ('fluorogram') of fluorescence intensity (I_f) for promethazine hydrochloride (A) and promethazine sulfoxide (B) in buffer at pH 3.0. (From A. F. Fell *et al.*, *J. pharm. biomed. Analysis*, 1983, 1, 557-572.)

Fig. 9. Contour plot of emission-excitation matrix of promethazine hydrochloride (A) and promethazine sulfoxide (B) in buffer at pH 3.0. (From B. J. Clark *et al.*, *Analytica chim. Acta*, 1985, 170, 35-44.)

Instrument Standardisation

The calibration of excitation and emission monochromator wavelengths should be checked regularly by the use of sharp lines from the instrument's own radiation source (e.g. xenon lines at 450.1, 462.4, 467.1, and 473.4 nm), or the use of sharp fluorescence peaks in solutions or glasses of trivalent lanthanide ions (Te^{III} , Eu^{III}). Other fluorescence standards in common use are ovulene, and other polycyclic aromatic hydrocarbons with fine vibrational structure, such as naphthalene and anthracene. In practice it is necessary only to calibrate one monochromator, since the other can then be calibrated by the Rayleigh scattered radiation using a sample of colloidal silica in the sample position. The use of an auxiliary light source, such as a mercury light pen, is the least satisfactory method for wavelength calibration.

SIGNAL INTENSITY

Fluorescence is generally more sensitive to environmental factors than absorbance measurements. Signal intensity may be affected by pH, temperature, quenching, interfering substances, solvent, or interference from Rayleigh and Raman scattering. Many fluorescent species contain ionisable groups whose fluorescent properties are sensitive to pH. In some cases only one of the ionised species may be fluorescent. An example is the barbiturates which only fluoresce at elevated pH in the di-anionic form. The relationship of fluorescence intensity with pH should always be examined as part of the development of the method.

An increase in temperature leads to a decrease in the observed fluorescence in dilute solutions due to increased collisional quenching. Since a rise of one

degree can give a decrease of 1 to 2% in fluorescence intensity, it is essential to use a sample cell provided with a thermostat when high precision measurements are required.

Quenching occurs if species are present that can reduce the observed fluorescence by forming complexes with either the ground state or the excited state of the fluorescent molecule. It can be described by the Stern-Volmer Law

$$I_f/I_{f(q)} = 1 + k[Q]$$

where I_f represents the fluorescence intensity in the absence of quenching agent and $I_{f(q)}$ denotes the fluorescence intensity observed in the presence of quencher concentration $[Q]$. This relationship can be used for quantitative analysis, e.g. the analysis of sulphonamides by quenching with 9-chloroacridine. Generally, the fluorescence due to interfering substances in samples of biological origin limits the ultimate sensitivity of a method. Interference can be reduced by suitable sample pre-treatment, the use of spectroscopically pure solvents, triple-distilled water, and scrupulously clean glass-ware. However, when working near the sensitivity limits of an instrument, the variability of the interfering fluorescence detracts significantly from the precision and accuracy of a method. Interference from Rayleigh and Raman scatter is a particular problem when analysing dilute solutions.

Rayleigh scatter results in emission of radiation at the same wavelength as the light source. The intensity of Rayleigh scatter varies inversely with λ^4 , so that its effect is more troublesome at lower wavelengths and when the excitation and emission wavelengths are close.

Raman scatter involves a shift in wavelength which depends on the solvent used, and may thus be confused with fluorescence. Its presence may be detected by changing the excitation wavelength; the wavelength of a Raman peak will change in the same direction, whereas a fluorescence peak will remain at the same wavelength. Interference by a Raman peak can therefore be displaced from an emission band by using an excitation wavelength lower than the excitation maximum, with a consequent loss in sensitivity.

QUANTITATIVE APPLICATIONS

In dilute solution, the fluorescence intensity (I_f) for defined values of λ_{ex} and λ_f is linearly related to

molar concentration (c), according to the approximate relationship

$$I_f = k\phi I_0 \epsilon bc \quad \text{at } \lambda_{ex}, \lambda_f$$

where k = instrumental constant, ϕ = quantum efficiency of fluorescence, I_0 = radiation intensity of source, ϵ = molar absorptivity, and b = cell path-length. These constants can be collectively represented as K , under constant instrumental conditions where

$$I_f = Kc \quad \text{at } \lambda_{ex}, \lambda_f$$

A necessary condition is that the total absorbance ($=\epsilon bc$) of the system should not exceed 0.05 absorbance units, otherwise progressively greater negative deviations from linearity are observed. At high drug concentrations, fluorescence intensity reaches a plateau. Beyond this, fluorescence intensity actually decreases with increasing concentration, due to inner-filter effects, where ground-state molecules absorb the fluorescence emitted by excited molecules.

It is essential to establish the range of linearity of the calibration curve of I_f versus c , using at least five standard solutions, for which the condition that absorbance at the wavelength of maximum excitation is < 0.05 absorbance units holds. Samples are usually analysed by single-point bracketing, taking a standard conveniently close to the anticipated sample value and calculating the result by simple proportion. The sequence of standard measurements before and after measuring the sample permits any baseline drift to be compensated. For additional assay security, two-point bracketing can be employed, where two standard solutions, one higher and the other lower than the concentration observed for the sample are used in bracketing sequence.

Spectrofluorimetry differs from absorption spectrophotometry in not yielding an absolute scale of values. For this reason it is essential to employ a reference standard for quantitative measurements. For example, some pharmacopoeial tests, such as the test for uniformity of content for digitoxin tablets, employ a spectrofluorimetric assay and comparison with an official reference standard. Quantitative Spectrofluorimetry has been proposed for a number of naturally fluorescent compounds, including ergometrine, riboflavine, the catechol-amines, phenothiazines, the barbiturates (at pH 13), and certain antibiotics such as chlortetracycline and oxytetracycline.

The sensitivity and selectivity of spectrofluorimetry have been well-exemplified in forensic and toxicological studies on lysergide. In the case of weakly fluorescent or non-fluorescent drugs, a number of well-characterised derivatisation reactions are available. These include dansyl chloride (5-dimethylaminonaphthalene-1-sulphonyl chloride) for primary and secondary amines and phenolic hydroxyl groups, fluorescamine (4-phenylspiro-[furan - 2(3H), 1' - isobenzofuran] - 3, 3'-dione), and *o*-phthalaldehyde for primary amines.

Derivatisation reactions of this type have significantly extended the scope of fluorescence detection in HPLC. Such developments, coupled with the wider use of laser sources for increased sensitivity and the advent of rapid-scanning fluorimetric detectors, further emphasise the considerable contribution which hybrid detection systems can make in liquid chromatography.

Infra-red Spectrophotometry

D. I. Chapman

Infra-red Spectrophotometry is the study of the reflected, absorbed, or transmitted radiant energy in that region of the electromagnetic spectrum from wavelength (λ) 0.8 to 500 μm . A more commonly used measurement than wavelength is the frequency (the number of waves per unit length). This is expressed in wavenumbers ($\tilde{\nu}$), the units of which are cm^{-1} . The relationship between wavenumber in cm^{-1} and wavelength in μm is given by

$$\tilde{\nu} = \frac{10^4}{\lambda}$$

The infra-red spectrum is usually divided into three regions, 12 500 to 4000 cm^{-1} (0.8 to 2.5 μm) ('near infra-red'), 4000 to 400 cm^{-1} (2.5 to 25 μm) ('mid infra-red'), and 400 to 20 cm^{-1} (25 to 500 μm) ('far infra-red'). Only the mid infra-red region (usually referred to simply as 'infra-red') is considered here because it is the region which is widely used in the analysis of drugs and pesticides. However, some dispersive instruments scan from 5000 to about 200 cm^{-1} and this extension to the far infra-red is useful for halogenated compounds and for inorganic substances.

When a molecule is subjected to infra-red radiation, transitions take place between rotational and vibrational energy levels in the ground electronic state. These transitions give rise to an absorption spectrum characteristic of the compound. This is in contrast to ultraviolet radiation which also causes transitions between rotational and vibrational energy levels, but because of its greater energy these transitions occur at higher energy states. In the infra-red, absorption occurs only where a change of the dipole moment of a molecule can take place. This means that diatomic molecules without di-poles, such as hydrogen, nitrogen, and oxygen, do not absorb in the infra-red. Total symmetry about an absorption band will eliminate certain absorptions, e.g. the symmetrical ethane molecule gives no carbon-carbon stretching absorption bands.

Three main types of absorption occur, namely fundamental, overtone, and combination. Fundamental bands are the primary absorption bands for each mode of vibration, overtone bands occur at

multiples of the fundamental band wavelength, and combination bands occur at wavelengths which are the sum or difference of two or more fundamental bands. Overtone and combination bands are usually much weaker than fundamental bands.

Particular bonds or functional groups in a molecule have specific absorption bands at given wavenumbers. Changes in the wavenumber of a band have been correlated with changes in either the structural environment or the physical state of the molecule. These correlations form the basis of qualitative analytical work in infra-red Spectrophotometry (L. J. Bellamy, 1965). However, many bands in the complex region from 1600 to 400 cm^{-1} , which is usually referred to as the 'fingerprint region', are still of unconfirmed origin. A proportion of the bands are characteristic of the molecule as a whole and cannot be assigned to particular functional groups.

INSTRUMENTATION

Dispersive Spectrophotometers

The basic components of a dispersive infra-red spectrophotometer are shown in Fig. 1. The source of infra-red radiation is an electrically conducting element, such as a Globar or Opperman source, which is maintained at about 1000°.

Infra-red Spectrophotometers can be single- or double-beam instruments, or both facilities may be available. In the double-beam mode, the beam of radiation passes through both the sample and a reference path (or reference cell). The use of a reference cell enables compensation to be made for unwanted absorption, e.g. from solvents. Alternatively, an instrument fitted with computing facilities can record and remember the solvent spectrum and then subtract it from a subsequent spectrum obtained with the same cell.

In optical null instruments, radiation is passed through the sample and reference paths simultaneously or the instrument may be designed to pass the radiation through each path alternately (pre-sample chopping). A wedge or comb attenuator is moved in or out of the reference beam until absorption in both beams is equal. The movement of the

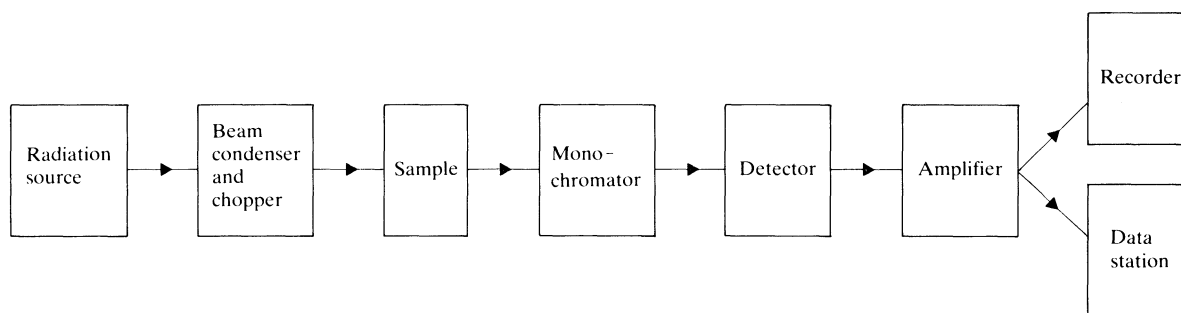

Fig. 1. Schematic diagram of a dispersive infra-red spectrophotometer.

attenuator is linked to the recorder pen which records the spectrum directly. These instruments lack sensitivity when the sample absorption is high, because of the lack of energy to activate the system. Thus, measurements made at below about 15% transmittance are imprecise. This problem is overcome with ratio-recording instruments in which the ratio of the intensities of the sample and reference beams is measured; the pen response remains constant, so enabling precise and reproducible values of the ordinate to be obtained, even at very small transmission values.

The detector may be a thermocouple, a Golay cell (which senses the change of pressure in a gas, caused by the heating effect), or a pyroelectric compound such as triglycine sulphate, and the response is amplified and fed to a recorder and/or data processor. Infra-red spectrophotometers may not always record the correct frequency of the absorption bands because of various errors. Such errors may be inherent in the instrument, errors of adjustment, errors in fitting the paper to the recorder, or in the printing of the paper. The error in the frequency is greater at higher wavenumbers than at lower ones. For older dispersive instruments, the error at 5000 cm^{-1} inherent in the instrument alone can be as large as $\pm 50\text{ cm}^{-1}$, and it is essential to calibrate each spectrum before it is removed from the recorder. With modern dispersive instruments, the error should be $\pm 5\text{ cm}^{-1}$ or less at 5000 cm^{-1} , and within $4:1\text{ cm}^{-1}$ below 2000 cm^{-1} . However, the occasional calibration ensures that the instrument is up to specification.

To calibrate the wavenumber scale, first record the spectrum of the sample and then place a polystyrene film in the sample beam and record a few of the main bands whose frequency is known and which do not coincide with the main bands in the spectrum

of the sample. The spectrum of bromvalerone calibrated with polystyrene is shown in Fig. 2. The differences between the recorded and correct frequency of the polystyrene bands are then calculated for each region of the spectrum and used in tabular or graphical form to correct the observed band positions of the sample.

Fig. 2. Infra-red spectrum of bromvalerone calibrated with polystyrene.

Interferometric Spectrophotometers

The Fourier transform infra-red spectrophotometer incorporates an interferometer (Fig. 3). Its basic components are a beam splitter and two mirrors, perpendicular to each other, one fixed and one which can be moved backwards and forwards at right angles to its plane. Approximately half of the radiation from the source is reflected to the fixed mirror where it is reflected back to the beam splitter which transmits about half (i.e. a quarter of the original) to the detector. The other half of the original radiation passes through the beam splitter to the movable mirror where it is reflected back to the beam splitter and about half (i.e. a quarter of the original) is reflected to the detector. When the two mirrors are equidistant from the beam splitter, the two beams

Fig. 3. Schematic diagram of the optics of an interferometer.

are said to interfere constructively. When the movable mirror is displaced in either direction by a quarter of a wavelength ($\lambda/4$), the two beams are said to interfere destructively. With monochromatic light, the detector records a beam whose intensity varies as a sine wave as the mirror moves. However, with polychromatic light the detector records the sum of all the sine waves; when both mirrors are equidistant from the beam splitter, all the sine waves are in phase (they interfere constructively) and a strong central peak is recorded in the interferogram. A sample placed in the beam will absorb light of certain wavelengths and therefore the recorded interferogram will be the sum of all the waves except those absorbed by the sample. The interferogram of benzocaine is shown in Fig. 4. This can be transformed mathematically (by the Fourier transform) to give its infra-red spectrum (Fig. 5). For the mid infra-red region, the source is usually

Fig. 4. Interferogram of benzocaine. (Courtesy of Nicolet Instruments Ltd.)

Fig. 5. Infra-red spectrum obtained from the interferogram of benzocaine shown in Fig. 4. (Courtesy of Nicolet Instruments Ltd.)

a Globar operated at about 1500° , and the beam splitter is germanium-coated potassium bromide. The detector is either a pyroelectric bolometer which can be operated at room temperature or a photon detector operating in liquid nitrogen.

Fourier transform infra-red spectrophotometers have a number of advantages over dispersive instruments. Firstly, they can scan quickly (as fast as 10 scans per second), and can therefore be used with gas or liquid chromatography for recording spectra as compounds are eluted. Secondly, all the frequencies are detected simultaneously, rather than sequentially, thus obtaining a much better signal-to-noise ratio and a resultant increase in sensitivity (the Fellgett or Multiplex advantage). Also, the level of stray light is low, typically less than 0.02% transmittance. This means that the absorbance values remain linear beyond three absorbance units. This in turn leads to more accurate quantitative measurements even with strongly absorbing bands.

Data Processing

The use of data-processing equipment in conjunction with infra-red spectrophotometers, both dispersive and interferometric, produces three advantages, namely instrument control, spectrum manipulation, and spectrum identification and interpretation.

Firstly, the control of the instrument is simplified and the reproducibility and accuracy of wavelength and transmission (or absorbance) are greatly enhanced. For example, one commercial Fourier transform instrument uses a helium-neon laser to obtain an accuracy of better than 0.01 cm^{-1} at 4000 cm^{-1} , whereas older dispersive instruments could have an error of 50 cm^{-1} . The accuracy of

the transmittance of Fourier transform instruments is better than 0.1% in the range 0.1 to 100% transmittance.

The infra-red spectrum of a compound represents the variation of absorption, or transmittance, with changing wavenumber. It is customary to present the ordinate of an infra-red spectrum as percent transmittance and most collections of spectra made in the past have been recorded in this way. However, logarithmic conversion to absorbance is now readily achieved and modern instruments usually give a choice for presentation of spectra.

The second advantage, which is based upon the fact that spectra can be recorded in digital form, is the ability to accumulate spectra and to manipulate them. Solvent and impurity spectra can be recorded and subtracted from the sample spectrum, which can then be levelled, smoothed, and converted from transmittance to absorbance or vice versa. The absorbance scale can also be expanded considerably. The spectrum of a weak sample can be scanned repeatedly which, together with averaging of the signal, can reduce noise appreciably. This leads to a dramatic improvement in sensitivity. For example, there is little difference between the spectra of carbon disulphide and of benzocaine in carbon disulphide shown in Fig. 6, but with spectrum manipulation, a good spectrum of benzocaine is readily obtained (Fig. 7). The amount of benzocaine in the cell was approximately 4 μg but only about one quarter of this was in the infra-red

Fig. 6. Infra-red spectra of A, benzocaine in carbon disulphide; B, carbon disulphide; C, the difference spectrum (A – B). (Courtesy of Perkin-Elmer Ltd.)

Fig. 7. The difference spectrum of benzocaine shown in Fig. 6, smoothed, corrected for baseline contribution, and absorbance expanded approximately 200 times. (Courtesy of Perkin-Elmer Ltd.)

beam. Each spectrum was recorded in less than 30 seconds.

The third major advantage afforded by data processing of spectra in digital form is in the identification and interpretation of spectra. The spectrum of a sample can be compared readily with a library of spectra and a list of the compounds of best fit can be either displayed on a screen or printed out. The presence of certain functional groups can also be recorded. These aspects are discussed more fully in later sections.

PURIFICATION OF SAMPLES

It is essential to use pure samples for infra-red spectrophotometry. The main difficulty is that of purifying and handling a few micrograms of material without substantial losses, although these problems have largely been overcome by linking gas or liquid chromatography with Fourier transform spectrophotometry.

This section gives practical advice on the purification of microgram amounts of a sample. It is assumed that the starting material is a residue from the evaporation of a solvent extract of urine, blood,

tissue, or other material. For the toxicologist, the most suitable method of purification is some form of chromatography.

Paper and Thin-layer Chromatography.

Suitable systems for thin-layer chromatography are described on pp. 167 to 177. Any of these systems is potentially useful where it is required to elute a spot, but reversed-phase systems should be avoided because it is difficult to remove the spot without the stationary phase, which would interfere with the infra-red spectrum. Furthermore, location reagents must be chosen with care, and a destructive reagent such as the Marquis reagent for alkaloids, should not be used. Non-destructive reagents such as iodoplatinate solution can be used because the colour complex is decomposable to yield the original compound. However, even this procedure may introduce extraneous peaks into the spectrum and, ideally, location reagents are best avoided. If the compound cannot be detected under ultraviolet light, it could be applied to the paper or thin-layer plate twice and only a portion of the chromatogram sprayed, thus allowing the unsprayed portion to be eluted.

Elution from cellulose thin-layer and paper chromatograms is generally more efficient than from silica gel thin-layer chromatograms; quantitative recoveries from silica gel are rarely attainable. However, thin-layer chromatographic systems produce results more quickly than paper chromatographic systems and will often give better resolution of spots. Thin-layer plates are available with fluorescent additives which facilitate location of spots without altering them chemically. Only experience can determine the best chromatographic system and eluting solvent for any particular compound.

The use of aqueous acid or alkali to elute the compound from the thin-layer plate or paper chromatogram, followed by solvent extraction of the aqueous solution, is more efficient than direct solvent extraction of the adsorbent.

In one method of direct extraction, the adsorbent is scraped from around the spot, the glass adjacent to the spot is carefully cleaned, and the adsorbent is eluted *in situ* directly on to a wall of potassium bromide built around the tip of the spot. The potassium bromide is then pressed into a disk. This technique is only suitable for well-resolved spots. Elution of the spot sideways will reduce contamination from compounds that are not as well resolved. The recovery of material from chromato-

grams varies from nil to over 70%. Compounds containing hydroxyl and carboxyl groups, which can readily form hydrogen bonds with the solid support, tend to be recovered in low yield. Considerable interference in the 1100cm^{-1} region is found with some adsorbents and compounds.

In a variation of this method, the thin-layer adsorbent is placed in the bottom of a glass vessel together with a triangular 'wick' of compressed potassium bromide. Solvent is added and it rises up the wick and evaporates from the upper region. The compound is conveyed up the wick by the solvent and accumulates at the tip of the triangle which is then cut off, dried, and used to prepare a disk. About $10\text{ }\mu\text{g}$ of compound is required to produce a satisfactory spectrum. The advantage of this technique is that the lower part of the potassium bromide wick acts as a filter and removes finely divided adsorbent which can give rise to spurious peaks.

In a further method, the thin-layer adsorbent is scraped onto a small amount of potassium bromide powder in the hub of an 18-gauge metal hypodermic needle. A 1-ml glass syringe is filled with pure solvent and connected to the needle, and the compound is eluted dropwise onto a mound (10 mg) of dry potassium bromide powder. Each drop of solvent is allowed to evaporate completely before the elution of the next drop. The powder and solute are then mixed and pressed into a disk.

Eluted material almost always includes unwanted extraneous matter co-extracted from the paper or thin-layer chromatogram. Thus it is advisable to use the eluent from a 'blank' area as a reference solution. Contamination from plasticisers, solvents, and dirty glassware can also be a serious problem when a spectrum has to be obtained from a few micrograms of a compound. Even momentary contact of dry adsorbent with plastic tubing can remove appreciable quantities of plasticisers. Hence the following precautions should be taken:

(a) use the minimum amount of the purest adsorbent available; (b) elute with less than 1 ml of a solvent containing less than 0.0001% (1 ppm) of nonvolatile residue; (c) keep sample handling to a minimum; (d) clean all glassware with an efficient detergent in an ultrasonic bath; (e) avoid contact of materials and samples with plastics.

Gas Chromatography

Gas chromatography can provide a very convenient method of obtaining pure samples for infra-red spectrophotometry. However, the sample can still

be contaminated with impurities eluted from the stationary phase. The effluent from the chromatograph is a hot vapour and the problem is to obtain small quantities in a form suitable for presentation to the spectrophotometer. The spectrum of the vapour can be recorded directly or the compound can be trapped and then its spectrum recorded. Unfortunately, there is no entirely satisfactory method for the direct coupling of a gas chromatograph to a standard dispersive infra-red spectrophotometer. The outlet of the gas chromatograph can be split and one part connected to a heated cell (or light pipe) placed in the beam of an infra-red spectrophotometer. The gas flow is then stopped, trapping the sample in the cell, and the spectrum is recorded in the vapour phase. This technique can provide acceptable spectra of volatile compounds such as butyl acetate, which has a strong carbonyl band, but spectra of less volatile compounds such as caffeine and phenylbutazone are more difficult to obtain. The temperatures of the connecting pipe and cell are clearly of great importance to keep the compounds as vapours. The coupling of a gas chromatograph to a Fourier transform instrument is much more satisfactory because the speed of scanning is sufficiently rapid to enable the spectrum of a compound to be recorded as it is eluted. Nevertheless, the temperatures of the cell and pipework are still of critical importance. The method used for trapping a compound will depend on whether it is a solid or a liquid and, if the latter, on its volatility. Ways in which small samples can be obtained from a gas chromatograph in a form suitable for presentation to the spectrophotometer are given below.

COOLED TUBES

Most techniques of collecting the effluent employ cooled tubes of glass or metal, but it is difficult to obtain good recoveries of a few micrograms of compounds of differing volatilities by any one technique. Drugs such as barbiturates and phenothiazines can be recovered in 50 to 70% yields in glass or metal capillary tubes held at room temperature, whereas more volatile drugs such as amphetamines require cooling in liquid nitrogen or solid carbon dioxide (A. S. Curry *et al.*, *J. Chromat.*, 1968, 38, 200-208; A. De Leenheer, *J. Chromat.*, 1972, 74, 35-41).

SILVER CHLORIDE MICROCELLS

Microcells extruded from silver chloride and known as 'Extrocells' can be fitted with a silicon rubber serum cap and connected to the outlet of the gas

chromatograph by means of a hypodermic needle. The sample collects in the neck of the cell which is then centrifuged in order to force the sample into the main body of the cell. Solvents can be added if solution spectra are required and are, of course, necessary if the compound is a solid. The cells can be used at room temperature or they can be cooled in freezing mixtures or in liquid nitrogen; they can be used many times provided that they are stored in the dark. The cells are available with path-lengths from 0.1 to 0.01 mm and volumes of 2 to 0.2 μ l. The main disadvantage is that they have to be centrifuged for cleaning as well as for filling and emptying.

MEMBRANE FILTERS

Membrane filters composed of cellulose esters can be used to collect samples. The filters, about 25 μ m thick, are supplied in matched pairs to compensate for their absorption in a double-beam instrument. The filter is placed in a specially designed metal and PTFE holder. The PTFE inlet section reduces condensation of the effluent before it reaches the filter and the metal outlet section allows the filter to be cooled. The filter holder is connected to the outlet of the chromatograph by a Luer fitting just before the sample emerges. When the sample has been collected, the filter is removed and placed in the spectrophotometer. The method is simple and easy to use and is capable of giving extremely good results.

ALKALI HALIDE TUBES

A straight tube containing a plug of powdered alkali halide is connected to the outlet of the chromatograph. The effluent condenses on the halide which can then be pressed into a disk. This technique is most useful for compounds which are solid at room temperature.

The main difficulty, common to all these methods of collecting fractions, is to determine the optimum temperature of the outlet tube from the chromatograph and the temperature of the collecting device. This problem can only be solved by trial and error.

High Pressure Liquid Chromatography

High pressure liquid chromatography provides a very convenient method of purification, particularly where gas chromatography is either inapplicable or where derivatisation of the compound is necessary. Unlike gas chromatographs, liquid chromatographs are usually operated at or slightly above ambient temperature, and most types of detector

are non-destructive. Thus, the appropriate fraction of eluate can be collected by holding a test-tube under the exit port.

The method used to retrieve the sample from the eluate for presentation to the spectrophotometer will depend upon whether the compound is a solid or a liquid and, if the latter, on its volatility as well as the quantity present. All the common solvents absorb in the infra-red region. However, with the data processing facilities of modern infra-red spectrophotometers, this is not a great disadvantage. The spectrum of the solvent can be recorded and then subtracted from the combined spectra of the compound and solvent to give a difference spectrum. If the concentration of the sample is low, the difference spectrum can be enhanced either by repetitive scanning and signal averaging or by expansion of the ordinate scale (see Figs 6 and 7). In many cases, however, the amount of material will be too small to enable the compound to be collected and transferred to standard cells. The use of microcells such as 'Extrocells' may be advantageous. Alternatively, the compound can be recovered by evaporation of the solvent. However, evaporation will also concentrate any non-volatile impurities in the solvent and the use of pure solvents is essential. Another possible source of contamination is the packing material used in liquid chromatography columns. Many of these materials are based on silica gel and appreciable amounts of silica may be dissolved by certain solvents.

Microsublimation

This simple technique can be highly effective in purifying certain compounds (Fig. 8). Drugs may be sublimed from an evaporated solvent extract in the tube on to the cold finger of the apparatus, and the sublimate transferred by grinding the potassium bromide powder gently with the cold finger.

SAMPLE PREPARATION

Infra-red spectra can be determined in the vapour, liquid, and solid phases, but most compounds of interest to the toxicologist are solid at room temperature and the determination of spectra in this phase has been used most widely. However, it is all too easy to rush for the potassium bromide and prepare a disk, and to forget some of the problems that may arise with this technique. The advantages of determining the spectrum of a solid as a solution in a suitable solvent should not be overlooked.

Fig. 8. Apparatus for microsublimation.

The physical state of a drug may have a marked effect on its infra-red spectrum and a suggested hierarchy of sample preparation procedures for liquids is: (1) solution; (2) if insoluble, undiluted in a thin cell; (3) liquid film between salt plates. For solids: (1) solution; (2) mineral-oil mull; (3) potassium bromide disk; (4) pyrolysate.

An infra-red spectrum can be obtained from as little as 1 μg or less of a compound, but greater sensitivity is obtained by placing the maximum number of molecules of the sample in the infra-red beam. Thus, where the amount of sample is limited, the area of the infra-red beam must be reduced by using a beam condenser and expanding the transmittance scale.

Gases

Infra-red spectra in the vapour phase are rarely determined with dispersive spectrophotometers unless the substance is a gas at room temperature. Special long-path, airtight gas cells are required. The technique has become more widely used with the advent of Fourier transform infra-red spectrophotometers coupled directly to gas chromatographs.

Liquids and Solutions

A wide range of types of cell is available for determining the spectra in the liquid phase. These cells usually consist of two parallel transparent

windows (0.1 to 0.01 mm apart) separated by a spacing gasket and fitted with inlet and outlet ports. Variable path-length cells are also available, in which one window on a piston moves in relation to the other window. These cells are particularly useful for concentrated solutions since the solvent can be placed in the reference beam of the spectrophotometer and the solvent peaks neutralised. Spectra of viscous non-volatile liquids can also be determined by sandwiching a thin film between two alkali halide plates.

The number of suitable solvents is limited and the most widely used are carbon tetrachloride and carbon disulphide because they have relatively few absorption bands in the infra-red region. Other solvents which may be used include chloroform, ethylene dichloride, methylene chloride, benzene, cyclohexane, and heptane. The concentration of the compound is usually about 5 to 10%, but concentrations up to 20% w/v can be employed. With these high concentrations, hydroxyl and amino compounds often exhibit bands due to intermolecular hydrogen bonding.

A disadvantage of this method is that interactions between the compound and the solvent can occur. This may result in quite considerable changes in the frequency of certain bands in different solvents. Also, the heat of infra-red radiation can cause evaporation of volatile solvents to give changes in concentrations.

Solids

Solids are generally examined either as thin films or as dispersions in either liquids or solids, since finely packed solids scatter infra-red radiation.

MULLS

Solid compounds are dispersed in a liquid, e.g. liquid paraffin (Nujol). The finely powdered compound (about 0.2 mg) is mixed with one drop of the liquid and ground in an agate mortar. Sufficient liquid is then added so that the final mull is the consistency of a thin cream. The mull is spread on an alkali halide plate, usually sodium chloride or potassium bromide, and another plate placed on top, taking care to exclude air bubbles. A disadvantage of this method is that the spectrum of the liquid will be superimposed upon that of the sample. Consequently, liquid paraffin cannot be used if the carbon-hydrogen stretching frequencies are to be examined and a halogenated liquid such as Fluorolube[®] (a fluorinated hydrocarbon) or hexa-chlorobutadiene must be employed. Changes in polymorphic forms

and consequent changes in spectra may occur with this method.

ALKALI HALIDE DISKS

The technique of dispersing the compound in an alkali halide has been used widely in the identification of drugs. Originally, potassium bromide was used and the technique is still often referred to as the 'KBr technique'. However, potassium chloride is superior to potassium bromide because it is less hygroscopic. The finely powdered dry compound (about 1 mg) is mixed with the alkali halide (about 250 mg), ground either mechanically in an agate ball mill or by hand in an agate mortar, and pressed into a thin disk. If the sample is insufficiently ground, asymmetrical bands may be formed which vary in position and intensity from the accepted values (the Christiansen effect) and may give the impression of impurities in the sample. If only small quantities of the compound are available (about 200 µg), a thin cardboard mask with a slot in the centre can be used. The mask is placed in the die and the slot filled with the mixture before pressing. A mask is often employed routinely because it provides a support for the alkali halide and so enables the disk to be handled more easily. Microdisks of diameter down to 0.5 mm can be prepared by using metal (lead or stainless steel) disks of 13 mm diameter with the appropriate size hole in the centre. The hole is filled with potassium bromide (about 1 mg) containing from 0.05 to 0.2% of the sample, which is then pressed in the usual way. The metal disks should be washed before use in both polar and non-polar solvents and finally in good quality acetone to remove traces of oil and grease, which may produce artefacts in the C—H region of the spectrum. The method may fail if excessive pressure is used, causing deformation of the lead disk.

Another useful technique consists of dissolving the compound in a small volume of chloroform and drawing it into a Hamilton-type syringe held in a repeater holder. A small cluster of fine potassium bromide particles is picked up on the end of the needle by a trace of chloroform expressed from the needle. The solvent is evaporated under a table lamp and the rest of the solution is fed into the potassium bromide from the syringe as it evaporates. A disk is then made from the powder. It is important that the end of the needle is cut at right angles to the shaft and ground flat; those supplied for use with liquid chromatographs are suitable. For bases one must decide whether to evaporate solvents without

the addition of hydrochloric acid, and accept the consequent loss of certain amines by volatilisation, or to add hydrochloric acid and accept the reduced solubility of the amine hydro-chlorides in chloroform. Considerable losses of the sample by evaporation may occur for other types of compound (e.g. phenols), particularly when dilute solutions are used. It is essential to use dry hydrophobic solvents, since water can cause artefacts in the spectra, particularly when scale expansion is used.

Because potassium bromide is hygroscopic and it is sometimes difficult to remove the last trace of water, silver chloride may be used instead. An indentation about 0.8 mm deep and slightly wider is made in the centre of a small piece of silver chloride sheet, and a solution (about 0.1 μ l) containing as little as 500 ng of substance is placed in the indentation and gently warmed to evaporate the solvent. The sheet is then placed in a die which produces a cone of silver chloride with the sample embedded in it. A similar cone of plain silver chloride is mounted in the reference beam. Excellent spectra can be obtained with this technique.

The alkali halide disks can be stored in cellophane envelopes and give good spectra several years after preparation. A well-prepared disk should have over 80% transmittance in regions where the sample does not absorb, although it will not necessarily be visually clear. It is not always easy to obtain a good disk when a very small amount of a recovered drug is available. In these circumstances, attenuation of the reference beam can 'sharpen' the spectrum. Another technique is to heat the alkali halide disk to about 80° for 30 to 60 minutes with an infra-red lamp to evaporate any absorbed water. However, the high temperature accentuates the disadvantages of the alkali halide disk technique. In addition, the following artefacts have been observed: (i) formation of anhydrides from carboxylic acids, (ii) ketals and cyanohydrins reverting to the parent ketone, and (iii) loss of water from secondary alcohols.

There are several disadvantages inherent in the alkali halide disk technique. The alkali halides which are generally used are hygroscopic and it is very difficult to exclude all traces of water. This often results in a hydroxyl band in the spectrum. A number of compounds containing hydroxyl groups either form hydrogen bonds with the alkali halide or are adsorbed on its surface, so the method is unsuitable if the hydroxyl band is to be examined. In such cases, polytetrafluoroethylene (PTFE) powder can sometimes be used in place of the alkali

halide. Polymorphism occurs in many compounds and the grinding and pressing can alter the crystal form and consequently the spectrum. Splitting of bands also frequently occurs. Another disadvantage is the possibility of chemical changes occurring during the preparation of the disk. For example, double decomposition can occur:

Hence, hydrochlorides should preferably be examined in potassium chloride. Bromide may be oxidised to bromine by some compounds, particularly strong oxidising agents, and this may lead to a disk becoming either discoloured or having yellow-brown spots.

If the sample is a potential oxidising agent, other techniques of sample preparation should also be used in order to check the reliability of the spectra obtained from the alkali disk.

Organic compounds that contain nitrogen in a functional group should not be used with plates which are made of thallium bromide and thallium iodide (KRS-5 plates) as they appear to react with the plates. Despite these disadvantages, the technique is still a most useful one for solid drugs. The advantages are that, besides being easy to use, the absorption of the alkali halide is very low and the quantity of compound required is small. The disks can easily be stored for reference purposes or the compound can be recovered if required.

THIN FILMS

This method is of use where it is necessary to obtain spectra free from dispersing media. The film can be prepared either by melting the solid and pouring it on to a suitable surface or by evaporation of a solution. This method is not widely used.

ATTENUATED TOTAL REFLECTANCE

This method can be used to identify solid drugs but is only of use where relatively large amounts of compounds are available. The finely-ground sample is spread as a thin layer onto the sticky side of a piece of self-adhesive tape, and the tape is placed against the reflecting surface of the instrument with the sample side in contact. Sufficient sample is required to cover the surface of the tape completely, otherwise the spectrum of the tape will be recorded in addition to that of the sample. The technique is of use when the acid and salt forms need to be differentiated.

IDENTIFICATION OF SPECTRA

In recent years, much work has been devoted to the identification and interpretation of infra-red spectra by computer. Collections of spectra on paper can be converted into a numerical form (digitised) and recorded on a disk or tape, and many modern infra-red spectrophotometers record the spectra directly in digital form. The use of a data station coupled to an infra-red spectrophotometer enables the spectrum to be matched automatically against those in the library collection, and the names of compounds giving the closest fit displayed. An indication of the closeness of fit may also be given. It is important that the identification is checked by a careful comparison of the spectrum with a printed copy of that of the compound(s) indicated.

With some data systems the spectrum retrieved from the library can be displayed at the same time as that of the sample and the two spectra may even be superimposed, so allowing easy comparison and the identification of any differences.

The method employed to identify the spectrum will depend very largely on how much other information about the compound is already available, e.g. *R_f* values and colour reactions. If the identity of the compound is suspected, the spectrum should be compared with that obtained from an authentic sample of the substance.

If this procedure fails and in cases where the type of compound is unknown or can only be allocated to a certain class, e.g. a phenothiazine or a barbiturate, then reference may be made to the

Fig. 9. Infra-red spectra of A, amphetamine base; B, amphetamine hydrochloride; C, amphetamine mandelate; D, amphetamine sulphate.

index of Infra-red Peaks in Part 3 and to the information in the individual monographs. Comparison of the spectrum of the unknown with that of the suspected compound should either confirm or disprove the tentative identification. If the two spectra have been recorded under similar conditions on the same type of instrument then they should be very similar in appearance. If the spectra have been recorded on different instruments then they may, superficially at least, appear very different. In this case a more detailed study of band frequencies and relative intensities must be undertaken.

It must also be remembered that different forms of the same compound will give different infra-red spectra. For example, the spectra for amphetamine base and the hydrochloride have many similarities, but the hydrochloride spectrum shows much finer detail (Figs 9A and 9B). Also the spectra for the hydrochloride and mandelate salts show differences (Figs 9B and 9C) due to the absorption of the mandelic acid. However, the spectra of the hydrochloride and sulphate (Figs. 9B and 9D) are very similar since they are both inorganic salts, the only major difference being the absorption band due to the sulphate at 1110 cm^{-1} .

If the spectrum does not agree with any of the available spectra and the type of compound is known, then the appropriate collections of spectra can be consulted.

Spurious bands can occur readily in infra-red spectra, particularly when a biological sample has undergone several purification procedures. Traces of plasticisers, surfactants, and oils left on glassware can all give rise to artefacts; some spurious infrared bands are given below (after H. A. Szymanski, *A Systematic Approach to the Interpretation of Infrared Spectra*, Buffalo, New York, Hertillon Press, 1971).

Wavenumber cm^{-1}	Assignment	Comments
3800–2500	H_2O	Bound or unbound water in a molecule can give rise to sharp or broad bands. In alkali halide disks a water band at 3350 cm^{-1} may appear
3300–3000	NH_3^+	Lens tissues
1810–1600	C=O	Impurities containing the carbonyl group, e.g. phosgene in chloroform, plasticisers
1750–1500	H_2O	Bound or unbound water can give rise to sharp or broad bands
1610–1515	COO^-	Alkali salts (which also have a weaker band at 1425 cm^{-1}) can be produced from alkali halides
1400	NH_3^+	Lens tissues

Wavenumber	Assignment	Comments
1265	Si-CH_3	Stopcock grease or silicone oil
1110–1050	Si-O-Si	Glass or hydrolysed Si compounds
730 & 720	Polyethylene	Polyethylene laboratory ware
700	Polystyrene	Polystyrene laboratory ware

The final stage in the process of identification is, ideally, the comparison of the spectrum of the unknown with that of the pure drug obtained under as near identical conditions as possible and on the same instrument. This is particularly important where the identity of the spectrum has been determined automatically. The data station can only select spectra that are in its library and if the spectrum of the compound under investigation is absent, then it will select those giving the next best fit.

INTERPRETATION OF SPECTRA

When a suitable fit for an identity cannot be obtained for a spectrum, it must be interpreted from first principles.

Most types of functional group exhibit absorption bands in particular regions of the spectrum. For example, the hydroxyl groups of alcohols, phenols, and acids exhibit an O-H stretching band in the region from 3700 to 2500 cm^{-1} . The carbonyl groups of ketones, aldehydes, acids, and esters exhibit a C=O stretching band in the region from 1870 to 1535 cm^{-1} . The precise location of the band will often give an indication of the structural environment of the group. The correlation of frequency with functional groups is discussed in detail by L. J. Bellamy (1975).

The approach to the interpretation of the infra-red spectrum of an unknown drug is illustrated by reference to the barbiturates. These are derivatives of malonylurea (barbituric acid) and all of them have two substituents at position 5. In addition, some of them are also substituted at position 1 and in others the oxygen atom attached to position 2 is replaced by sulphur to form thiobarbiturates.

The barbiturates can be classified chemically into three classes: 5,5-disubstituted barbituric acids, 1,5,5-trisubstituted barbituric acids, and 5,5-disubstituted thiobarbituric acids.

These classes can be further divided depending on whether the substituents in position 5 are alkyl, alkenyl, aryl, or cycloalkenyl. In most common barbiturates, one of the 5-substituents is either ethyl or allyl and the other is either a straight- or branched-chain alkyl or alkenyl group with five or fewer carbon atoms. Some barbiturates are marketed as sodium salts. The infra-red spectrum of a barbiturate will therefore depend on the class of compound, the nature of the substituents, and whether it is the free acid or the sodium salt.

The various polymorphs of a compound often exhibit different infra-red spectra. Among drugs, the barbiturates are most notable for the extent to which they exhibit polymorphism, including many metastable forms found only in mixtures. Spectral differences between polymorphs are associated with different types of hydrogen bonding, and there is a correlation between hydrogen bond strength and duration of action of the barbiturates on the central nervous system. The crystalline structure of barbiturates can be affected by grinding with an alkali halide or in preparing a mull, but if precautions are taken to ensure reproducibility, the spectra of the barbiturates are sufficiently different to be used for identification purposes.

With the exception of phenobarbitone and barbituric acid, the free barbiturates do not absorb appreciably above 3300 cm^{-1} (e.g. barbitone, Fig. 10A), a feature which distinguishes them from the ureides; a weak band of unknown origin occurs sometimes between 3500 and 3400 cm^{-1} . All the barbiturates have two bands which occur near 3200 and 3100 cm^{-1} and are due to N—H stretching vibrations. In the 5,5-disubstituted compounds, the relative intensity of the two bands is similar although that at 3100 cm^{-1} is usually slightly less intense. In compounds substituted on the nitrogen atom at position 1, the intensity of the band at 3100 cm^{-1} may be greatly reduced and is often present only as a shoulder on the band at 3200 cm^{-1} , e.g. metharbitone. Methylphenobarb-itone appears to be an exception in that the band at 3100 cm^{-1} is the most intense one in the region. A similar phenomenon occurs with the sodium salts since here again one of the hydrogen atoms in either position 1 or 3 has been replaced.

A series of up to four medium to intense bands occurs in the region 3000 to 2800 cm^{-1} , and is due to alkyl C—H stretching vibrations of the substituents in positions 1 and 5. The intensity of the bands gives a

Fig. 10. Infra-red spectra of A, barbitone and B, barbitone sodium.

very approximate indication of the number of C—H bonds and hence the number of carbon atoms in the chain. This does not appear to apply to the sodium salts, in which the band occurring at 3000 to 2950 cm^{-1} is usually increased in intensity, compared to that of the free acid, and becomes the strongest band. Compare, for example, the spectra of barbitone (Fig. 10A) and barbitone sodium (Fig. 10B).

The barbiturates have up to three strongly absorbing bands in the region 1765 to 1670 cm^{-1} which are due to C=O stretching vibrations. A knowledge of the origin of these bands is useful in helping to understand the differences in the spectra of the various types of barbiturate.

In symmetrical molecules, the three bands are all of similar intensity. In asymmetrical molecules, the band at the highest frequency is often less intense than the other two, and this is particularly so when the molecule is substituted in position 1. The sodium salts of the barbiturates have only two bands in this region, since the molecule is no longer symmetrical, and these occur at a lower frequency, between 1700 and 1650 cm^{-1} . In addition, a broad strongly absorbing band occurs between 1600 and 1550 cm^{-1} ; the free barbiturates show practically no absorption in this region. The sodium salts of the thiobarbiturates

exhibit only the lowest of the three C=O vibrations in the region 1700 to 1680cm⁻¹. They do, however, exhibit the broad, strongly absorbing band which occurs between 1650 and 1600cm⁻¹. Therefore, the number, position and intensity of the bands between 1800 and 1500cm⁻¹ give a very good indication of whether the barbiturate is the free acid, the salt, or a thiobarbiturate.

Most barbiturates have a number of strongly absorbing bands between 1460 and 1250 cm⁻¹, and some of these are due to C—H deformation and C—N stretching vibrations. The sodium salts of the thiobarbiturates have a broad strongly absorbing band between 1500 and 1480cm⁻¹ which is believed to be due to C—N stretching vibrations of the carbon atom attached to sulphur. This band is not present in the ordinary barbiturates and therefore provides another means of distinguishing those containing sulphur. Many barbiturates exhibit a few weak to medium intensity absorption bands in the region 1150 to 900cm⁻¹. The 1-substituted barbiturates exhibit a greater number of sharp bands of medium intensity. Those compounds which contain an allyl group exhibit bands at about 1000 to 960 cm⁻¹ which are due probably to C—H deformation vibrations. The sodium salts of the thiobarbiturates show a band of medium intensity between 1020 and 1000cm⁻¹. Finally, many barbiturates, but not the thiobarbiturates, exhibit a broad band of medium to strong intensity between 900 and 800 cm⁻¹.

Infra-red Data in Monographs

It has been shown (A. S. Curry *et al.*, *J. Pharm. Pharmac.*, 1969, 27, 224-231; P. H. B. Ingle and D. W. Mathieson, *Pharm. J.*, 1976, 216, 73) that an infra-red spectrum of a particular substance can be retrieved from a collection, with some degree of confidence, by reference to its six major absorption bands. This forms the basis for a system of identification.

Data consisting of six major absorption bands which have been selected from the recorded spectrum over the range 2000 to 650cm⁻¹ (5 to 15 μm) are included in the monographs in Part 2. In many cases, the spectrum is also reproduced in a reduced size. The selected peaks are the six most intense peaks, except that peaks in the region where Nujol absorbs (1490 to 1320 cm⁻¹, 6.7 to 7.6 μm) have been omitted. The peaks are arranged in descending order of amplitude. It should be noted that, because of variations in instruments and conditions, other determinations of the spectrum may not give peaks with the same

relative intensities.

All the spectra are included in the index of Infrared Peaks in Part 3. Details of how to use the infrared data are given in the index.

Published Spectra

GENERAL COLLECTIONS

Sadtler Collection. The most comprehensive collection of published spectra is that of the Sadtler Research Laboratories. In the solid and liquid phases, over 63 000 spectra of pure compounds including 600 spectra of commonly abused drugs, 600 spectra of prepared drugs, 1200 spectra of pharmaceuticals, 750 spectra of steroids, and 700 spectra of toxic chemicals have been published, in addition to 36 000 spectra of commercial products. There are also 7400 spectra in the vapour phase. Many are, or will be, available in numerical form so that they can be searched automatically by an appropriate Fourier transform spectrophotometer.

Chemical Rubber Company Collection. An atlas of 12000 spectra: J. G. Grasselli and W. M. Ritchey, *CRC Atlas of Spectral Data and Physical Constants/or Organic Compounds*, 2nd Edn, Cleveland, USA, CRC Press Inc. 1975.

Mass Spectrometry

R. E. Ardrey

Mass Spectrometry is concerned with the electron ionisation and subsequent fragmentation of molecules, and with the determination of the mass to charge ratios (m/z) and the relative abundances of the ions which are produced. Functional groups in the molecule direct the fragmentation in such a way that, knowing the structure of the molecule, it is possible to predict the fragmentation pattern. Conversely, knowing the fragmentation pattern, a plausible structure of the original molecule can often be suggested. In addition, the technique allows the molecular weight to be determined and this is probably the most important piece of information available from a mass spectrum. If the appropriate spectrometer is available a unique formula may be obtained.

The advantage of mass Spectrometry over other commonly used analytical techniques lies in the wide range of samples that may be examined and the amount of information that may be obtained. In many cases a single mass spectrum allows an unambiguous identification to be made. The sensitivity and specificity of the technique allow minor components of mixtures to be quantified down to the picogram level. The main disadvantages lie in its complexity and cost. The interrelationship of the component electronic modules makes faultfinding an expert task and the best results are usually obtained by having an operator dedicated to the operation and maintenance of the instrument. This is not quite so important in the case of bench-top machines which are designed for multi-operator use and are more easily maintained.

A mass spectrometer may be very costly depending on the facilities available and the data handling which is provided. Taking into account depreciation, maintenance, spares, etc., the minimum operating cost (1985) is around £25 per hour. As it is possible to analyse only about 6 solid samples (or 2 or 3 samples from a gas chromatographic column) per hour, the technique is fairly expensive. This must be equated with the results that may be obtained and therefore mass Spectrometry should not be used for routine analyses that can be carried out using less costly techniques.

Mass Spectrometry, either alone or in combination with a chromatographic separation, is probably the most effective method for the identification of drugs and their metabolites. The specificity and sensitivity of the technique allow a full mass spectrum, and, in many cases, an unambiguous identification to be obtained from less than 50 ng of material. Quantitative measurements can be carried out at the picogram or even femtogram levels. The limit of detection is governed by the level of the background spectrum obtained rather than by the inherent sensitivity of the technique. Theoretical calculations show that 20 pg of material entering the ion source of a mass spectrometer is sufficient to enable a full spectrum to be obtained and this has been demonstrated. Similar calculations show that quantification should be possible down to the 1 fg level.

INSTRUMENTATION

A mass spectrometer may be conveniently divided into five basic components: sample inlet system, ionisation, ion separation, ion detection and amplification, and presentation of results (Fig. 1).

Fig. 1. Schematic diagram of a mass spectrometer.

Sample Inlet System

The interior of a mass spectrometer is under high vacuum (10^{-6} torr) in order to minimise the number of collisions undergone by ions and thereby maximise the number of ions reaching the detector. Sample inlet systems must enable the sample to be introduced without loss of the vacuum and must be capable of handling samples as gases, liquids, or solids, either as single components or as multi-component mixtures.

For solids, a direct insertion probe is used. The sample, either as a solid or as a solution in a volatile

solvent, is placed in a small glass crucible at the end of the probe. The whole probe assembly is then inserted through a vacuum lock and positioned close to the ion source. The sample is vaporised directly into the ion beam, either by the heat associated with the source or by external heating. Thermal decomposition may take place; for example, methyprylone (molecular weight 183) decomposes in the ion source of the mass spectrometer at 200°, producing the spectrum shown in Fig. 2A. If the source temperature is approximately 150° the true spectrum is obtained (Fig. 2B). In some cases the sample vapour pressure cannot reach 10^{-6} torr and conversion to a more volatile chemical derivative is necessary.

Fig. 2. Mass spectrum obtained by probe analysis of methyprylone, molecular weight 183, with mass spectrometer source at A, 200° and B, 150°.

Mixtures of solids of different volatilities may be analysed using the probe. By gently increasing the temperature of the probe, the pure spectrum of the component of higher volatility is first obtained; as the temperature is slowly increased, the more volatile component distils off and the spectrum of the less volatile component appears. This technique can sometimes be utilised in the analysis of materials eluted in thin-layer or paper chromatography to reduce the effect of the background spectrum. The probe allows rapid analysis but this must be balanced against the possibility of interference from the background spectrum and/or thermal decomposition making the spectrum difficult to interpret.

Gases and volatile liquids may be studied by using a heated evacuated vessel. This is linked to the ion source usually by a glass capillary which allows the sample to enter the source at a constant rate.

Mixtures are best studied by the combination of mass spectrometry with a chromatographic separation. This may be by paper or thin-layer chromatography, but more importantly, by the direct linking of gas chromatography or high pressure liquid chromatography with the mass spectrometer (GC-MS and HPLC-MS).

INTERFACES FOR GAS CHROMATOGRAPHY

Two types of gas chromatographic column, capillary and packed, are in routine use (see page 178). However, the width of the chromatographic peak places limitations on the performance of the mass spectrometer, and the difference in flow rates affects the way in which each type of column must be interfaced to the mass spectrometer.

Capillary columns operate at carrier gas flow rates of about 1 to 2 ml/min and the mass spectrometer can accept all the effluent from the column without loss of performance. Packed columns operate at much greater flow rates (around 30 ml/min) and in order to maintain the vacuum an enriching device, or separator, must be used to prevent all of the effluent entering the ion source. Three types of separator are in common use and each relies on the difference in physical properties of the carrier gas and the sample.

Jet Separator

This is available in two forms, the single-stage or the two-stage jet. The single-stage jet separator consists of a series of aligned orifices, the gap between the orifices being evacuated by a rotary pump (10^{-2} torr). As the effluent from the chromatographic column passes through the first orifice the lighter molecules of carrier gas (usually helium) have less momentum and tend to diverge and are pumped away. Those with higher momentum have less opportunity to spread out and so pass into the next orifice. The two-stage jet separator consists of two single-stage separators in series, the volume around the second set of orifices being evacuated with a diffusion pump. The separator is usually constructed of glass or stainless steel to minimise decomposition of the sample and is kept at a suitably high temperature to prevent condensation of less volatile organic components.

The efficiency of this device depends on several factors, (i) The molecular weight of the carrier gas should be as low as possible and helium, molecular weight 4, is preferred. This is especially important if the carrier gas is being used as a reagent gas for chemical ionisation and a compromise between chemical ionisation and separator efficiency has

sometimes to be reached, (ii) The physical dimensions of the jets and the gap(s) between them are critical because if the gap is too great, sample molecules are pumped away, while if the gap is too small, the amount of carrier gas removed is reduced. (iii) The optimum carrier gas flow rate is related to the dimensions of the separator, and the relationship should be determined experimentally for each particular interface.

Membrane Separator

This separator relies on the fact that the conductance of a silicone rubber film, a few micrometres thick, is several orders of magnitude greater for organic molecules than for the carrier gas. The column effluent is passed over this membrane, the other side of which is directly attached to the ion source of the mass spectrometer, which is at high vacuum. Transfer of sample occurs with high efficiency.

Glass Frit Separator

The chromatographic column is connected to the ion source of the mass spectrometer by means of a porous tube, the outside of which is maintained at low pressure. The smaller molecules of carrier gas diffuse through the porous tube and are pumped away whilst the enriched stream of sample molecules passes into the mass spectrometer.

The relative performance of particular examples of these devices will depend on many instrumental features but a comparison of their characteristics is given below.

Interface	Proportion transferred	Temperature limitations	Lag time
Single-stage jet	about 40%	350°	none
Two-stage jet	up to 60%	350°	none
Membrane	up to 95%	250°	noticeable
Glass frit	about 50%	350°	negligible

INTERFACES FOR HIGH PRESSURE LIQUID CHROMATOGRAPHY

The use of high pressure liquid chromatography enables many compounds to be studied which are not amenable to gas chromatographic analysis, for example those that are thermally labile. Eluent flow rates of between 0.5 and 2.0 ml/min are commonly used, whilst the maximum input the mass spectrometer can accommodate is about 1 to 4 ml/min of gas at standard temperature and pressure (s.t.p.). Simple calculations show that 1 ml of liquid hexane gives 172 ml of gas at s.t.p., 1 ml of chloroform gives 285 ml, 1 ml of methanol 550 ml, and 1 ml of water 1200 ml. In the low pressure

environment of the mass spectrometer ion source these volumes are much greater. The problems of maintaining a satisfactory vacuum when interfacing a high pressure liquid chromatograph with a mass spectrometer are therefore much greater than those associated with a gas chromatography interface.

There are three possible ways of making high pressure liquid chromatography compatible with mass spectrometry. They are increasing the pumping capability of the mass spectrometer, reducing the flow through the chromatographic column, and developing an interface.

The first method imposes too many limitations on the system to make it viable in practice, while low-flow high pressure liquid chromatography is still being developed and has only been reported for the separation of mixtures of pure compounds.

Two types of interface are available, one of which uses direct liquid insertion and the other uses a moving belt. In the *direct liquid insertion interface*, the total effluent from the column passes through the interface and past a pinhole orifice adjacent to the ion source of the mass spectrometer; the size of the orifice can be altered. A small volume of effluent passes through the pinhole and into the mass spectrometer. Coolant must be provided to prevent vaporisation of the solvent which would otherwise increase the ion source pressure to an unacceptable level. When electron impact mass spectra are required, the ion source pressure must be low and, therefore, only 0.1% of the effluent can be allowed into the source. Chemical ionisation allows a much larger proportion of the effluent to be used (up to 10%) and hence the use of this interface is restricted, on the grounds of sensitivity, to chemical ionisation only. The main disadvantages of the direct liquid insertion interface are that pre-evaporation of sample in the interface degrades chromatographic performance and that the very small orifice tends to become blocked.

In the *moving belt interface*, effluent from the column is brought into contact with the belt, and the film of effluent is carried under an infra-red lamp evaporator which rapidly removes most of the solvent. The solute and residual solvent then pass through two vacuum locks, where remaining solvent is removed, and into the ion source of the mass spectrometer where the sample is flash vaporised. The belt then travels over a clean-up heater which removes any residual solute.

The solvent capacity of this system ranges from about 0.2 ml/min for solutions containing large amounts

of water, e.g. water: methanol (90:10), to about 1.5 ml/min for volatile non-polar solvents. If solutions with a large proportion of water are used, the solvent tends to form droplets on the belt rather than an even film. This leads to distortion of the mass spectra, but this may be alleviated by dropping a small amount of detergent or alcohol on to the belt just before the application of the column effluent. An alternative approach is the use of post-column liquid/liquid extraction to remove the aqueous phase and this can give 99% separation.

The advantage of the belt interface is that it may be used to obtain electron impact spectra, although in practice the background spectrum renders the low mass range ($m/z < 100$) useless for interpretation purposes. This background is even greater if volatile buffers are used in the chromatographic system. Non-volatile buffers or ion-pair reagents tend to be deposited on the belt impairing the performance of the interface and are normally removed by use of a belt wiper. The belt interface also tends to degrade the column performance slightly.

Ionisation

The most widely used method of ionisation is by *electron impact* (EI) in which the vaporised sample molecules are bombarded with a stream of high energy electrons. Usually, electrons of 70 eV energy are used although only 10 eV is required for ionisation. The excess energy absorbed (up to 10 eV) causes fragmentation of the molecule to produce both negative and positive ions.

POSITIVE IONS

The simplest process which may initially occur is the removal of a single electron from the intact molecule to give the positively charged 'molecular ion'. The abundance of this molecular ion varies according to the structure concerned. For example, lysergide (mol. wt 323) contains a stable ring structure and the molecular ion is the most intense ion (Fig. 3) whereas it is totally absent in the spectrum of amphetamine (mol. wt 135) in which a

Fig. 3. Electron impact mass spectrum of lysergide, molecular weight 323.

Fig. 4. Electron impact (A) and chemical ionisation (B) mass spectra of amphetamine.

very labile bond exists (Fig. 4A). The molecular ion may rearrange and/or fragment into ions of lower mass to charge ratio (m/z) which may fragment further.

The very short-lived ions ($< 10^{-6}$ s) will decompose in the source of the mass spectrometer and will not be detected as such, while long-lived ions ($> 10^{-5}$ s) are accelerated through the mass spectrometer to reach the detector intact. The ions of intermediate lifetime (10^{-5} to 10^{-6}) are accelerated from the source with mass m_1 but before reaching the mass analyser decompose to give a smaller ion of mass m_2 . In the case of a magnetic sector instrument a broad 'metastable ion' peak (m^*) is observed at a non-integral m/z value given by the relationship

$$m^* = \frac{(m_2)^2}{m_1}$$

for $m_1^+ \rightarrow m_2^+ + m$ (neutral)

These ions are of diagnostic use, for their presence shows that a certain fragmentation occurs although their absence does not necessarily signify that it does not.

The most important piece of information which may be obtained from a mass spectrum is the molecular weight. However, certain classes of compounds do not show molecular ions and in other cases it is not always possible to identify unequivocally the molecular ion. Therefore a family of so called 'soft ionisation' techniques has been developed. These generate a molecular ion or 'quasi-molecular ion' and fragmentation is kept to a minimum. The most commonly used technique is *chemical ionisation* (CI)

in which the sample is mixed with a large excess of a reagent gas such as isobutane or methane. The mixture is then bombarded with high energy electrons, as in electron impact ionisation. The reagent gas undergoes preferential ionisation and the primary ions so produced react with further reagent gas molecules to produce a number of chemically reactive species such as CH_5^+ and C_2H_5^+ in the case of methane, and C_4H_9^+ in the case of isobutane. These secondary ions subsequently react with the sample molecules to produce new ions predominantly with a mass one greater than the molecular weight by transfer of a proton. Usually, few fragmentation/rearrangement ions are observed and this quasi-molecular ion is the most intense ion in the spectrum (base peak). Fig. 4 shows the electron impact and chemical ionisation spectra of amphetamine.

An alternative method which may be used to depress fragmentation and enhance the molecular ion is to reduce the energy of the bombarding electron beam from 70 eV to a value just above the so-called 'appearance potential' of the molecular ion. In this case, sufficient energy is available to ionise the molecule, but not to cause fragmentation. This technique suffers from a very low sensitivity and in many cases still does not give a recognisable molecular ion.

Electron impact and chemical ionisation are complementary techniques and it is possible to obtain instrumentation which allows spectra of both types to be collected alternately throughout lengthy analyses, thus providing both molecular weight and fragmentation information from a single determination. For qualitative work this approach is adequate, but more critical conditions are required to obtain the best and most consistent performance from chemical ionisation, and it is recommended that a spectrometer is devoted solely to the production of chemical ionisation spectra. Continued use of chemical ionisation also contaminates the source and reduces electron impact performance. Under normal circumstances chemical ionisation is slightly less sensitive than electron impact although this does depend on the material under consideration. Chemical ionisation is more susceptible to source conditions and, in order to maximise the proton transfer process, a gas-tight source is essential. Any factor which reduces this, such as chipped interface jets, results in loss of sensitivity.

In addition to the confirmation of molecular weight, chemical ionisation may be used to indicate the

presence of a mixture, the spectrum usually containing a single intense ion from each component. This may be used to advantage in the analysis of thin-layer chromatography spots when the background spectrum, often prominent under electron impact conditions, is usually suppressed.

NEGATIVE IONS

The study of negative ions is more difficult because their abundance is usually 3 or 4 orders of magnitude less than that of positive ions. Also, they usually occur in the low mass range and are therefore of little structural significance. However, if the bombardment is carried out under chemical ionisation conditions using a reagent gas which, on electron impact, yields anions, e.g. methylene chloride, these combine with sample molecules to form negative cluster ions e.g. $(\text{M}+\text{Cl})^-$. Under these conditions the sensitivity of certain classes of compounds is several orders of magnitude greater than when using positive ion techniques. The types of compounds amenable to this type of analysis are those with high electron affinity, i.e. those often detected by electron capture in gas chromatography. It is, therefore, worthwhile considering the use of chemical derivatives such as pentafluorobenzoyl, heptafluorobutyryl, etc. to enhance the electron-capturing ability of the compounds under consideration.

Other soft ionisation techniques include field desorption, field ionisation, atmospheric pressure ionisation, and fast atom bombardment and each increases the range of molecules which may be studied by mass spectrometry. Vitamins of molecular weight around 1400 may now be studied and the molecular ion identified. These techniques are at present useful for confirmation of structure or molecular weight but because of the production of cluster ions such as $(\text{M} + \text{Na})^+$, $(\text{M} + 2\text{Na})^+$, 2M^+ , etc., they are not used in the investigation of unknowns.

Ion Separation

The collimated ion beam, having left the source, is separated into groups of ions of different mass to charge ratio (m/z) usually by employing a *magnetic sector* or a *quadrupole filter*. The ability of the mass spectrometer to separate these ions is termed the resolution, and mass spectrometers may be of low, medium, or high resolution.

Low resolution mass spectrometers essentially have resolution of the order of 1000 (i.e. they are able to

differentiate between m/z 1000 and 1001 or between m/z 100.0 and 100.1) and have a single mass separation stage. Medium and high or ultra-high resolution mass spectrometers have resolutions ranging from about 10 000 to about 150 000. They employ two separation/focussing stages and allow an m/z value to be determined to four decimal places and accurate atomic compositions to be obtained.

Ions, when subjected to an accelerating voltage, take up a circular path in a magnetic field. In a magnetic sector instrument, ions of different m/z may be brought to focus at a detector by variation of the magnetic field. Laminated magnets allow faster scan speeds than solid magnets because of their low hysteresis characteristics.

The quadrupole filter comprises four symmetrically arranged parallel rods. A field is set up in the space between the rods by the use of a radiofrequency field and a d.c. voltage which may be varied to allow ions of different m/z to reach the detector.

The main advantage of the quadrupole filter is its fast scan speed (scan speeds in the millisecond range are possible), since only a change in voltage is involved and problems associated with magnet hysteresis are not encountered. The ion source of a quadrupole mass spectrometer is maintained at very low voltages (typically tens of volts) while magnetic sector instruments require high voltages (typically 3 to 4 kV). Magnetic sector instruments are therefore much more susceptible to leaks, pressure fluctuations, and flashovers caused by dirty sources, etc. The mass range of a quadrupole filter is more limited than that of a magnetic sector instrument, commercial instruments being limited to ion masses below about 1200. However, this is not a practical problem since the vast majority of drugs have molecular weights below this limit. The intensity of an ion above about m/z 300 obtained using a quadrupole filter is usually less than that obtained from the same sample using a magnetic sector instrument, and this discrimination effect should be taken into account when spectra from quadrupole and magnetic sector instruments are compared. Further disadvantages of the quadrupole filter are that it is not capable of high resolution and that metastable peaks are not observed.

For most routine applications quadrupole instruments and single focussing magnetic sector instruments are of comparable performance. However, quadrupole instruments are much more compact.

Double Focussing Mass Spectrometers. Two factors that limit the resolution of a single focussing mass spectrometer to a maximum of about 5000 are the

angular divergence and the spread of the kinetic energies of the ions as they leave the source. To correct for these, an electrostatic analyser (ESA) is introduced, usually before the magnetic sector. The radius of curvature of an ion passing through an electrostatic analyser is determined by its kinetic energy. The beam of ions emerging from the source of a mass spectrometer is therefore brought to a focus at a series of points, each representing a common kinetic energy. These are then passed into the magnetic sector and the separate beams are refocussed at one point for each m/z ratio.

In this way, resolution of up to 150 000 and a mass-measurement accuracy of 0.3 ppm may be obtained. Thus the accurate molecular weight of a compound can be measured to ± 0.0002 mass units and an unambiguous assignment of the elemental composition of an ion may be made. For example, although dibutyl phthalate and triprolidine each have a nominal molecular weight of 278 their accurate molecular weights of 278.1556 and 278.1862 reflect their differing atomic compositions, $C_{16}H_{22}O_4$ and $C_{19}H_{22}N_2$, respectively.

The double focussing mass spectrometer also allows the use of a series of 'linked scanning' techniques. In conventional double focussing mass spectrometry, the electrostatic analyser voltage (E) is held constant while the magnetic field (B) is varied to generate the mass spectrum. If, however, B and E are linked in a specific way, various modes of ion decomposition may be studied. If the ratio B/E is kept constant, the daughter ions formed by decomposition of an individual ion may be studied. This may be used as an aid to structural determination since ions with the same atomic composition, but different structures, will fragment differently (the B/E linked scan of m/z 73 from $CH_3 \cdot CO \cdot O \cdot CH_2$ will be different from that obtained from $CH_2 \cdot CH_2 \cdot COOH$). This technique may also be used to obtain a fingerprint mass spectrum for identification purposes. By monitoring the molecular ion of a compound which may be present as a minor component of a mixture, only the fragmentation of this ion will be observed. Thus a characteristic mass spectrum will be obtained for that minor component and the background spectrum will be effectively removed.

Another application is the differentiation of closely related isomers. The conventional mass spectra of butobarbitone and secbutobarbitone are qualitatively identical (Figs 5A and 5B). The B/E linked scans of their $(M-29)^+$ ions (m/z 183) shown in Figs 5C and 5D

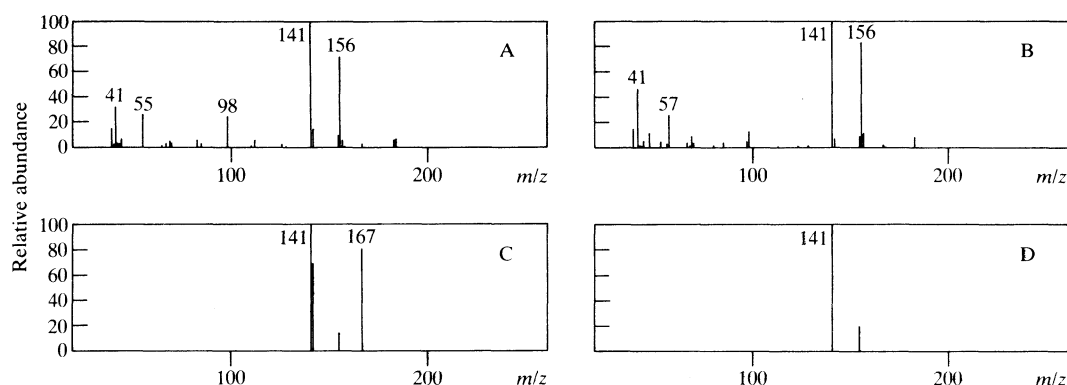

Fig. 5. Electron impact mass spectra of butobarbitone (A) and secbutobarbitone (B), and daughter-ion linked spectra of m/z 183 from butobarbitone (C) and secbutobarbitone (D).

are clearly different, thus allowing ready discrimination.

A similar technique applicable to reverse geometry mass spectrometers (magnetic sector before electrostatic analyser) is that of mass-analysed ion kinetic energy spectrometry (MIKES). In this technique the ion to be studied is 'isolated' by the magnet and induced to fragment by collision activation in a small chamber filled with a gas such as helium. The product ions are then detected by scanning the electrostatic analyser voltage.

If the electrostatic analyser voltage and magnetic field are scanned such that B^2/E is constant, all precursor ions of a selected daughter ion may be observed. The main use of this technique is in structure determinations to investigate the interrelationships of ions.

A third scanning mode, in which the ratio $B/E\sqrt{1-E}$ is kept constant, allows ions arising by a specific neutral loss to be observed. This permits ions containing a common functional group to be identified and related compounds in a mixture to be picked out. Similar results may be obtained by the use of a triple quadrupole arrangement in which the first quadrupole is used to isolate the ion of interest, the second as a collision cell to induce fragmentation, and the third to monitor the selected decomposition mode.

Ion Detection and Amplification

The beam of ions is directed through a set of resolving slits to a detector, usually an electron multiplier. The current generated is amplified, typically by a factor of 10^6 , so that it may be observed using an oscilloscope

and may be recorded using some device which allows a permanent record to be obtained.

Presentation of Results

The recording device must accept the data generated by the mass spectrometer at a range of scan speeds. It must also allow the ready comparison of the intensities of both major and minor ion peaks within a single scan. A chart recorder equipped with ultraviolet-sensitive paper and using a light beam instead of a pen is capable of producing simultaneous traces at different sensitivities and thus satisfies the requirements. However, a computer equipped with some sort of data storage device (data system) is now more common. Its advantage is that data may be stored permanently and manipulated in many sophisticated ways (background subtraction, library matching, etc.). Depending on the size of the storage device (magnetic tape, floppy or cartridge disk) either all scans or selected scans are stored. Simple systems allow data to be acquired, then processed only when data acquisition is complete. More complex systems include those in which one set of data may be acquired at the same time as a second set of data, either from the current run or from a previous run, is being manipulated (Foreground/Background). Other systems control several mass spectrometers at the same time as data processing is being carried out.

The data system detects ions occurring during a mass spectrometer scan and measures their intensities. The signal obtained is proportional to the number of ions of the particular m/z produced. Comparison with known masses obtained from a reference material,

allows the m/z of each peak to be calculated. This information is then stored together with other data such as the total ion current (TIC, the sum of all the individual ions), for a particular scan.

These data for successive scans are then stored for subsequent manipulation. The reconstructed total ion current trace, equivalent to that obtained from a flame ionisation detector in gas chromatography, shows the variation of total ion current with time and allows spectra of interest to be identified. A typical example is shown in Fig. 6A. The background may be subtracted to give clean spectra, and their identification may be attempted using libraries of standard spectra. If a composite spectrum is obtained from two unresolved peaks, complex subtraction routines may be used to obtain a pure spectrum of each of the components. These may be separately submitted for library searching. The spectra may then be plotted or obtained as a mass versus intensity listing.

Single ion chromatograms, i.e. the variation in intensity of a single ion with time, may be generated to identify particular components in a complex mixture or to identify particular structural fragments and thereby draw attention to peaks of special interest (Fig. 6B).

The data system therefore allows manipulations that are impracticable or impossible without the use of a computer and offers the great advantage that it is possible to re-examine the data at a later date.

Fig. 6. Reconstructed total ion current trace (A) and a single ion chromatogram from m/z 91 (B) for a typical GC-MS run.

PREPARATION OF SAMPLES FOR MASS SPECTROMETRIC ANALYSIS

The sample for examination may be the parent drug in a pharmaceutical preparation or illicit drug preparation, or may be the drug together with a metabolite in a complex biological sample. In the latter case, some degree of clean-up/separation is required prior to mass spectrometric analysis.

In drug preparations, sensitivity is not a particular problem as there is always sufficient of the active constituent present. Suitable extraction procedures should be carried out and each fraction should then be subjected to chromatographic analysis. The mass spectra, together with the appropriate retention parameters, may then be used for identification purposes. In many cases mass spectrometric analysis is undertaken as confirmation of an identification based on the physical characteristics such as size, colour, markings, etc., of the tablet or capsule.

Mass spectrometry may be used not only to identify the major components but also the trace impurities. This information may be used for quality control purposes, and may enable the route of manufacture of certain drugs to be determined.

The analysis of drugs in biological materials presents more of a problem since the amounts of material encountered are much smaller and they are in a much more complex sample. In most cases therefore, some type of clean-up procedure is carried out prior to chromatographic separation and mass spectrometric analysis. It is not usual to analyse this type of sample by use of the probe because of the excessive background spectrum that is obtained. However, this background may be reduced using the mass spectrometer in the chemical ionisation mode, and probe analysis can then be used as a screening technique. This can give significant information concerning compounds present, but will not usually allow discrimination between compounds with the same molecular weight. Chromatographic separation may be carried out to isolate the substance(s) of interest before analysis using thin-layer chromatography, paper chromatography, or preparative gas chromatography, or using 'on-line' chromatographic techniques (GC, HPLC) in which the separated substances pass directly into the mass spectrometer for analysis.

Thin-layer Chromatography and Paper Chromatography

The major problems encountered with these techniques are co-extraction of contaminants from the

chromatographic paper or plate, or from the solvents used for extraction.

The simplest method of transferring the material for analysis to the insertion probe of the mass spectrometer involves scraping off the relevant portion of the thin-layer plate or cutting the chromatographic paper and placing it in a micro test-tube. The drug is extracted by shaking with the minimum amount of a volatile solvent such as methanol, separating the supernatant liquid by centrifugation, transferring to the insertion probe, and then evaporating. Alternatively, the adsorbent from a thin-layer plate can be placed in a Pasteur pipette in which the constriction is packed with clean cotton wool and the material of interest eluted with about 50 μl of an appropriate solvent directly into the probe.

The problem of background spectra may be overcome by carrying out the above extraction procedure using a portion from an equivalent position on the plate or paper which has been run in the same solvent but with no sample. This spectrum may then be subtracted to give a clean spectrum of the sample. Thin-layer plates may be precleaned by running them in solvents before attempting to run a sample. The background spectra most often encountered, arising from solvent contaminants, is characterised by an intense ion of m/z 149 due to phthalate ester plasticisers.

Gas Chromatography

The interfaces which allow compatibility between the widely different pressure requirements of gas chromatography and mass spectrometry have been discussed previously. The main modification is the use of helium as the carrier gas in the chromatographic column. Since the carrier gas is ionised within the source of the mass spectrometer this will always contribute to the total ion current and will result in a high standing current. The use of a carrier gas having a high ionisation potential is therefore advocated to reduce this standing current. This may be further reduced by decreasing the energy of the bombarding electrons to a value which is below the relevant ionisation potential of the carrier gas but still allows efficient ionisation of the organic sample molecules. A value of 24 eV, compared with the more usual 70 eV, is normally used.

Problems caused by column bleed include elevated background in total ion current traces, contamination of the separator and/or ion source, and contamination of the spectra. These problems may be overcome

by using silicone polymer type stationary phases, which are thermally stable and inert. They are conditioned at their maximum operating temperature for several days, and then used at lower temperatures to reduce the level of bleed. Alternatively, a background spectrum may be obtained and then subtracted from the spectrum of interest in the same way as described for thin-layer and paper chromatography.

Capillary and packed columns impose different operating criteria upon the mass spectrometer. Packed columns usually give peaks with a width of about 20 to 30 seconds at half height, whereas capillary columns give peak widths of about 5 seconds. The scan speed of the mass spectrometer must be fast enough to ensure that spectra are not grossly distorted by the variation in concentration of the drug during the scan. If a computer is used, at least three scans must be obtained and averaged. This is not a problem with packed columns, when scan rates of 10 seconds/decade may be used to give high accuracy mass measurements. For capillary columns, a cycle time of less than 1 second is required and, in the past, this necessitated the use of quadrupole mass spectrometers with their inherently faster scan speeds. However, the development of laminated magnets has made it possible to scan at cycle times of about 0.5 seconds using a magnetic sector instrument. This is perfectly adequate to obtain high resolution data from the highest performance capillary columns. For overlapping peaks, examination of a series of consecutively obtained spectra enables the analyst to identify the ions associated with each component of the mixture. In each of the above cases which cause distortion of spectra, removal of background and deconvolution of overlapping peaks are most easily dealt with by use of a data system.

A restriction to the operation of GC-MS can be caused by solvent peaks. If the solvent injected onto a packed column flows via a separator into the ion source of the mass spectrometer, it results in an unacceptable increase in pressure which causes the built-in pressure protection devices to shut the mass spectrometer down. It also much reduces the lifetime of source components such as filaments and heaters. Therefore a valve is fitted at the end of the column, which allows effluent to be vented to a pump or to the atmosphere until the solvent has passed. The flow rates associated with the use of capillary columns are such that the pressure generated by the solvent is not as great as with a packed column. The total effluent may therefore be passed directly into

the source of the mass spectrometer, but in order to prolong the life of filaments etc. the mass spectrometer is usually turned off until the solvent elutes.

The temperature of the interface is of great importance. If it is too low the chromatographic performance is degraded or the material of interest simply condenses and is not observed, whilst if the temperature is too high, thermal decomposition or even pyrolysis may occur. The gas lines, if constructed of glass-lined tubing, should be uniformly heated, of the minimum possible length, and should not contain any sharp bends. These tend to crack after temperature cycling and lead to active sites in the tubing which again degrade performance and may result in small quantities of material being lost altogether. It should also be remembered that the mass spectrometer, in its qualitative mode, is equivalent to the flame ionisation detector in gas chromatography and, unless multiple ion detection or single ion monitoring is used, does not function as a selective detector.

Chemical derivatives may be used to improve the chromatographic characteristics of polar compounds, e.g. acids may be converted to their methyl esters and barbiturates to their methyl derivatives. This technique may also provide information concerning the number of active sites in a molecule by noting the increase in molecular weight on methylation. In many cases the mass spectrum of the derivative may be of more use for identification purposes.

High Pressure Liquid Chromatography

The use of HPLC-MS is far from routine. The fast scanning limitation is removed since peak widths are of the order of those associated with packed gas chromatography columns. Much greater spectrum background is encountered, however, to the extent that details below m/z 100 are completely obscured.

COMPOUND IDENTIFICATION

The identification of a compound from its mass spectrum may be achieved by matching the spectrum against libraries of spectra. However, if the compound is not already known, e.g. a drug intermediate or an unknown metabolite which is not in the library collections, the fragmentation pattern must be interpreted from first principles using as much other analytical information (UV, IR, NMR, etc.) as may be available.

Reference Collections

The most efficient way to use reference collections

of mass spectra is to build up a collection of spectra containing the compounds most likely to be encountered. Experience shows that a library of approximately 2000 spectra enables more than 80% of samples analysed to be identified.

With the advent of dedicated data systems it is now possible to store relatively large numbers of full spectra efficiently. However, for efficient searching it is necessary to abbreviate the spectra. For those without data systems it is also necessary to abbreviate the spectra in order to construct hard-copy indexes for manual searching.

Two equally efficient types of spectral abbreviation are in use, these being based on either the n (usually 8) most intense ions in the mass spectrum or the n in m range system in which the n largest ions in each m mass range are used (e.g. 1 in 7, 1 in 14, or 2 in 14). The main disadvantage of the n most intense ions system is that the ions could all be of low m/z and have little structural significance. This can result in library matches being obtained which are similar only in the ions due to the hydrocarbon moieties (m/z 57, 71, 85, etc.). A modification of this procedure involves the assignment of a 'significance factor' for the mass number in which ions of higher m/z are considered to be more significant than those of lower m/z . The intensity of each ion is then multiplied by this factor and the n most intense or most significant ions are used in the abbreviation. The advantage of the range system is that the significant high mass ions are always used. The n in m range system also allows ready coding of spectra using binary notation and leads to the identification of homologous series of ions.

Having decided on the format of a library of spectra, one must then consider how the data will be searched. Manually, the analyst extracts the relevant data from the spectrum of the 'unknown', orders them according to the format of the hard copy listing, and carries out the search. The analyst compares the similar spectra and uses his experience to judge which is the best match. It is possible for an experienced analyst to conclude that the mass spectrum is not a single component but a mixture since, although all ions in the library spectrum are present, there are also other significant ions present. These other ions are then used as the basis of a further search. Searches using data systems are carried out in a similar way but much more rapidly. Most computer programs list library matches in order of 'fit factor', a measure of the similarity between

the library spectrum and the 'unknown' spectrum. It is usually calculated using a formula involving the differences in intensities of matching ions in the two spectra. Two main types of search are used, the so-called forward and reverse searches.

In the forward search, all of the ions in both the library spectrum and the unknown spectrum are used in the calculation of the fit factor, while in the reverse search only the ions in the library spectrum are used in this calculation. Forward searches work well only for pure compounds, while the reverse search is admirably suited for dealing with the composite spectra from mixtures.

When small mass spectral collections do not identify an unknown, use is usually made of large, commercially available collections. The strength of these collections is their size, but it is also their weakness because manual searches take a considerable time and a large number of entries are irrelevant to some analysts. This weakness is of minor importance if the collection can be searched by a computer. Two major collections exist one of which, the EPA/NIH Mass Spectral Data Base, is available on a worldwide commercial time-share computer by the National Bureau of Standards, Washington, U.S.A. This data-base is accessible via a telephone and a suitable terminal. The collection contains around 34 000 spectra which may be searched in a variety of ways.

The simplest method is termed the 'peak' search in which a series of ions, within an intensity range, are input to the computer one by one. The file is then searched and the output consists of those spectra containing the required ion(s) with the correct intensity. Additional ions are then input and the first set of spectra is further reduced until eventually it contains only those entries which incorporate all of the ions required. When the subset has been reduced to a manageable number, a list of the relevant spectra may be produced, including information such as molecular weight, molecular formula, and reference number. A full listing of the peaks of these spectra is also available. The bar chart representation of this complete collection of spectra may be obtained in book form, arranged in order of molecular weight. Other computer searches which are available include molecular weight, peak and molecular weight, molecular formula, and peak and molecular formula. This collection is also available on commercially available data systems to allow interactive searching. The second collection available, both in book form

and on magnetic tape for computer searching, is The Eight Peak Index of Mass Spectra', published by the Mass Spectrometry Data Centre (MSDC) Nottingham. This differs from the previous collection in that it contains only the eight most intense peaks, with intensities; the 1983 edition contains data for over 60 000 spectra.

Interpretation of Mass Spectra

If it is not possible to identify a mass spectrum from library collections it is necessary to attempt the interpretation of the mass spectrum. However, before consideration of the mass spectrum all other available data should be collected together. For example, the method of extraction using acidic or basic conditions, should rule out a large number of possibilities. If possible, infra-red and ultraviolet spectra should be examined and chromatographic retention values should be determined. Armed with this information the mass spectrum can be examined. Firstly, the molecular ion (M^+) must be identified. This will probably be the ion of highest m/z in the spectrum, but this is not always the case. The molecular ion must be capable of yielding the other high mass ions observed in the spectrum by loss of convenient neutral species (losses of 4 to 14, 21 to 25, 33, 37, and 38 are highly unlikely). If possible, the molecular weight should be confirmed by use of a soft ionisation technique. If high resolution facilities are available, the accurate molecular composition may be determined from the molecular ion.

Even if only low resolution data are available, a great deal of information may be obtained. If the molecule has an odd mass it must contain an odd number of nitrogen atoms. If, however, it is of even mass it either contains no nitrogen or an even number of atoms of the element. This is a consequence of the even atomic weight and odd valency of nitrogen. The intensity of the molecular ion gives an indication of the structure. An intense M^+ indicates the presence of a stable ring structure. Chain branching substantially decreases the stability of M^+ . The presence of a multiplet in the M^+ region is often indicative of the presence of heteroatoms possessing characteristic isotopic patterns. The elements which are commonly identified in this way are silicon, sulphur, chlorine, and bromine, each of which gives characteristic contributions at ($M+2$) (^{28}Si : ^{29}Si : ^{30}Si - to give peaks in the ratio 100:5:3, ^{32}S : ^{34}S ratio 100:4, ^{35}Cl : ^{37}Cl ratio 3:1, and ^{79}Br : ^{81}Br ratio 1:1).

The high mass end of the spectrum is then examined for characteristic losses, and the low mass end for characteristic ions which may be rationalised in terms of the structure. The presence of metastable ions, not usually detected by data systems, gives information regarding the fragmentation pathways, this type of information being supplemented by that available from linked scanning experiments if a double focussing instrument is available. By examination of the interrelationships between the ions observed in a mass spectrum it is possible to work out a complete breakdown scheme and then by piecing together all the available information it is often possible to arrive at an unambiguous assignment of structure.

The information extracted and deduced in the steps above may be used in a different way in an attempt to identify an unknown compound. This utilises a file of known chemical structures stored in a computer-compatible form known as the Wiswesser Line Notation (WLN). This notation retains sub-structural information and forms the basis of a search system (R. E. Ardrey and C. Brown, *J. forens. Sci. Soc.*, 1977, 77, 63-71). The types of information available from the mass spectrum, i.e. molecular weight, accurate atomic composition, structural groups, presence of heteroatoms with characteristic isotopic patterns, etc., are supplemented with the information from other analytical techniques. The ultraviolet spectrum may suggest, for example, a barbiturate, and the infra-red spectrum may, for example, exclude the presence of certain chemical groupings. When these data are entered into the search program via an interactive input, the output consists of a list of all structures which fulfil the required analytical criteria. The analyst must then consider each structure in the light of the evidence at his disposal. Certain aspects of the analytical data may not seem significant on first consideration but, when taken in the light of a possible structure, may assume greater importance. Having reduced the list of possible structures to manageable numbers, hopefully only one or two, it is best to obtain a genuine sample of the material and compare analytical data.

QUANTIFICATION

The technique known variously as multiple ion detection (MID), selected ion recording (SIR), and selected ion monitoring (SIM) employs the mass spectrometer to monitor only a few significant ions. In this way both the sensitivity and selectivity are increased markedly, the former by a factor ap-

proaching 100 due to the increased amount of time spent monitoring each particular ion. For the successful quantitative estimation of a compound its mass spectrum should contain at least two reasonably intense ions at the high mass end of the spectrum. By using two ions of known relative abundance from the parent compound, contributions at these masses from extraneous material present can be ruled out and thereby increase the precision of the determination.

It is also advantageous to have access to a substance which may be used as an internal standard. This should be chemically similar to the material under investigation, should possess two ions capable of being monitored, but should not have significant ion contributions at the masses previously chosen for monitoring. Ideally, a deuterated derivative or homologue of the material to be determined is used. The internal standard should be added prior to any clean-up/extraction procedure so that any losses will apply equally to both the internal standard and the drug under investigation. Using a calibration graph of relative peak heights/areas of particular ions from solutions containing a fixed amount of internal standard plotted against different amounts of the drug of interest, a direct determination of the amount in an unknown solution can be made. It is possible to measure picogram concentrations of materials from biological extracts, although the detection limit is set not by the sensitivity of the mass spectrometer but by the interference generated by co-extracted materials, etc. If a double focussing instrument is available, the selectivity may be increased further by monitoring the accurate mass corresponding to a particular atomic composition rather than the nominal integer mass.

Double focussing instrumentation also allows the monitoring of metastable transitions. This technique increases the sensitivity and specificity because metastable ions are observed at non-integer m/z values where there are no other ions.

MASS SPECTRAL DATA

Many of the monographs in Part 2 contain mass spectral data in the form of the eight most intense ions, in descending order of intensity. These values have also been used to compile an 8-peak index in Part 3 for rapid searching for an unknown.

The complete mass spectra for about 1000 drugs, metabolites, and other compounds of forensic and pharmaceutical interest are reproduced in *Pharmaceutical Mass Spectra*, London, Pharmaceutical Press, 1985. This collection also contains three 8-peak indexes in which

substances appear alphabetically by name, in numerical order of base peak, and in order of molecular weight.

Nuclear Magnetic Resonance Spectroscopy

G. P. Carr

Nuclear magnetic resonance Spectroscopy (NMR) is based on the fact that when nuclei of NMR-active species are placed in a magnetic field they distribute themselves into a number of quantised orientations with respect to this field. Each orientation corresponds to an energy level and if the nucleus is then subjected to an oscillating radiofrequency field of the correct frequency, energy is absorbed and transitions between these energy levels are induced. NMR Spectroscopy involves detecting the absorption of energy with a radio-frequency receiver and observing the frequencies at which such transitions occur.

The number of orientations available to a nucleus varies depending on its type, in accordance with the following principle. The nuclei of all atoms carry a positive charge and, in the case of some isotopes, possess spin. These nuclei therefore have an angular momentum defined by $I(I+1)h/2\pi$, where I is the spin quantum number and h is Planck's constant. The value of I varies for different nuclei and may be 0, 1/2, 1, 3/2, ... Nuclei for which $I=0$ are not NMR-active and some important atoms are included in this category, e.g. ^{12}C and ^{16}O , all of which have mass numbers which are divisible by four. Examples of NMR-active nuclei are ^1H , ^{13}C and ^{19}F ($I=1/2$), ^{14}N and ^2H ($I=1$), and ^{11}B ($I=3/2$).

Detailed descriptions of the theory and instrumentation of nuclear magnetic resonance Spectroscopy can be found elsewhere (see Bibliography). In this chapter the important features of the NMR spectrum and their use in the interpretation of spectra are described, together with details of certain special procedures which assist interpretation.

THE NMR SPECTRUM

Chemical Shift

Nuclei are brought to resonance as a result of the absorption of energy from a radiofrequency oscillator of the correct frequency. The value of this

frequency is dependent on the intensity of the magnetic field being experienced by the nucleus, which in turn is dependent on various factors. Firstly, there is the operating field strength of the spectrometer. Various instruments are available in this respect, e.g. with an operating field strength of 1.41 T (14 100 gauss) in which the proton comes to resonance at 60 MHz, or of 2.35 T (23 500 gauss) for which the resonance frequency for the proton is 100 MHz. Instruments containing magnets with field strengths up to about 9.4 T (94 000 gauss) are available but spectrometers operating at frequencies (ν) of about 60 MHz to 220 MHz for protons are probably the most widely used.

The second feature that influences this magnetic field is the environment of the nucleus within the molecule. The distribution of electrons around the nucleus, or around neighbouring atoms within the molecule, serves to screen it from the magnetic field so that the field actually experienced by each individual nucleus in the molecule may be different. Thus the frequency at which they come to resonance is also different. This effect is known as *shielding*. Nuclei surrounded by a relatively high level of electron density are referred to as *shielded* and those with a relatively low level of electron density as *deshielded*. As a result of shielding, nuclei come to resonance at frequencies which are characteristic of the functional groups associated with them and the different positions of these resonance lines are called chemical shifts.

This is demonstrated in Fig. 1 which illustrates the proton spectrum of 1,4-bis(2-oxopropoxy)-benzene. Spectra are conventionally scanned from low field to high field with the low field end on the left. The aromatic protons are the least shielded followed by the methylene protons and then the methyl protons which are the most shielded.

It is not necessary to know the absolute value of resonance frequencies. It is sufficient and far more convenient to determine chemical shifts relative to

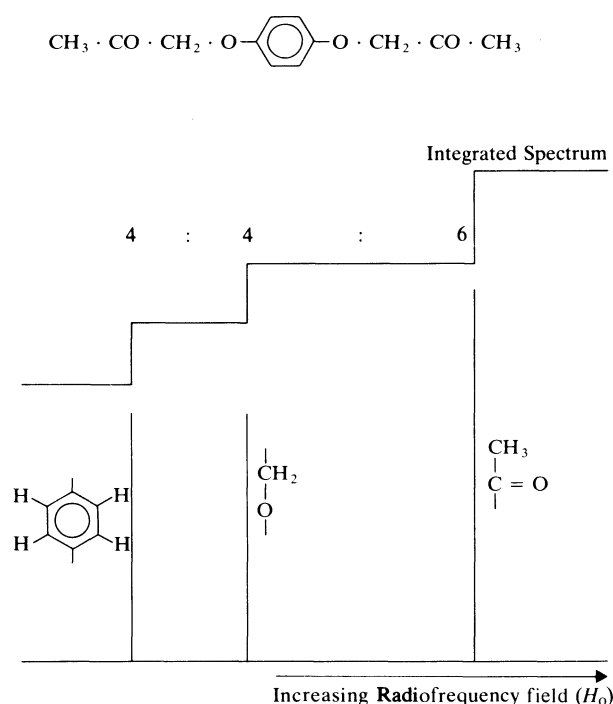

Fig. 1. Diagram of the proton spectrum of 1,4-bis(2-oxopropoxy)benzene.

a standard reference substance. The reference substance used for samples in organic solvents, in both proton magnetic resonance (PMR) and ^{13}C spectroscopy, is tetramethylsilane (TMS). Since silicon is less electronegative than carbon, the four methyl groups are strongly shielded by the high electron density surrounding them. This leads to readily identifiable proton and ^{13}C signals which are at higher fields than the resonances of most organic molecules commonly encountered. Tetramethylsilane is not soluble in water and the usual standard for deuterium oxide (D_2O) solutions is sodium 3-(trimethylsilyl)propanesulphonate (TSS). Since the operating frequency of a spectrometer is dependent on the field strength of its magnet, the frequency at which a particular sample comes to resonance will be different in instruments containing magnets of different field strengths. Chemical shift data are therefore expressed in a form which is independent of the operating frequency of the instrument, i.e. δ parts per million, where

$$\delta = \frac{\text{Difference in resonance frequency between sample and TMS}}{\text{Operating frequency of the spectrometer}} \times 10^6 \text{ ppm}$$

The ratio is multiplied by 10^6 so that the data are in a more convenient form. Thus if tetramethylsilane is arbitrarily set at δ 0.00, the majority of proton resonances occur in the range 0 to 10 ppm. An alternative scale is the τ scale which is defined as $10 - \delta$ ppm so that tetramethylsilane is set at τ 10.00 ppm. This scale is only really of value for proton spectroscopy and all further data in this chapter will be expressed on the δ scale.

Although their resonance frequencies may be different, the transitions undergone by protons in different groups represent the same energy change. As a result, the ratio of the integrated intensities of signals is equal to the ratio of the number of protons in each group.

In Fig. 1 there are four aromatic protons, four methylene protons, and six methyl protons so that the ratio of the integrated intensities of these three signals is 4:4:6. This is very useful since it provides information on the relative numbers of protons responsible for resonance signals thereby assisting in the interpretation of spectra. This proportionality does not occur so readily in ^{13}C spectroscopy. Since chemical shifts are dependent on the nature of the functional groups associated with the nucleus, tables have been compiled to correlate this data (see Bibliography).

Spin-spin Coupling

On a high-resolution spectrometer, the resonance lines corresponding to groups of equivalent nuclei frequently exhibit fine structure. Thus, under certain circumstances, resonance signals may be split into doublets, triplets, quartets, etc. This splitting is known as spin-spin coupling.

In Fig. 2 protons H_1 and H_2 resonate at quite different chemical shifts and are both split into doublets with the spacings between the two elements of both doublets being equal. This spacing is called the *coupling constant*. Coupling constants are measured in Hz, their values are characteristic of certain

Fig. 2. Diagram of the proton spectrum of $\text{CHR}_1\text{R}_2\text{—CHR}_3\text{R}_4$ showing spin-spin coupling.

molecular features and are independent of the field strength of the spectrometer. They are conventionally referred to as values of J with appropriate subscripts to define the particular couplings of interest. So in Fig. 2, having assigned one of the protons as H_1 and the other as H_2 , the coupling constant may be written as

$$J_{1,2} = x\text{Hz}$$

The multiplicity of a coupling system depends essentially on two factors—the number of equivalent nuclei with which the nucleus of interest is coupling (n), and their spin quantum numbers (I). These two factors may be combined by the expression

$$\text{number of observed lines} = 2nl + 1$$

Thus in Fig. 2 for each proton, $n=1$ and $I=1/2$ and there are, therefore, two lines. In the example $\text{CH}_3\text{—CH}_2\text{—X}$, where X is a functional group such that the chemical shifts of the methyl and methylene protons are very different, the multiplicity of observed lines is greater. For the methyl group, $n=2$ and for the methylene group $n=3$, so the methyl group is split into a triplet and the methylene group into a quartet (Fig. 3). Once again the spacings between the elements of the multiplets (coupling constants) are the same in both groups. These splittings are explained by considering the factors that cause nuclei in different environments to resonate at different chemical shifts. One of these factors is that the magnetic field experienced by the nucleus is influenced by adjacent NMR-active nuclei. However, these adjacent nuclei can exist in

Fig. 3. Diagram of the proton spectrum of $\text{CH}_3\text{—CH}_2\text{—X}$ showing spin-spin coupling.

different spin states, each of which has a slightly different modifying effect on the applied field. This is expressed diagrammatically in Fig. 4 for the ethyl group, the coupling system of which is shown in Fig. 3.

From this it can be seen that there are four possible types of spin arrangement for the protons of the methyl group and that the relative probabilities of the four spin arrangements are in the ratio 1:3:3:1. Since each of these spin states results in a slightly different chemical shift for the methylene signal, this signal is then dispersed into four lines, the integrated intensities of which are also in the ratio 1:3:3:1.

From Fig. 4, a similar explanation may be derived for the splitting of the signal due to the methyl group into three lines, the integrated intensities of which are theoretically in the ratio 1:2:1. Provided the coupling constant remains the same for all nuclei concerned, the ideal relative intensities of the elements of a multiplet are in accordance with the coefficients of x in the binomial expansion $(1+x)^n$ where n is the number of nuclei with which the nucleus is coupling. More conveniently the multiplet may be considered as lying symmetrically about the centre of the resonance band with the relative intensities of the lines in accordance with a Pascal triangle, i.e., $n=0$, no split; $n=1$, lines split 1-1; $n=2$, lines split 1-2-1; $n=3$, lines split 1-3-3-1, etc. The chemical shift of the resonance concerned is theoretically the centre of the multiplet.

Spin-spin coupling does not usually occur between nuclei which are separated by more than three bonds,

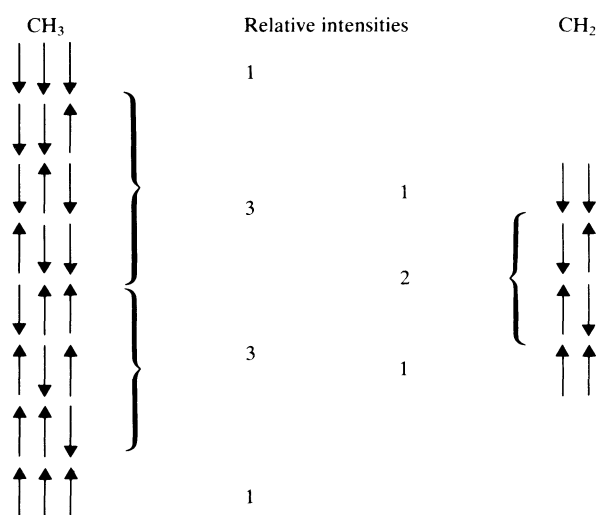

Fig. 4. Diagram of the spin states which give rise to spin-spin coupling between the protons of an ethyl group.

except in conjugated systems where couplings may be observed between nuclei separated by up to five bonds. The magnitude of the coupling constants in such 'long-range' systems is, however, very low. Thus, whereas coupling constants between protons on neighbouring carbon atoms of a freely-rotating hydrocarbon chain have values of about 6 to 7 Hz, the coupling constants between protons *para* to each other in a phenyl ring have values of about 0 to 1 Hz. Coupling constants between protons may be as high as 18 Hz for *gem*-protons or *trans*-olefinic protons. Much higher coupling constants, however, occur with other nuclei; for example values of up to about 80 Hz may be observed between protons and ^{19}F and up to about 200 Hz between protons and ^{13}C . Coupling systems in which the number and relative intensities of observed lines are in accordance with that predicted from the principles outlined above are rarely obtained in practice. To obtain such a spectrum, it would be necessary for the difference in chemical shift of the two resonances to be at least ten times their coupling constant, i.e. for two sets of coupled, equivalent nuclei for which $J_{1,2} = 5$ Hz they should come to resonance with chemical shifts at least 50 Hz from each other. When this condition is satisfied the spectrum is described as first order. As the chemical shift difference becomes smaller, spectra gradually diverge from first order. This first becomes apparent when the integrated intensities of the lines of coupling systems show deviations from the predicted intensities. This is demonstrated for the methyl and methylene coupling system in an ethyl group in Fig. 5.

The inner lines of the coupling system increase in intensity at the expense of the outer lines. Thus, although the overall integrated intensities of the methyl and methylene groups retain their 3:2 ratio, the elements of the triplet and quartet do not retain their predicted values. This phenomenon is referred to as *roofing* and often assists in the interpretation of spectra containing several coupling systems. Since the elements of a coupling system tend to 'roof' towards each other it provides a means of identifying which groups of resonances are associated with each other. This loss of first order characteristics can therefore be of great advantage and in practice it is very rare to obtain spectra which do not show some evidence of roofing.

Fig. 5. Diagram of the spin-spin coupling between the protons of an ethyl group showing loss of first-order character as the ratio $\Delta\nu/J$ decreases.

When the chemical shifts of nuclei are very close together, the number of lines observed often becomes greater than expected which can cause considerable difficulties in interpretation. An advantage of using spectrometers with higher operating frequencies is that they are more likely to produce spectra of greater first order character. Finally, when the chemical shifts of the nuclei concerned are almost identical, the coupling system completely collapses, degenerating to a single line. Alternatively when a coupling system consists of more than two interacting groups, the overall multiplicity obtained is the sum of those expected from each coupling.

In order to define different types of spin system, the participating nuclei are designated letters of the alphabet such that when their chemical shift difference $\Delta\nu$ is much greater than their coupling constant J the letters are widely separated and

when Δn is similar to J , the letters are closer together. When more than one nucleus of the same magnetic type is responsible for the signal, the letter is given a subscript to indicate the number of nuclei. Thus the two *ortho* protons of a 1,2,3,4-tetrasubstituted benzene may give rise to an AB system and the methyl and methylene protons of an ethyl group may give rise to an A_2X_3 system. This method provides a classification of coupling systems and assists in the recognition of certain molecular features. Thus a vinyl group and a 1,2,4-trisubstituted phenyl ring may both be described as an ABX system and would be expected to give rise to twelve lines as three pairs of doublets.

PREPARATION OF SPECTRA

NMR spectra are normally prepared using solutions. For liquid samples the spectra may be recorded 'neat' although better spectra are usually obtained using a solvent since viscous liquids produce resonance signals with broad lines which are therefore less well resolved. Solvents must be chemically inert and exhibit minimal resonance signals (both in number and amplitude). Thus, for proton spectroscopy the ideal solvent might be carbon tetrachloride, its limitation being that many samples are insufficiently soluble in it. Many common solvents contain protons but they are available as their deuterated analogues, e.g. D_2O , $CDCl_3$, $(CD_3)_2CO$, etc.

One of the main drawbacks of NMR is its lack of sensitivity. For a continuous wave proton spectrum, about 0.25 to 0.5 ml of solution containing about 20 mg of sample is preferred, but this may be reduced to about 5 mg if the instrument is operated at its maximum sensitivity. Microcells are available which allow spectra to be acquired with only about 25 μ l of solution and hence about 1 mg of sample.

Another technique for increasing sensitivity is by use of a Computer of Average Transients (CAT). This may be used to collect several scans of the spectrum of a sample and improves sensitivity because sample signals are accumulated whereas random noise signals are averaged. This, however, only leads to an increase of sensitivity equal to the square root of the number of scans. Since a single scan takes about five minutes it would therefore require about eight hours to gain a ten times increase in sensitivity. By using a CAT together with a microcell it is feasible to obtain a spectrum with 100 μ g of sample.

The spectral accumulation approach is also used in Fourier Transform Spectrometers. In this case spectral data are collected far more rapidly and spectra may be obtained in a reasonable period of time from about 20 μ g of sample. However, these instruments are much more expensive than continuous wave spectrometers although they may also be used to prepare ^{13}C spectra.

Sample solutions should be free from solid particles for maximum resolution and placed in glass sample tubes. For proton spectra, tubes of about 5 mm outside diameter are used, although for ^{13}C spectroscopy, tubes of wider bore are generally used to increase sensitivity. The tube is inserted between the poles of the magnet of the spectrometer and spun at about 30 Hz in order to average out any inhomogeneities of the applied field in different parts of the tube. Having selected suitable settings for the amplitude of the irradiating frequency and amplification of detected signals, the spectrum is recorded over a suitable sweep width using a scan speed of about 2 Hz per second.

Although NMR is relatively insensitive, it is also non-destructive and so valuable samples may be subsequently recovered for further experimental work.

INTERPRETATION OF SPECTRA

The following procedure provides a convenient method for the interpretation of proton spectra and it is useful to tabulate these data.

1. Determine the chemical shifts for each resonance.
2. Determine the relative numbers of protons responsible for each resonance from their integrated intensities.
3. Determine the multiplicities and coupling constants for each resonance.

From chemical shift tables it should be possible to identify possible functional groups that may be associated with the observed resonances. At this point, other analytical information becomes very useful e.g. the elements which are present and infrared or ultraviolet data, especially for functional groups. Using integrated intensities, multiplicities, and coupling constants, considerable information is provided on how the groups responsible for resonances fit in the molecule, relative to each other. The use of this procedure is demonstrated for a simple example, benzocaine, the proton spectrum of which is shown in Fig. 6 and in Table 1.

Fig. 6. PMR spectrum of benzocaine (10% solution in deuteriochloroform).

Table 1. Data from proton magnetic resonance spectrum of benzocaine

Chemical shift δ ppm	Relative number of protons	Multiplicity	Coupling constants Hz
1.35	3	Triplet	7
4.15	Total of 4 for δ 4.15 and δ 4.36 signals	Very broad	—
4.36		Quartet	7
6.68	2	Doublet with some fine coupling	9
7.90	2	Doublet with some fine coupling	9

A signal also appears at about δ 7.30 ppm and this can be identified as an impurity since its integrated intensity corresponds to only about 0.2 protons. It is due to the proton of chloroform which is present as a trace impurity in the solvent, deuteriochloroform (CDCl_3).

The δ 1.35 ppm signal is assignable to the three methyl protons. In a straight-chain hydrocarbon, methyl protons would be expected to resonate at about δ 0.9 ppm but the oxygen atom of the ester group β to the $-\text{CH}_3$ causes slight deshielding which would be expected to add about 0.4 ppm to the chemical shift. Furthermore, the integrated intensity of the signal corresponds to three protons and its multiplicity, a triplet with a coupling constant of 7 Hz, is consistent with the $-\text{CH}_3$ of an ethyl group. The δ 4.36 ppm signal is assignable to the two methylene protons. The methylene protons of a straight-chain hydrocarbon are expected to reso-

nate at about δ 1.25 ppm. However, oxygen has a very strong deshielding effect and a methylene group attached to the oxygen atom of an aromatic ester group is expected to show a signal at about δ 4.3 ppm. When comparing calculated with observed chemical shifts, a fit to within 0.1 ppm is generally expected, but it may sometimes degenerate to ± 0.2 ppm when there are several substituents influencing the final result. Another cause of error occurs when the resonance is split into a multiplet. Here the true chemical shift is rarely at the centre of the multiplet as account must be taken of the 'roofing' effect so that the chemical shift is the 'centre of gravity' of the multiplet. The integrated intensity of the δ 4.36 ppm signal corresponds to two protons and the multiplicity, a quartet with a coupling constant of 7 Hz, is consistent with the $-\text{CH}_2-$ of an ethyl group. This quartet and triplet pattern is typical of an A_2X_3 spin system in which the two methylene protons are the A_2 protons and the X_3 represents the three methyl protons.

The broad signal centred at about δ 4.15 ppm, due to the two amino protons, is of interest. ^{14}N is an NMR-active nucleus for which $I=1$. Using the formula of $(2nI+1)$, this signal would be expected to be a triplet. However, like many other nuclei for which I is greater than $1/2$, ^{14}N possesses a quadrupole moment. This is capable of providing an efficient relaxation mechanism for this nucleus and the broad resonance observed represents the resulting collapse of the $^{14}\text{N}-^1\text{H}$ coupling. In many cases, this collapse is sufficient to provide a fairly sharp signal. The position of amino signals is very variable, probably being dependent on the basicity of the nitrogen, i.e. the greater the basicity, the more available are the lone pair of electrons for shielding the attached protons, so that the resonance is observed at higher fields. Typically, amino resonances are observed in the range δ 1 ppm to δ 4 ppm. In this case, therefore, the signal, at δ 4.15 ppm is at a particularly low field. This is probably due to the electron-withdrawing effect of the *para* ester function on the lone pair of electrons on the nitrogen thus deshielding its attached protons.

The resonances at δ 6.68 ppm and δ 7.90 ppm are assignable to aromatic protons. The positions of aromatic protons are very strongly influenced by substituents. As a general rule, activating substituents lead to shielding, especially of the *ortho* and *para* protons, and therefore to chemical shifts at higher fields than δ 7.27 ppm (the chemical shift of

the protons of benzene) whereas, deactivating substituents lead to deshielding and chemical shifts at lower fields than $\delta 7.27$ ppm. Expected chemical shifts are calculated from the sum of the shielding or deshielding effects of all substituents. Thus, in this case, for each resonance we must take account of an *ortho* and *meta* substituent. For the protons on C_2 and C_6 there is an *ortho* ester group for which 0.75 ppm should be added and a *meta* amino group for which 0.25 ppm should be subtracted, leading to an expected value of $\delta 7.77$ ppm. For the protons on C_3 and C_5 there is an *ortho* amino group for which 0.75 ppm should be subtracted and a *meta* ester group for which 0.15 ppm should be added, leading to an expected value of $\delta 56.67$ ppm.

These calculations are generally expected to provide agreement with observed values to within about 0.2 ppm but variations may occur due to complex substituents and interactions between substituents. Since the protons on the aromatic ring resonate at different chemical shifts, the degeneracy of the signal is removed and coupling systems are set up which can exhibit long range coupling. For phenyl systems, the coupling constants are 7 to 10 Hz for *ortho* protons, 2 to 3 Hz for *meta* protons, and 0 to 1 Hz for *para* protons. In this case the coupling constant is 8.5 Hz and therefore characteristic of an *ortho* coupling as expected but showing some fine splitting. Thus although the pairs of protons on C_2 and C_6 and those on C_3 and C_5 are chemically equivalent it is incorrect to refer to this as an A_2B_2 system as this would show simply a pair of doublets with no fine coupling. It is more correct to consider this system as $AA'BB'$ to account for the weak *para* couplings. It is often found that spectra cannot be readily interpreted due to complications that may arise because of, for instance, overlap of the coupling system of two or more resonances or multiplets caused by several couplings. Under these circumstances it is useful to simplify the spectrum in order to assist with interpretation, and there are various means available for this including spin decoupling techniques and the use of lanthanide shift reagents.

Spin Decoupling

An AX spin system is expected to show a pair of doublets (assuming that both A and X were nuclei for which $I=1/2$). If a second radiofrequency ν_2 is then applied at the resonance frequency of nucleus A, the signal corresponding to X will collapse to a singlet. This process is called *spin decoupling* and in

this example the X resonance is said to be *decouple*. In order to achieve complete collapse of the X resonance, ν_2 must be much more powerful than ν_1 (the normal applied frequency). If ν_2 is relatively weaker, partial decoupling may be achieved which leads to incompletely collapsed systems. This can also provide useful information and is called *spin tickling*.

Since ν_2 is a powerful radiofrequency field, it causes *saturation* of nucleus A, i.e. the change of spin state of nucleus A is very rapid. Under these conditions, nucleus X does not exhibit signals corresponding to interaction with the two spin states of A but only a single time-averaged line is observed and this resonance signal therefore represents the true chemical shift of nucleus X.

This effect is demonstrated with propyl hydroxybenzoate (Fig. 7A) in which the α -methylene group resonates as a triplet at $\delta 4.32$ ppm, the central methylene group as a sextet centred at $\delta 1.84$ ppm, and the methyl group as a triplet at $\delta 1.00$ ppm. Irradiation of the $\delta 1.84$ ppm signal collapses both triplets to singlets (Fig. 7B). Irradiation of the $\delta 4.32$ ppm triplet collapses the $\delta 1.84$ ppm signal to a quartet (Fig. 7C) and this signal collapses to a triplet when the $\delta 1.00$ ppm resonance is irradiated (Fig. 7D). Irradiation of the $\delta 4.32$ ppm signal has no effect on the $\delta 1.00$ ppm triplet and vice versa (Fig. 7C and 7D, respectively).

Lanthanide Shift Reagents

If a paramagnetic metal complex is added to a sample the chemical shifts may be altered very significantly; certain lanthanide complexes can produce good shifted spectra without causing the unacceptable line broadening which is often observed when first row transition elements are used. Probably the lanthanide most used for this purpose is europium, usually in the form of a β -diketone complex such as tris(1,1,1,2,2,3,3-heptafluoro-7,7-dimethyloctan-4,5-dionato)europium (known as Eu(FOD)₃).

Lanthanide shift reagents are weak Lewis acids and, on addition to a substrate, are coordinated to basic sites. The ability of basic sites to coordinate decreases in the following order:

amines > hydroxyls > ketones > aldehydes > ethers
> esters > nitriles

The shift reagent is added in incremental portions and the spectrum scanned after each addition. Coordination of the metal to basic sites is a reversible process and time-averaged chemical shifts are

Fig. 7. Decoupled spectrum of propyl hydroxybenzoate (10% solution in deuteriochloroform). A, spectrum showing complete couplings; B, decoupling frequency set at $\delta 1.84$ ppm; C, decoupling frequency set at $\delta 4.32$ ppm; D, decoupling frequency set at $\delta 1.00$ ppm.

observed, the affected nuclei being shifted further on successive additions of reagent. Since nuclei which are closest, via bonds, to the coordination sites (for contact shifts) or closest, through space, to

the metal ion (for pseudocontact shifts) are most affected, valuable information on structure may be established from the extent that resonance signals are shifted.

The effect of a shift reagent is demonstrated in Fig. 8 using 2-aminoheptane. Spectrum A is the proton spectrum of 2-aminoheptane before adding the shift reagent. It shows a broadened multiplet centred at about $\delta 2.9$ ppm. This may be assigned to the methine proton on C_2 and should show as a sextet. It is probably broadened because of the proximity of the nitrogen atom. A clear methyl triplet is seen centred at $\delta 1.0$ ppm which may be assigned to the protons on C_7 and the remaining 13 protons are in the broad resonance at $\delta 1.1$ to $\delta 1.5$ ppm.

After addition of 0.35 mole equivalents of $\text{Eu}(\text{FOD})_3$, spectrum B is obtained. The C_2 methine proton has now shifted to $\delta 7.8$ ppm but the outside lines of the sextet structure are very poorly resolved. The C_1 methyl doublet shows at $\delta 5.3$ ppm but now

Fig. 8. Lanthanide-shifted spectrum of 2-aminoheptane (10% solution in deuteriochloroform). A, before adding $\text{Eu}(\text{FOD})_3$; B, after adding $\text{Eu}(\text{FOD})_3$.

another sextet has become resolved centred at δ 4.35 ppm. The only other sextet normally expected for 2-aminoheptane would be due to the C_6 methylene protons but this resonance would not be expected to be so strongly influenced by the shift reagent. A more likely explanation is that this signal is due to the C_3 methylene group and that the presence of the large europium-containing molecule is preventing free rotation of this group so that the two methylene protons are not equivalent. Each proton therefore produces a separate signal, one at around δ 4.3 ppm and the other at around δ 4.5 ppm. These then couple as usual with the neighbouring methine and methylene protons on C_2 and C_4 and also with each other and this would be expected to provide a pair of overlapping quintets. The quintet centred at δ 3.3 ppm is almost certainly due to the C_4 methylene protons. The elements of this quintet appear rather broad and this could be due to slightly different coupling constants for the two couplings with the non-equivalent protons on C_3 . The C_5 and C_6 methylene protons are not resolved from each other.

^{13}C SPECTROSCOPY

The most abundant isotope of carbon, ^{12}C , is a nucleus for which $I=0$ and it is therefore NMR-inactive. This is probably very desirable since if it were not the case, proton spectra would include C—H coupling, leading to very complicated coupling systems and making interpretation extremely difficult. However, ^{13}C is NMR-active ($I=1/2$).

Carbon spectroscopy has the problem of low sensitivity because the natural abundance of ^{13}C is only about 1.1%, the energy difference between the two spin states is very low, and relaxation times are long. However, the sensitivity problems have been overcome to a large extent by the development of pulsed spectrometers and by the introduction of stable wide-bore magnets which allow the use of wider sample tubes and thereby increase the amount of material being sampled between the poles of the magnet.

In a pulsed NMR experiment, the sample is irradiated with a strong, wide band radiofrequency pulse. As a result of this, all the nuclei precess with the Larmor frequencies characteristic of their environments generating a transverse magnetic field which decays exponentially. This is called *free induction decay* and contains all the information of a conventional frequency spectrum except that it requires conversion by Fourier transformation using a computer into

a form which may be interpreted visually by the spectroscopist.

Nuclear Overhauser Enhancement

Since the natural abundance of ^{13}C is very low, the probability of a molecule containing adjacent ^{13}C atoms is also very low and so in natural abundance ^{13}C spectroscopy experiments, ^{13}C — ^{13}C coupling is not observed. However, ^{13}C — ^1H coupling is observed and the coupling constants may be quite high, e.g. 120 to 200 Hz, causing considerable complications to the spectrum. This may be overcome by decoupling the complete proton spectrum, thereby producing a *noise-decoupled spectrum*. This has the added advantage that the sensitivity of the carbon lines is improved because multiplets have become concentrated into singlets. In addition, under proton decoupled conditions, it is found that the spin populations of the ^{13}C energy levels become redistributed such that the population difference between the ground and excited states increases. This is Nuclear Overhauser Enhancement (NOE) and it results in greater sensitivity, generally producing about a threefold enhancement of signals. Since quaternary carbon atoms have no attached protons, it might be expected that this enhancement would be reduced in their resonance signals, and in small molecules this is found to be the case. In larger molecules, however, a full enhancement is often observed, but this difference in enhancement is one of the reasons for limitations in quantitative ^{13}C spectroscopy.

Relaxation

After each pulse, nuclei should be allowed to relax before subjecting them to a subsequent pulse. However, there are considerable variations for relaxation times even for ^{13}C atoms within the same molecule, ranging from about 10^{-2} to 10^3 seconds. In practice, a compromise is used in which only partial relaxation is allowed between pulses; since complete relaxation is not allowed, ^{13}C nuclei in different environments within the same molecule are likely to have different integrated intensities. This is probably the main limitation to quantitative ^{13}C spectroscopy.

Off-resonance Decoupling

Although proton coupling can cause considerable complications to the spectrum, it is often very helpful to have some information on ^{13}C — ^1H couplings to assist interpretation. If the multiplicity of the coupling

system is known, it is possible to identify the primary, secondary, tertiary, and quaternary ^{13}C atoms of the molecule. This is achieved by using off-resonance decoupling. Off-resonance decoupled spectra are produced by irradiating the sample at a frequency which is just outside the proton spectral range while acquiring the ^{13}C spectrum. Under these conditions, partial proton decoupling results so that multiplicities may be observed, but the spacings between the lines of multiplets are reduced. Protons which resonate closer to the decoupling frequency show greater reduction of these spacings, which also provides useful structural information.

Fig. 9A shows a fully noise-decoupled spectrum of pilocarpine nitrate. One feature of the noise-decoupled spectrum which makes ^{13}C spectroscopy so valuable is that each carbon atom of the sample gives a separate line. Unlike ^1H spectroscopy, overlap of resonance signals is less frequently observed because, whereas the chemical shift range for ^1H is about 10 ppm, the chemical shift range for ^{13}C is about 230 ppm. By making use of the multiplicities of the off-resonance decoupled spectrum (Fig. 9B) and taking account of shielding effects of functional groups, all the signals in the spectrum can be assigned (Table 2).

Fig. 9. ^{13}C spectrum of pilocarpine nitrate (10% solution in deuterium oxide). A, fully noise-decoupled; B, off-resonance noise-decoupled.

Table 2. Assignments of ^{13}C spectrum of pilocarpine nitrate

Chemical shift relative to TMS δ ppm	Multiplicity	Assignment carbon number
14.2	quartet	11
20.6	triplet	10
23.5	triplet	5
36.1	quartet	1
38.8	doublet	6
47.2	doublet	9
73.9	triplet	7
119.5	doublet	3
135.1	singlet	4
137.9	doublet	2
184.6	singlet	8

APPLICATIONS

Nuclear magnetic resonance spectroscopy is complementary to infra-red and ultraviolet spectrophotometry, and mass spectrometry, as a method for identification of drugs. Infra-red and ultraviolet spectrophotometry are used to identify functional groups but NMR is mainly used to study the molecular structure around the functional groups. Differences in chemical shifts are often due to the influence of the substituents on their surrounding hydrocarbon skeleton and, by studying coupling systems, much valuable information is obtained on how the various parts of this skeleton fit together.

Drug Metabolism Studies

The concentration of metabolites in samples of body fluids is usually low but, in spite of its low sensitivity, NMR has made a valuable contribution to the study of drug metabolism.

However, conjugation reactions, especially glucuronide formation, have not been studied as much as other routes of metabolism, mainly because of the poor solubility of these conjugates in commonly used solvents. Aromatic and aliphatic hydroxylations are processes which are very common during the metabolism of drugs and NMR can often provide a means of identifying the position of the hydroxyl group on a molecule by analysing the coupling systems of the remaining aromatic protons thus revealing the substitution pattern of the metabolite. This is illustrated in a study of 4-chlorobiphenyl, which produced two metabolites. They were shown by mass spectrometry to contain one and two phenolic groups, respectively, and NMR was used to determine their positions. In one case the aromatic protons appeared as four sets of doublets with the same coupling constants, which is typical of an *ortho* coupling, and one metabolite was therefore

identified as 4'-chlorobiphenyl-4-ol. The other metabolite contained two hydroxyl groups and gave a signal due to a proton indicating an *ortho* coupling, another signal due to a proton indicating a *meta* coupling, and a third signal due to a proton indicating an *ortho* and a *meta* coupling. This helped to identify the second metabolite as 4'-chlorobiphenyl-3,4-diol (S. Safe *et al.*, *J. Chem. Soc., Perkin Transactions I*, 1976, 357-359).

Identification

Nuclear magnetic resonance spectroscopy can be used to distinguish between the phosphate esters of steroids. The free steroids can be distinguished by infra-red spectrophotometry, but the phosphate esters are sufficiently polar to give rise to absorption bands that dominate the IR spectra and make distinction difficult. The NMR spectra of these steroid esters are not subject to this interference, and although they may be very difficult to interpret, they do provide the necessary distinction.

A similar situation arises in the case of the aminoglycoside antibiotics framycetin sulphate, kanamycin sulphate and acid sulphate, gentamicin sulphate, and tobramycin. Their infra-red spectra are dominated by hydroxyl and amino absorptions of the amino sugar and, except for tobramycin, by sulphate absorptions. The proton spectra however contain sufficient differences to distinguish them.

Determination of Water Content

NMR may also be used as a test for the water content of a drug such as cloprostenol, since water shows a resonance signal at δ 4.72 ppm. However, cloprostenol contains three hydroxyl groups and when the spectrum is recorded in deuterium oxide, the protons of these hydroxyl groups rapidly exchange with deuterium of the solvent and therefore contribute to this δ 4.72 ppm resonance.

To compensate for this contribution the olefinic resonances are used as an internal standard. Cloprostenol possesses four olefinic protons, two from the 5-*cis*-olefin and two from the 13-*trans*-olefin which give rise to an overlapping multiplet between δ 5.2 and δ 5.8 ppm. The integrated intensity of this multiplet is equivalent to four protons and so by subtracting 0.75 of this value from the integrated intensity of the δ 4.72 ppm peak the three hydroxyl groups are accounted for and the remainder is due to water.

Forensic Applications

NMR has become established as a useful tool in forensic science and some references to this application are cited in the Bibliography.

An example of the use of NMR in forensic science is the identification of four 5-ethyl-5-alkyl substituted barbiturates, butobarbitone, pentobarbitone, secbutobarbitone, and amylobarbitone. The proton spectra of all four barbiturates show a very broad signal at around δ 8 ppm to δ 10 ppm which is characteristic of amido protons. The useful region of the spectrum for the differentiation of these barbiturates lies between δ 0.5 and δ 2.5 ppm due to the substituents on C₅. There are three groups of multiplets in this region and the data for these groups for the four barbiturates are presented in Table 3.

Group 1 may be assigned to methylene and (or) methine protons on carbon atoms directly attached to C₅ and are the most deshielded protons as they are β to two carbonyl groups. Group 2 may be assigned to the central methylene and (or) methine protons of the alkyl chains. Group 3 may be assigned to the methyl groups. Analysis of the signals in these groups provides unequivocal identification of the four barbiturates.

Table 3. Data from NMR spectra of barbiturates

	Group 1 δ 1.6 ppm to δ 2.5 ppm		Group 2 δ 1.2 ppm to δ 1.6 ppm		Group 3 δ 0.5 ppm to δ 1.2 ppm	
	Relative number of protons	Multiplicity	Relative number of protons	Multiplicity	Relative number of protons	Multiplicity
Butobarbitone	4	skewed quartet	4	multiplet	6	triplet with fine coupling
Pentobarbitone	3	quartet	4	multiplet	9	quartet with fine coupling
Secbutobarbitone	3	quartet	2	multiplet	9	quartet with fine coupling
Amylobarbitone	4	skewed quartet	3	multiplet	9	triplet

Pharmacokinetics, Metabolism, and the Interpretation of Results

W. J. Tilstone and A. H. Stead

In order to interpret the analytical results in a toxicological investigation, it is necessary to have a knowledge of drug disposition and metabolism. A variety of questions may be put to the toxicologist, including 'What drug was taken?', 'What was its dose?', 'By which route and when was it taken?', 'Was the observed pharmacological response a result of chronic or acute exposure to the drug?', and 'Can the response be explained in terms of the drug concentration found?'. A knowledge of the aspects of anatomy and physiology which determine the absorption, distribution, and elimination of drugs from the body, together with an understanding of drug metabolism, will allow these questions to be answered with a fair degree of confidence.

Basic Concepts of Pharmacokinetics

The onset, duration, and intensity of action of a drug after administration are controlled by the rate at which the drug reaches its site of action and by the concentration of the drug at the receptor. The physiological disposition of a drug is controlled by the three major processes of absorption, distribution into and within tissues, and elimination. Pharmacokinetics is a mathematical consideration of these processes which relates the dose given, the concentration in the blood, and the pharmacological response.

Most drugs given by intravenous injection or by mouth will give blood (or plasma) concentration-time curves of the type shown in Fig. 1A and Fig. 1B, respectively. Following intravenous administration, there is a rapid decrease in plasma-drug concentration in the early period (α -phase) when distribution is the major process, followed by a slower, constant rate of decrease in the elimination phase (β -phase). After oral administration, plasma concentrations initially increase whilst the drug is being absorbed and then decrease when elimination becomes the major process.

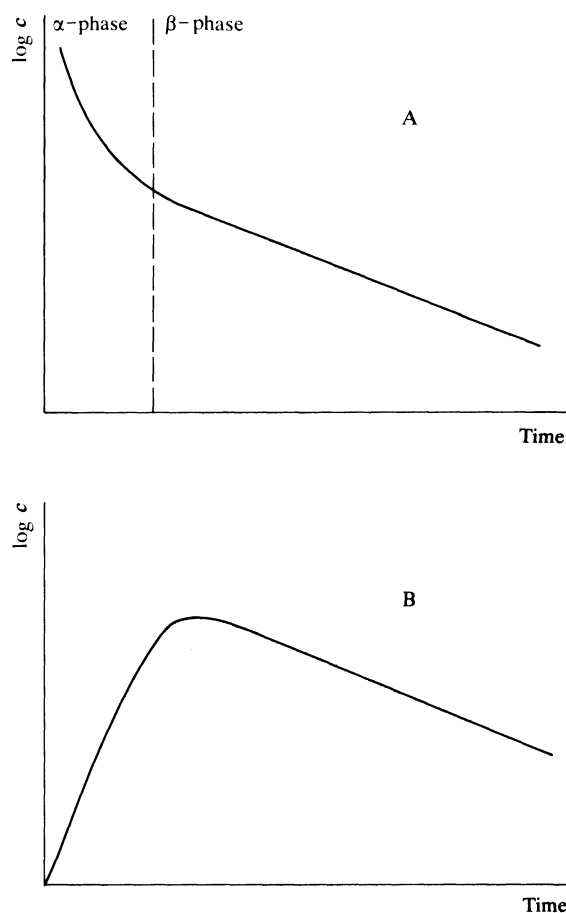

Fig. 1. Typical semilogarithmic plots of plasma concentration (c) versus time for a drug given A, by intravenous injection, and B, orally. The terminal rate of decline of plasma concentrations is the same irrespective of the route of administration.

ABSORPTION

To produce an effect, a drug must first enter the blood stream and be carried to the target organ. With the exception of intravenous injection, the first process is that of absorption, either from the gastro-intestinal tract, from an injection site, or from the lungs.

The route of administration is an important factor in determining the rate and extent of absorption. For example, absorption after an oral dose can be relatively slow and erratic, whilst absorption from the lungs is usually fast because of the good blood supply. Most drugs are administered orally, and an understanding of the mechanism of absorption by this route is by far the most important for the toxicologist.

Absorption from the Gastro-intestinal Tract

The traditional way of describing drug absorption is by the pH-partition hypothesis. This hypothesis regards the passage of a drug into the blood as being by passive diffusion of non-ionised molecules across the lipid barrier of the cells of the gut lining and into the blood. Complex factors control the release of a drug from a pharmaceutical preparation, but apart from this the hypothesis is an oversimplification because the gastro-intestinal wall is not a single lipid membrane but rather a layer of cells. According to the hypothesis, an acid drug such as aspirin (pK_a 3.5) is absorbed in the stomach at about pH 2 when the drug is non-ionised. The drug diffuses passively across a single barrier into the capillaries and is taken up by the plasma at pH 7.4. Here, it ionises and is therefore unable to return to the stomach because there is a net concentration gradient of 25 000 to 1, stomach to plasma, of the non-ionised species. In practice, aspirin is not totally absorbed in the stomach due to the poor blood supply and small surface area. Basic drugs such as ephedrine (pK_a 9.6) are only slightly absorbed in the stomach, the major part being absorbed from the upper section of the small intestine (pH 5 to 7), the lower section (pH 7 to 8), or from the colon (pH 7 to 8).

However, contrary to the hypothesis, the absorption of ionised species also occurs. For example, paraquat is highly ionised but appears to be absorbed slowly from the gastro-intestinal tract throughout its length and over a considerable period of time from the moment of ingestion. Poisoning with such compounds can be treated effectively by the prompt administration of an oral adsorbent which prevents further absorption of the drug.

Absorption generally depends very much on the large difference in drug concentration between the gastro-intestinal tract and the blood. A knowledge of the blood flow to the different parts of the gastro-intestinal tract and of the pH of its contents is therefore important. These factors, together with the surface areas available for absorption and the

gastro-intestinal transit times are shown in Fig. 2. Absorption is possible throughout the gastro-intestinal tract, from stomach to rectum, although the major site is the upper small intestine. This has high peristalsis, a high surface area, high blood flow, and optimal pH for the absorption of most drugs, all of which result in a high absorption rate. Drug absorption tends to be much less rapid from other parts of the tract.

Bioavailability

The extent to which a drug is absorbed from its site of administration into the systemic circulation is known as its (absolute or systemic) bioavailability (F). It is determined experimentally from the ratio

$$F = \frac{\text{AUC (extravascular)}}{\text{AUC (intravenous)}}$$

where AUC (the area under the plasma concentration-time curve) represents the amount of drug entering the systemic circulation during t_0 to t_∞ for a single dose, or at steady state, within a given dose interval. The bioavailability is simply the fraction of the drug dose which is absorbed intact by any given route compared with intravenous administration, which gives the equivalent of 100% absorption. Although absolute bioavailability requires reference to an intravenous standard, the relative bioavailabilities of formulations can be determined using other routes of administration. The effects of the first passage of a drug through the liver (first-pass metabolism) are explained on p. 281.

Enterohepatic Circulation

Drugs and metabolites which are eliminated from the liver into the bile subsequently pass into the lumen of the gastro-intestinal tract. Such compounds, usually of relatively high molecular weight (>500), and containing a hydrophilic residue in the molecule (e.g. digitoxin), may then be reabsorbed either directly or indirectly following further metabolism. This recycling of drugs is known as enterohepatic circulation. Glucuronide conjugates of drugs which are excreted in significant amounts in the bile, such as morphine, may be hydrolysed by the intestinal microflora and reabsorbed. Enterohepatic circulation thus prolongs the persistence of a drug in the body and may lead to delayed toxicity, or to toxicity arising from the absorption of a drug metabolite produced by intestinal bacteria. Drugs which undergo enterohepatic circulation may be detected in the faeces in unchanged form even if they have been administered by a parenteral route.

<i>Organ</i>	<i>pH</i>	<i>Surface area</i>	<i>Blood flow*</i>	<i>Motility and transit time of contents</i>
Stomach†	1–3	< 5 m ²	Rises on stimulation of gastric secretions	Relatively 'quiet'. Transit time of contents depends on their chemical and physical nature, including pH and osmotic pressure. Placed in order of increasing transit times, liquids < solids; carbohydrates < proteins < fats. Times vary from 0.5 h for a small amount of liquid carbohydrate to 20 h for a large fatty meal.
Small intestine, S	S1, 5–7 S2, 7–8	200 m ²	Very fast counter-current flow in villi. Blood transit time—1 s after meals; 5 s resting; 30 s in shock	Food churned, and propelled by very active movements in waves, by both peristalsis and by segmentation. Transit time—about 2 h.
Colon, C	7–8	< 5 m ²	Average	Residues of meals found at C1 after 4 h, C2 after 6 h, C3 after 9 h, and C4 after 12 h. Residues are held up in the rectum (C5) and then egested in faeces over a period of time. Earliest traces may be egested within 6 h, the last may take 1 week. On average 75% of residues are egested by the 3rd day.

*Average is 36 ml/min per 100 g intestine, 50–75% of which circulates in the mucosal layers
†The volume of the stomach can change markedly: 50 ml during fasting and up to 2 litres when full

Fig. 2. Factors which influence the passage and absorption of drugs in the gastro-intestinal tract.

DISTRIBUTION

After a drug has been absorbed, i.e. after it has passed from the gastro-intestinal tract, through the liver, and into the systemic circulation, it is then distributed throughout the body. Distribution depends on a number of factors. These include the blood flow to the tissues, the partition coefficient of the drug between blood and the tissue, the degree of ionisation of the drug at the pH of plasma, the molecular size of the drug, and the extent of tissue and plasma protein binding. For example, the distribution of plasma protein-bound drugs such as the warfarin-type anticoagulants is restricted to plasma and extracellular fluid, whereas alcohol distributes equally into the total body water. The approximate volumes of the body water

compartments for a person of average weight are: intracellular water 25 litres and extracellular water 17 litres (of which 3 litres is plasma water). An intravenous dose of a drug which is distributed immediately into the total body water (approximately 42 litres) would give an initial plasma concentration (dose divided by 42) approximately two-fifths of that obtained if the same dose was distributed only into extracellular water (dose divided by 17). If the drug is extensively bound to tissue proteins, an even lower initial plasma concentration would be obtained, and the volume term relating the dose to the plasma concentration could exceed the volume of the body. The approximate proportions of weights and water contents of the various body tissues are given in Tables 1 and 2.

Table 1. Comparison of weights of tissues and water content in the average adult male

	% Body weight	% Water
Muscle	40	76
Fat	10	10
Liver	2.5	68
Brain	2	75
Lungs	0.7	79
Kidneys	0.4	83

	Male	Female
10–18	59	57
18–40	61	51
40–60	55	47
> 60	52	46

Volume of Distribution

A full description of drug distribution can be complex, whether it is based on a knowledge of tissue perfusion and partition of drug from plasma to tissue, or whether it is based on a kinetic analysis of plasma concentration-time curves. One of the major descriptive parameters, which is probably of most interest to the toxicologist, is the volume of distribution (V_d). This is the amount of drug in the body (A) divided by the plasma concentration (c) after distribution equilibrium has been established,

$$V_d = \frac{A}{c}$$

The drug concentration in body fluids other than plasma may be used, e.g. whole blood, but different values for V_d are obtained for each; it is extremely important, therefore, to note which fluid is being used. In the monographs in Part 2, volumes of distribution, unless otherwise stated, are based on plasma concentrations.

The value of the volume of distribution is determined mainly by the physiological processes of perfusion and protein binding, but it seldom has a true physiological meaning. For example, the volume of distribution of frusemide, a drug which is highly bound to plasma albumin, is of the order of 15 litres, and that of alcohol is about 35 litres; however, the value for digoxin, which is extensively distributed and bound in extravascular tissues, is of the order of 450 litres.

After distribution equilibrium has been established, a knowledge of the volume of distribution allows the amount of drug in the body to be estimated from a single measured blood concentration

$$A = V_d c$$

If the time elapsed since drug administration (t) is known, together with some pharmacokinetic data for the drug, then it should be possible to estimate the original dose (D) of the drug. Thus, for a drug given by intravenous injection,

$$D = V_d c e^{k_{el} t}$$

where k_{el} is the elimination rate constant (see p. 281). However, if the drug is given orally, a much more complex relationship applies. It is necessary to know the bioavailability (F), and the absorption rate constant (k_a). Then the dose is given by the expression

$$D = \frac{V_d c (k_a - k_{el})}{F k_a} \cdot \frac{1}{e^{-k_{el} t} - e^{-k_a t}}$$

If a drug were distributed instantaneously throughout the body, then the volume of distribution would be constant at all times and the decrease in plasma concentration could be attributed solely to elimination of the drug. However, in practice there is a rapid initial decrease in plasma concentration largely due to distribution of the drug into the tissues. This distribution phase (α -phase) lasts approximately 30 minutes to 2 hours for most drugs. During this phase, although the total amount of drug in the body remains virtually constant, the volume of distribution changes continually. It only remains constant when the decrease in plasma concentration is due only to elimination because distribution is complete. The elimination phase (β -phase) is characterised by a slower decline in plasma concentration which is accompanied by a parallel decline in tissue concentrations.

It is generally assumed that absorption, metabolism, and elimination follow first-order kinetics, i.e. the rate at which the process proceeds is dependent solely on the concentration of the drug. Occasionally, the rate is limited by saturation of the body's capacity to process the drug. An increase in the drug concentration does not affect the rate in such cases and the process is said to follow zero-order kinetics. When it is assumed that the equilibrium between concentrations of the drug throughout the body and plasma is attained instantaneously, the body is regarded as a single homogeneous entity. The use of this one-compartmental model of the body (and

assuming first-order kinetics) simplifies the mathematics involved in describing the pharmacokinetics of a drug. When distribution is not instantaneous throughout the body, more complex multi-compartmental models are required to describe adequately the fate of the drug. Fig. 1A illustrates a biphasic plasma concentration-time curve and it would be appropriate to use the two-compartmental model of the body in this case. In general, only highly perfused tissues such as the liver and kidneys have tissue drug concentrations in instantaneous equilibrium with those in plasma. Distribution of a drug into and out of poorly perfused tissues such as muscle and fat is discernible in the plasma concentration-time curve of the drug, and requires a separate compartment for adequate pharmacokinetic treatment. Less frequently, further subdivision into rapidly- and slowly-distributing tissues is also required.

Evaluation of the volume of distribution becomes difficult in the case of a drug which requires a model with two or more compartments to describe its disposition. One method of determining the final volume of distribution is to extrapolate the terminal linear part of a semilogarithmic plot of plasma concentration-time to the point $t=0$, but this treatment yields an inaccurate figure. One of the best ways to determine the volume of distribution when the drug is in the β -phase (V_β) is to use the relationship

$$V_\beta = \frac{D}{\beta \int_{t=0}^{\infty} c \cdot dt}$$

where β is the terminal elimination rate constant. This expression, sometimes known as V_{area} , be used to relate plasma-drug concentration to the amount of drug in the body for a two-compartmental drug which is in the β -phase, or indeed at any time for the one-compartmental model when β is replaced by the elimination rate constant k_{el} in the above expression.

Distribution of Drugs to Tissues

The instantaneous equilibrium of drug concentrations throughout the body as considered above does not necessarily require that the concentrations are equal throughout the body. In fact, drug concentrations in tissues are rarely equal to those in plasma. For example, the tissue: plasma concentration ratio will be very low immediately following intravenous administration. As time progresses, the amount of

drug in the tissue compartment will increase and, like that in the plasma compartment, will eventually reach a plateau. If the drug is actively stored in a particular tissue compartment, then the ultimate concentration ratio between the tissue and plasma will be relatively high. It should also be noted that the tissue: plasma concentration ratio depends not only on the processes of distribution, but also to a large extent on the route of drug administration, and on whether single or multiple doses have been given.

ELIMINATION

Most drugs are eliminated from the body by metabolism in the liver and/or by excretion of the drug and its metabolites by the kidneys. However, metabolism and elimination by other tissues such as the lungs may occur, as well as excretion of drugs and metabolites in the bile.

Clearance

The elimination of drugs from the body can be described quantitatively using the concept of clearance, and this can be related to physiological events.

Overall, the efficiency of elimination by an organ can be expressed as the proportion of drug entering the organ which is eliminated from the plasma in a single passage; this is called the *extraction ratio*. The other major factor which controls the overall ability of an organ to remove drug from the body is the rate of delivery of the drug (i.e. blood flow) to the organ. Drug elimination can be represented as the product of this rate of delivery and the extraction ratio. This product gives the volume of plasma from which drug is completely removed per unit time and is given the name clearance (Cl). Clearances by different organs are additive. Although the reference fluid normally used is plasma, whole blood may also be used.

In the monographs in Part 2, clearance has been included where possible and usually refers to the total plasma clearance (or total whole blood clearance) after intravenous administration. In some instances, the total clearance calculated after oral administration has been included if the drug is known to be well absorbed and is not subject to significant first-pass metabolism.

The concept of clearance has found particular application in clinical work as it offers a simple relationship between dose rate (dose divided by the time interval between doses, D/τ), and the average plasma concentration (\bar{c}) of the drug

$$\tilde{c} = \frac{D/\tau}{Cl}$$

The efficiency of an eliminating organ in removing drug from plasma depends on the health of the organ. Thus, diseased kidneys operate less efficiently, and the net change in clearance is proportional to the extent of renal impairment.

Despite its clinical utility, the concept of clearance has certain limitations for the forensic toxicologist because it does not give an immediate indication of the persistence of a drug in the body. For example, although gentamicin and digoxin have similar clearances (about 100 ml/min), digoxin will stay in the body much longer than gentamicin. This is because the volume of distribution of digoxin is several times that of gentamicin, and there is therefore a much greater volume of fluid from which the drug must be cleared before it is all eliminated. It is therefore of some advantage to the toxicologist to be able to relate clearance to the persistence of a drug in the body. This can be done by expressing clearance as a fractional clearance, i.e. clearance divided by the volume of distribution. Fractional clearance (Cl/V_d) has the dimension reciprocal time and represents the proportion of drug removed from the body per unit time, i.e. it is a first-order rate constant for drug elimination (k_{el}). This rate constant is given by the gradient of the terminal part of the concentration-time curves shown in Fig. 1.

Half-life

The half-life of a drug ($t_{1/2}$) is the time required for plasma concentrations to decline by 50%, provided that elimination occurs by a first-order process (Fig. 3). It is related to the elimination rate constant (k_{el}) by the equation

$$t_{1/2} = \frac{0.693}{k_{el}}$$

The half-life of a drug provides a measure of the rate of irreversible drug loss from the blood. If the dose is known, the half-life of a drug can be used together with information on the volume of distribution, and bioavailability where necessary, to estimate the time elapsed since administration. Conversely, if the elapsed time is known, the half-life can be used to estimate the drug dose. The half-life is a function of both volume of distribution and clearance, the proportion of drug elimination in unit

Fig. 3. Plot of natural logarithm of plasma drug concentration ($\ln c$) versus time (t) following intravenous administration. The gradient of the linear part of the curve is equal to the elimination rate constant (k_{el}).

time depending on both the extent of its distribution and on the efficiency of its elimination. Thus the half-life of a drug may differ between children and adults because of size and weight, even though the clearances are equivalent.

Elimination by the Liver

The principal pathways of drug elimination involving the liver are shown in Fig. 4. The drug may enter the liver from the general circulation via the hepatic artery (approximately 300 ml of blood per minute), or via the portal vein (approximately 1000 ml of blood per minute) from the gastro-intestinal tract. The concentration of drug in the hepatic artery during the absorption phase can be several orders of magnitude less than that in the portal vein. Drugs in the liver are immediately exposed to the metabolic enzyme systems. Thus, drugs which are absorbed from the gastro-intestinal tract into the portal vein may undergo metabolism in the liver before reaching the general circulation. The effect is known as *first-pass metabolism*. It results in a low and extremely variable fraction of an oral dose reaching the systemic circulation. First-pass metabolism is responsible for much of the inter- and intra-individual variations in blood concentrations and in the pharmacological responses observed for many drugs of clinical and forensic interest (e.g. aspirin, dextropropoxyphene, imipramine, morphine, paracetamol, and propranolol). Drugs are removed

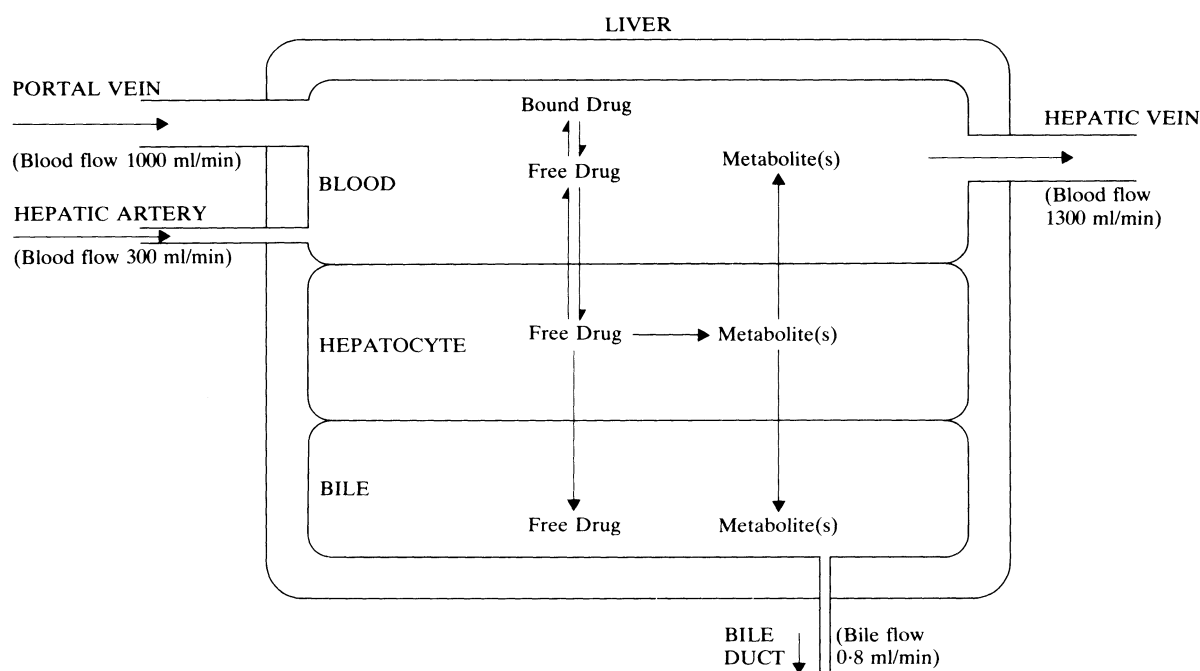

Fig. 4. Drug elimination by the liver.

from the liver as metabolites or as unchanged drug, either by biliary secretion (flow rate approximately 0.8 ml/min), or in the hepatic vein (approximately 1300 ml of blood per minute). Some drugs and metabolites, e.g. morphine glucuronide, are excreted in the bile in high concentrations.

Elimination by the Kidneys

The significant factors in renal drug elimination are shown in Fig. 5. The drug is brought to the kidneys with a total plasma flow for both kidneys of approximately 1400 ml/min. The plasma is filtered at the rate of 125 ml/min in the glomeruli, which are the principal site of excretion. Filtration is passive and only non-protein-bound drug in the plasma is eliminated by this pathway. A considerable amount of filtered drug may be reabsorbed into the plasma by diffusion back across the tubule wall (which is permeable to non-ionised, lipid-soluble species). This is because the drug concentration in the filtrate in the lower parts of the tubule is higher than that in the plasma. The filtrate (125 ml/min) is gradually concentrated as it passes down the tubule to give a final production of urine of about 1 ml/min. About

575 ml/min of plasma circulates in intimate contact with the proximal and distal renal tubules.

The renal tubule may contribute to elimination by active secretion, and in such cases protein-bound drug may also be eliminated from the plasma.

The extent of elimination by the kidneys can be extremely variable depending on which of the three processes of filtration, secretion, or reabsorption predominates for the drug in question. Thus, procainamide is eliminated partly by metabolism and partly as unchanged drug through the kidney. Its renal clearance is of the order of 450 ml/min, indicating major involvement of tubular secretion. By contrast, digoxin has a renal clearance of about 120 ml/min, and this could be explained by either filtration alone, or by the fact that secretion is balanced by reabsorption. In practice, it is known that filtration accounts for almost all of the renal clearance of digoxin. A further example is metha-qualone, which has a renal clearance of about 1 ml/min, clearly indicating extensive reabsorption of filtered drug.

The principal factor which determines the variability in the rate of drug excretion into the urine, other than organ function and blood flow, is the pH of the urine. Only non-ionised species are available

Fig. 5. Drug elimination by the kidneys. Schematic diagram of a nephron to illustrate the sites of filtration, diffusion, and active secretion of drugs.

for reabsorption by the tubules along the concentration gradient. Thus, acidic drugs (e.g. barbiturates, salicylates) are excreted more rapidly at high pH than basic drugs (e.g. amphetamines). Conversely, basic drugs are excreted more rapidly at low pH. For example, about 85% of a dose of aspirin is excreted as free salicylic acid in alkaline urine, but only about 5% is excreted when the urine is acidic. Conversely, about 75% of a dose of amphetamine is excreted unchanged in acidic urine but less than 5% if the urine is alkaline.

The effect of varying urinary pH has been used in the treatment of drug overdose by applying forced alkaline diuresis as an adjunct to the treatment of salicylate or phenobarbitone poisoning. The success of the treatment is limited by the extent to which these drugs are distributed, and by the presence of

alternative pathways of elimination. There is a general limitation to the success of treating an overdose by increasing drug clearance because a highly-distributed drug will have a relatively long half-life; any increase in clearance will not make much difference to its persistence.

Persons who abuse amphetamines have used the effect of urinary pH on excretion by simultaneously ingesting bicarbonate. This produces an alkaline urine which delays elimination of the amphetamine and therefore prolongs its stimulant effect. Conversely, substances which acidify urine have been taken by athletes to enhance elimination of amphetamine-like stimulants in the hope of avoiding detection in routine dope-screening procedures. Exercise in itself can also decrease urinary pH and thus increase the renal clearance of basic drugs. Where pH is known to have a significant effect on the disposition and elimination of a drug, this has been noted in the monographs in Part 2.

Despite these complications, there is in general a relationship between the concentration of a drug in plasma, its plasma clearance, and its excretion rate by any particular mechanism. The relationship is one of simple proportion, in that the excretion rate is equal to the product of the plasma concentration and the renal clearance. The higher the plasma concentration and the greater the clearance by a particular mechanism, the greater will be the excretion rate of a drug by that mechanism. Thus, the quantity of drug in a urine sample is the product of the renal clearance of the drug, the average plasma concentration of the drug during the interval that the urine was produced, and the duration of that interval. This relationship is one of the fundamental principles of pharmacokinetics, and shows that if a drug has a constant renal clearance, there is no direct relationship between the plasma concentration and the urine concentration because urinary flow rate must also be considered. However, for drugs which are extensively reabsorbed, renal clearance may not be constant but will tend to vary with the urine flow. In these cases, there is a relationship between the concentration in urine and the concentration in plasma.

In general, the interpretation of urine data in terms of plasma concentrations is a difficult procedure. An approximate working relationship can be determined because the daily urine output is usually fairly constant at about 1500 ml per day (1 ml/min), in healthy adults. Under these circumstances, the

amount of drug in a urine sample collected over a short interval will be equal to the product of the renal clearance of the drug and its average concentration in plasma during that interval. If the renal clearance is known, the approximate plasma concentration can be calculated from the urine concentration (or vice versa). As most drugs normally have a renal clearance greater than 1 ml/min, average drug concentrations in urine for any time interval will exceed those in plasma. For such drugs, urine is a relatively good sample for drug screening procedures. However, for drugs which are eliminated very rapidly, the mean plasma concentration over a day would be negligible. The mean urine concentration would also be low, and the collection of urine over 24 hours would be pointless.

If the renal clearance of a drug varies with urine flow, as with an extensively reabsorbed neutral drug such as methaqualone, then there may be a random sequence of positive and negative findings during the analysis of consecutive urine samples. In view of these difficulties, the interpretation of analytical data from urine samples alone should not be attempted unless urine is the only fluid available and there is some other information which will allow an estimate of the dose to be made.

Drug Accumulation

Drugs accumulate in plasma or tissues if more than one dose is administered and the interval between doses is less than the time taken to eliminate the previous dose. Under these circumstances, there will also be a change in the shapes of the plasma concentration-time and the tissue concentration-time curves. In all cases, accumulation is controlled by the size of the dose, the dose interval, and the first-order elimination rate constant for loss of drug from the body (k_{el}). The problems of drug accumulation are of particular interest to the toxicologist because the resulting high drug concentrations may lead to a progressive and insidious toxicity.

The extent to which a drug will accumulate in multiple dosing can be estimated. After each successive dose, the maximum, minimum, and average plasma concentrations will be higher than those for the previous dose. This is so in the early stages, but since drug elimination is a first-order rate process, the total amount of drug in the body will increase until the amount eliminated during a dose interval equals the amount taken in (total injected dose or the net absorbed dose after oral dosing). At this so-called *steady state*, the average plasma

concentration is equal to the dose rate divided by the clearance of the drug. The accumulation ratio relates the average amount of drug in the body at steady state (A_{ss}) and the dose (D)

$$\frac{A_{ss}}{D} = \frac{1.44 t_{1/2}}{\tau}$$

where τ is the dosage interval.

Drug Metabolism

Metabolism is an integral part of drug elimination. As well as facilitating excretion of a drug, it may also affect the pharmacological response of a drug by altering its potency and/or duration of action. When a lipid-insoluble, polar, or ionised drug is absorbed into the body it is largely excreted unchanged by the kidneys. However, the majority of drugs are lipid-soluble to some extent and are reabsorbed into the blood from the glomerular filtrate. They need to be converted to a more polar (water-soluble) form before they can be excreted in the urine. Such compounds often undergo extensive metabolism. Metabolites are usually excreted in the urine although large proportions of the glucuronides of some drugs (e.g. morphine and codeine) are eliminated in the bile.

Although the metabolic process is usually regarded as one of detoxification, this is not always so and metabolites which are more toxic than the parent drug are known. Metabolites may be pharmacologically inactive (e.g. the hydroxylated derivative of phenobarbitone) or they may be active with different pharmacokinetic properties but similar modes of action to the parent drug. This is the case with many psychotropic drugs. For example, hydroxylation and demethylation of the tranquilliser diazepam gives the metabolites temazepam and oxazepam, both of which are also marketed as drugs in their own right. Similarly, amitriptyline, a tricyclic antidepressant, is demethylated to yield another antidepressant, nortriptyline. Active metabolites may also have different modes of action or different potencies; thus dealkylation of the antidepressant drug iproniazid gives the tuberculostatic drug isoniazid, while the anticonvulsant drug primidone is metabolised to phenobarbitone, another anticonvulsant which has a much longer duration of action.

Pathways of drug metabolism are conventionally divided into two groups, non-synthetic and synthetic. The *non-synthetic routes* are principally oxidation

(including hydroxylation, *N*- and *O*-dealkylation, and sulfoxide formation) and to a lesser extent reduction and hydrolysis. These are generally referred to as Phase I reactions. The *synthetic routes* mainly involve conjugation with glucuronic acid, but acetylation, methylation, and conjugation with amino acids and sulphate also occur. These are usually referred to as Phase II reactions. Phase II reactions remove or mask functional groups (e.g. amino, carboxyl, hydroxyl, sulphhydryl, etc.) on the drug or Phase I metabolite by the addition of an endogenous substrate. In this way Phase I and Phase II reactions are frequently associated with each other, although this is by no means a prerequisite. The major Phase II reaction is conjugation of glucuronic acid with the phenolic or alcoholic hydroxyl groups which are common products of Phase I reactions. Conjugation reactions usually result in a reduction of toxicity and can therefore be referred to as genuine detoxification mechanisms.

Despite the extensive range of reactions which a drug molecule can undergo, the majority are catalysed by microsomal membrane-bound enzymes in the hepatocytes (parenchymal cells of the liver). For example, the cytochrome P-450 mixed function oxidase system which catalyses oxidations, and glucuronyl transferase, the enzyme responsible for conjugation with glucuronic acid, are both located on microsomal membranes. However, some metabolic pathways employ non-microsomal enzymes or those which are not bound to membranes. For example, oxidative deamination of a number of drugs is performed by monoamine oxidases which are widely distributed in the mitochondria; acetylation, an important metabolic pathway for some drugs, is carried out by the non membrane-bound acetyltransferase found in intracellular fluids. Metabolism can occur in tissues other than the liver; the gastro-intestinal tract, kidneys, and lungs may have a significant effect on the metabolism of a drug depending on its route of administration. For example, many metabolic reactions occur in the gastro-intestinal tract before an orally-administered drug is absorbed, carried out by enzymes in the mucosal lining or by microflora. Most of these reactions involve reduction and hydrolysis because of the anaerobic environment. Plasma esterases cause extensive hydrolysis of drugs such as cocaine and procaine.

An individual drug may be extensively metabolised, and may undergo several completely different reactions. Thus, chlorpromazine gives rise to

at least twenty metabolites by its three major routes of metabolism, i.e. hydroxylation, *N*-demethylation, and sulfoxidation. Fortunately, such complicated patterns of metabolism are not a major problem to the analyst since most metabolites occur only in very small amounts.

Using drugs principally of forensic interest, a number of examples are given below to illustrate the variety of metabolic routes which can be followed in man and the effects that these might have on disposition and pharmacological activity. The list is not intended to be exhaustive with regard to either the pathways or the drugs covered. Oxidation reactions are emphasised as these occur most frequently, yielding metabolites which are commonly conjugated before excretion.

Oxidation Reactions

All the major oxidative mechanisms can be illustrated by considering the metabolism of the barbiturates, benzodiazepines, amphetamines, tricyclic antidepressants, phenothiazines, and opiates.

BARBITURATES

The barbiturates are derivatives of barbituric acid and have the general structure given below. The nitrogen atom at position 1 may be methylated. Substitution of sulphur for oxygen at position 2 gives the thiobarbiturates.

The barbiturates can be metabolised by five major routes: (1) hydroxylation of alkyl and aryl substituents at C₅ (e.g. pentobarbitone and phenobarbitone); (2) *N*-dealkylation at the *N*¹-position (e.g. methohexitone); (3) oxidation of alkyl groups at C₅ to give carboxylic acids (e.g. thiopentone); (4) desulphuration at C₂ (e.g. thiopentone); and (5) oxidative ring fission at the 1:6 position (e.g. amylobarbitone).

The major metabolic pathway of the 5,5-disubstituted barbiturates is hydroxylation, usually of the larger of the two substituents, e.g. the phenyl group in phenobarbitone, the 1-methylbutyl group in pentobarbitone, and the alicyclic group in cyclobarbitone. Hydroxylation of aliphatic groups at the C₅ position is usually at the ω-1 (penultimate)

position, giving oxygenated products which are further oxidised to ketones. Hydroxylation of aliphatic groups at the ω position can also occur, usually giving products which undergo further oxidation to the corresponding carboxylic acid. With the exception of 3'-hydroxyamylobarbitone, all hydroxylated metabolites have little or no hypnotic activity. Desulphuration to the ketone and *N*-dealkylation are general routes of metabolism of thiobarbiturates and *N*-alkyl barbiturates, respectively; both reactions occur to a variable extent. Ring fission of barbiturates to give substituted malonylureas appears to be only a minor reaction. Most barbiturates are extensively metabolised; for example, less than 5% of a dose of amylobarbitone, quinalbarbitone, or pentobarbitone is excreted unchanged in urine. However, with phenobarbitone (the least lipid-soluble of the common barbiturates) about 25% of a dose is excreted unchanged, and the highly water-soluble barbitone is excreted almost entirely unchanged.

The metabolism of amylobarbitone is illustrated below; ω -1 hydroxylation is the major metabolic reaction producing 3'-hydroxyamylobarbitone which can be detected in urine five days after administration of a 100-mg dose. This is in contrast to the unchanged drug which can only be detected

for the first two to three days. Practically none of the hydroxy metabolite is excreted as the glucuronide or other conjugate.

Hexobarbitone illustrates a variety of the metabolic transformations which the barbiturates undergo, including 1:6 ring fission (see below).

BENZODIAZEPINES

The benzodiazepines, one of the most widely prescribed groups of drugs, undergo extensive metabolism by routes already described for the barbiturates, namely *N*-dealkylation and hydroxylation. However, unlike the barbiturates, metabolic conversion yields derivatives which have similar pharmacological activities and potencies to those of the parent compounds. For example, the three major metabolites of diazepam are desmethyldiazepam (nordazepam), 3-hydroxydiazepam (temazepam), and desmethyl-3-hydroxydiazepam

(oxazepam), the hydroxylated derivatives being marketed as drugs in their own right. Diazepam itself is a metabolite of another benzodiazepine, medazepam.

After chronic administration of diazepam, i.e. at steady state, plasma concentrations of desmethyldiazepam (the major metabolite in blood) are similar to those of diazepam. The hydroxylated metabolites of the benzodiazepines, together with benzodiazepines which have an hydroxyl group at the C₃ position (e.g. lorazepam), are conjugated with glucuronic acid and it is these derivatives which account for the major fraction of the dose excreted in the urine.

AMPHETAMINES

Amphetamines can be metabolised by (1) oxidative deamination followed by oxidation or reduction of the ketone and conjugation of the resulting acid and alcohol products; (2) *N*-oxidation; (3) hydroxylation of the aromatic ring and of the alkyl side-chain at the β-position; and (4) *N*-dealkylation.

Amphetamine is converted by oxidative deamination to phenylacetone which is further oxidised to benzoic acid; this latter product is excreted as its glycine conjugate, hippuric acid.

Although reduction of ketones is possible, it does not seem to be a very important route of metabolism in man. Oxidative deamination (following *N*-dealkylation where appropriate) appears to be the major pathway for those drugs which are extensively

metabolised. *N*-Oxidation of amphetamines gives rise to hydroxylamines and nitro derivatives, but these products are rarely excreted in the urine in large quantities; hydroxylamines are generally excreted as conjugates or as free and conjugated oximes after further rearrangement of the molecule. Aromatic hydroxylation to yield phenolic derivatives varies with different amphetamines. For some (e.g. methylamphetamine) it is a relatively important route of metabolism (accounting for up to 15% of the dose excreted) whereas for others (e.g. fenfluramine and amphetamine) it is insignificant. β-Hydroxylation of the alkyl side-chain accounts for only a relatively small proportion of the total metabolism of most amphetamines; less than 5% of amphetamine is excreted as norephedrine (phenylpropanolamine). The extent of *N*-dealkylation of phenethylamine drugs may be important in the interpretation of

analytical findings since a number of drugs (methamphetamine and prenylamine for example) are metabolised to amphetamine. Obviously, if only the amphetamine metabolite is detected then results might be misinterpreted.

TRICYCLIC ANTIDEPRESSANTS

Metabolism of the tricyclic antidepressant drugs occurs by three major pathways: *N*-oxidation, hydroxylation of the alicyclic ring at C₁₀ and of the aromatic ring at C₂, and *N*-dealkylation of the dialkylamino group. The latter route gives rise to the most important metabolites since the *N*-demethylated metabolites are themselves psychoactive. Amitriptyline is metabolised to nortriptyline, and imipramine to desipramine, both metabolites being used clinically as drugs in their own right. When monitoring concentrations of tricyclic antidepressants for their therapeutic effect, it is essential to determine both the parent drug and the

amitriptyline

imipramine

desalkyl metabolites as the latter may be present in a significant quantity. In spite of the widespread use of tricyclic antidepressants, the contribution of the metabolites to the total therapeutic effect has not been quantified and concentrations of the parent drug and its metabolites are usually summed to provide an estimate of therapeutic activity. The pharmacology of 10-hydroxy metabolites, which also make up a large proportion of the total drug and metabolite concentration, is under investigation and they may be found to play a major role in the total clinical effect. The hydroxy metabolites predominate in the urine, usually occurring as glucuronide conjugates.

Metabolism of tricyclic drugs by aromatic hydroxylation and *N*-oxidation is of minor importance.

PHENOTHIAZINES

The phenothiazines have the general formula

They provide examples of drugs which undergo sulfoxidation to yield sulfoxides and sulphones. In addition, *N*-oxidation (at the N¹⁰-position), hydroxylation of one or both of the aromatic rings, *N*-dealkylation of the N¹⁰-side-chain, and fission of the N¹⁰-side-chain may also occur. The phenolic metabolites are then conjugated with glucuronic acid or sulphate; the metabolites are excreted in both the urine and the bile.

The number of different metabolic routes which are possible results in a complex mixture of metabolites for many phenothiazines. For example, many of the drugs which contain an *NN*-dimethyl-aminoalkyl side-chain (e.g. chlorpromazine) are extensively metabolised by *N*-oxidation, together with hydroxylation, sulfoxidation, and *N*-dealkylation.

OPIATES

The opiates are metabolised by a wide variety of pathways even within a single compound. These include hydrolysis followed by conjugation, *O*-dealkylation, as well as the more common *N*-

Chlorpromazine – Major Metabolic Routes

dealkylation. Thus diamorphine (heroin) is rapidly hydrolysed in the body to 6-monoacetylmorphine, which is further and more slowly hydrolysed to morphine. The morphine so formed is excreted

largely as the 3-glucuronide together with some free morphine.

Morphine may also be metabolised by *N*-demethylation to normorphine. Alkylation to produce codeine (the 3-*O*-methyl derivative) has also been suggested but more recent work indicates that codeine arises due to the presence of codeine or acetylcodeine as contaminants in morphine or illicit diamorphine preparations. Codeine can be metabolised by the reverse reaction, *O*-demethylation, to yield morphine, as well as by conjugation with glucuronic acid and *N*-demethylation.

Reduction Reactions

Aldehydes and ketones undergo reduction to primary and secondary alcohols (e.g. chloral is converted to trichloroethanol and prednisone is reduced to prednisolone).

Nitro and azo compounds are reduced to amines (e.g. nitrofurantoin is reduced to its amino derivative and sulphasalazine is reduced to sulphapyridine).

Another example is the reduction of disulphides to thiols (e.g. disulfiram is converted to diethyldithiocarbamic acid).

Hydrolysis

Hydrolysis is an important route of metabolism for esters, amides, carbamates, and acyl hydrazines. Aspirin is rapidly converted to salicylic acid; this may be further metabolised to gentisic acid (5-hydroxysalicylic acid), conjugated with glucuronic acid or glycine, or excreted unchanged.

Procaine is hydrolysed by plasma esterases to 4-aminobenzoic acid and diethylaminoethanol.

Hydrolysis of isoniazid gives isonicotinic acid which is further metabolised to its glycine conjugate.

The major pathway for chlordiazepoxide metabolism involves hydrolysis of the 2-methylamino substituent to yield the lactam derivative, demoxepam. This is excreted in the urine unchanged or undergoes further cleavage to the corresponding acid before excretion

Conjugation Reactions

Oxidation, reduction, and hydrolysis usually produce metabolites which have a reactive functional group. Several of the more common conjugation reactions which mask these functional groups have been mentioned above and are now described in more detail.

GLUCURONIDE FORMATION

Glucuronic acid can be conjugated with a wide variety of functional groups to form either an ester (as with carboxylic acids such as phenylacetic acid), or an ether (as with phenolic or alcoholic groups, e.g. morphine or trichloroethanol). *O*-Glucuronides may be formed with primary, secondary, and tertiary alcohols. Analogous *N*- and *S*-glucuronides may also be produced (e.g. meprobamate and diethyldithiocarbamic acid), and a C—C linked glucuronide is formed with phenylbutazone.

Although the different glucuronides all facilitate drug elimination either by the kidney or the liver, they differ quite markedly in their stability. Thus,

N-glucuronides of aromatic amines and sulphonamides tend to be unstable while, at the other extreme, ether glucuronides require hot concentrated acid to effect hydrolysis of the conjugate. It has been suggested that artefactual *N*-glucuronides of some drugs may be produced in urine on long standing.

SULPHATE FORMATION

Sulphate conjugates are formed with hydroxy compounds (e.g. alcohols and phenols) or aromatic amines. For example, morphine-3-*O*-ethereal sulphate is a minor metabolite of morphine and *N*-phenylsulphamic acid is a metabolite of aniline. Sulphate conjugates are strong acids and are readily excreted in the urine; they are of relatively little importance in drug metabolism.

ACETYLATION

Acetylation by *N*-acetyltransferase occurs frequently with primary and secondary amines (e.g. sulphadiazine) and substituted hydrazines (e.g. isoniazid and hydralazine); the *N*-monoacetyl derivatives are usually produced.

METHYLATION

Methylation is a common feature of the metabolism of phenols and *N*-heterocyclic compounds. Thus, phenolic steroids, adrenaline, and some other catecholamines undergo *O*-methylation, while pyridine, nicotinic acid, and normorphine undergo *N*-methylation. The reaction occurs under the influence of 5-adenosylmethionine and a non-specific methyl transferase.

CONJUGATION WITH AMINO ACIDS

Following the activation of drugs and metabolites by acetyl-coenzyme A, conjugation with glutamine (in particular of arylacetic acids such as phenylacetic acid) and glycine (of carboxylic and aromatic acids such as salicylic acid) is common. Glutamine conjugation occurs less frequently than conjugation with glycine.

CONJUGATION WITH GLUTATHIONE

Reactive electrophiles produced by oxidative reactions conjugate with the tripeptide glutathione (glutamylcysteinylglycine) with the aid of a series of glutathione-5-transferases. Paracetamol, which is largely excreted as ethereal sulphate and glucu-

ronide conjugates, also undergoes metabolism to an active intermediate which is then conjugated with glutathione. This conjugate is rapidly hydrolysed and excreted in the urine as the mercapturic acid (*N*-acetylcysteine) derivative.

DRUG METABOLISM AND TOXICITY

Toxic metabolites can occur in the same way that pharmacologically active and/or inactive metabolites are produced. For example, deacetylation of phenacetin yields *p*-phenetidine, the precursor of substances believed to be responsible for methaemoglobinemia.

Similarly, paraoxon, the oxygenated metabolite of parathion, is responsible for the severe toxicity observed after the ingestion of parathion.

Changes in the pathways of metabolism of a drug can also result in toxicity. In paracetamol intoxication, the pathways responsible for sulphate and glucuronide conjugation become saturated and the concentrations of cysteine and mercapturic acid metabolites increase. When the production of the two latter metabolites increases sufficiently to deplete stores of glutathione, the active intermediate can no longer be conjugated and is thought to bind irreversibly to cellular macromolecules such as DNA, RNA, and proteins, resulting in a dose-related hepatic necrosis. Initial theories suggested that an epoxide metabolite was responsible for the tissue damage, but this metabolite has not been isolated. It is now believed that the toxic molecule arises from the oxidation of paracetamol to acetyl-imino-*p*-benzoquinone.

Whatever the actual pathway, the administration of compounds containing sulphhydryl groups has been shown to be effective in paracetamol intoxication, presumably because they are able to bind to the electrophilic species in the same way as glutathione. Another example of drug toxicity related to the extent and nature of metabolism is that associated

with acetylation. The rate of acetylation is controlled by an *N*-acetyltransferase which shows genetic polymorphism; about 60% of Caucasians are classified as 'slow' acetylators. The extent of acetylation is related to the toxic effects of certain drugs. For example, the *N*-hydroxy metabolite of acetylated isoniazid is thought to cause isoniazid-related hepatotoxicity. This toxicity is more severe in 'rapid' acetylators than in 'slow' acetylators but, as with paracetamol, some protection can be given by sulphydryl compounds.

In contrast, 'slow' acetylators appear to show a greater incidence of systemic lupus erythematosus following administration of hydrazine drugs than do 'rapid' acetylators as this toxic reaction is related to the parent drug.

Drug Concentration and Pharmacological Response

For most drugs there is a correlation between the dose given, the concentration of the drug in blood, and the duration and intensity of the biological effect. In general, as blood concentrations rise above those associated with a therapeutic effect, the frequency and severity of toxic side-effects increase.

The relationship between drug action and the processes of absorption, distribution, and elimination has been successfully applied in clinical pharmacology for the optimisation and individualisation of therapy. In clinical and forensic toxicology, similar relationships are applied in the interpretation of analytical results.

The significance of toxicological data is assessed by attempting to explain the clinical or toxicological effects in terms of the drug concentrations found. Before this can be done the toxicologist must be satisfied that the clinical and analytical data are valid.

VALIDITY OF TOXICOLOGICAL DATA

A number of factors affect the validity of toxicological findings and the interpretation of them. It is important to ensure that the measured concentration of the drug and any active metabolites can be related directly to the concentration at the receptor. This is obviously dependent on the sample and the sampling procedure, the distribution of drugs and metabolites in the sample, the analytical methodology, and the rational interpretation of the pharmacological response.

Samples

The choice of the sample is of paramount importance if the clinical condition is to be interpreted in terms of the analytical result. Blood and urine are the samples most commonly used for analysis, but the concentration in blood is generally considered to provide the best possible estimate of the amount of drug at the receptor site. If blood is provided, care must be taken to ensure that the sample has not been contaminated during autopsy by other fluids such as stomach washings or urine. The origin of a blood sample must be established, as blood from different parts of the body can have very different drug concentrations.

Whenever possible, it is advantageous to measure the drug concentration in two or more independent samples; the value of a result from a single sample will always be limited unless the distribution of the drug is known. Tissues which selectively take up a particular drug may have a much higher concentration than that found in blood. For example, solvents and other lipid-soluble substances are preferentially absorbed into the fatty tissues of the brain; digoxin and other cardiac glycosides are taken up by cardiac muscle; biliary concentrations of drugs which are excreted from the liver as glucuronides (e.g. morphine) may be considerably higher than their concentrations in blood.

In addition to being distributed unevenly throughout the body, a drug may not be distributed evenly within the separate parts of a single tissue. In blood, drugs may tend to be concentrated either in the plasma or in the erythrocytes. Thus, it may prove to be of little value to examine a plasma sample in a case where the drug involved is known to be concentrated in the erythrocytes (e.g. acetazolamide). It is usual to examine whole blood in forensic cases whereas plasma is usually examined in clinical situations, and there could be a significant difference in the concentrations when measured in the two situations. The whole blood concentration and the plasma concentration cannot be compared until one or the other has been corrected by reference to the plasma: whole blood ratio.

Analytical Methodology

The techniques used to extract and quantify a drug may also lead to problems in relating the measured drug concentration to the observed clinical condition. Different extraction procedures may lead to

different results, so much so that the amount of drug recovered from the sample may bear little relation to the amount actually present. Similarly, it is futile to try to interpret a drug concentration which has been measured by a technique which is not sufficiently selective to exclude all metabolites, other drugs, and endogenous materials which might interfere with the analysis. For example, radioimmunoassay (RIA) techniques are being increasingly used to screen for the presence of as many individual drugs from within a pharmacological or chemical group as is possible. Hence, drug concentrations measured by RIA are often higher than those obtained by a more specific method, e.g. phenobarbitone concentrations measured by HPLC may be only 10% of those measured by RIA. This illustrates the obvious dangers of trying to interpret drug concentrations which have been obtained using an RIA designed for screening purposes.

An accurate interpretation of analytical results requires the use of a specific immunoassay, or identification and quantification with a chromatographic technique.

Similarly, it is pointless to determine the concentration of a drug which has been identified only as a member of a large pharmacological group, especially when that group has a wide range of biological potencies (e.g. barbiturates). In such cases, the drug concentration cannot be related to the pharmacological response. For example, a blood-barbiturate concentration of 15 µg/ml may represent a therapeutic concentration of phenobarbitone, a toxic concentration of amylorbarbitone, or a fatal concentration of thiopentone.

Pharmacological Response

Even when it has been established that the measured drug concentration in the blood accurately represents the concentration of drug at the receptor site, it must also be established that the clinical response is a primary consequence of the presence of the drug. For example, drugs with an irreversible biochemical effect, such as reserpine and monoamine oxidase inhibitors, still have clinical effects long after drug administration has stopped, and when plasma concentrations of the drug are negligible. Similarly, unless the time of ingestion is known with reasonable accuracy, it is almost impossible to relate drug concentrations measured post mortem with the secondary and potentially fatal responses to substances such as paracetamol (liver damage), and paraquat (lung necrosis). Incorporation of drugs or

chemicals into endogenous metabolic cycles may result in a toxicity (lethal synthesis) which is not related to blood concentrations of the drug. Finally, interpretation is made difficult or impossible when underlying disease has altered the pharmacological action of the drug, or when a patient has died of asphyxia following inhalation of vomit.

Active Metabolites

When an active metabolite makes an important contribution to the overall pharmacological response, the interpretation of toxicological data is further complicated. Toxicological situations involving such metabolites (e.g. oxazepam, nortriptyline, desipramine, and phenobarbitone, derived from diazepam, amitriptyline, imipramine, and methylphenobarbitone, respectively) can be misinterpreted if only the parent drugs are assayed. The concentrations of active metabolites must be taken into account. Although there is controversy over the best way to evaluate the contribution of metabolites, the individual concentrations of drug and metabolites are often added together to provide an estimate of the total amount of active drug species present in the sample. This assumes that their relative pharmacological activities are equal, which is not generally true.

THERAPEUTIC, TOXIC, AND FATAL DRUG CONCENTRATIONS

Reliable assessments of the significance of analytical findings can be made only by comparing the results with information on drug concentrations and associated clinical responses which have been reported in other cases. Comprehensive collections of reference data which present the relationship between concentration and effect (i.e. therapeutic, toxic, and fatal concentrations) are an essential aid in determining whether or not a measured drug concentration might explain the observed response. Wherever possible, appropriate data have been included in the monographs in Part 2.

In order that a concentration-effect relationship can be more easily recognised, analytical data should be expressed in a form which allows an accurate assessment of the significance of results to be made. Concentration-response curves, which are analogous to the dose-response curves used in experimental pharmacology, can be used in clinical and forensic toxicology. Curves of this type are illustrated in Fig. 6 which shows the cumulative plots of blood-

Fig. 6. Cumulative plots of percentage of cases versus blood concentrations of phenobarbitone in therapeutic, toxic, and fatal categories (A. H. Stead and A. C. Moffat, *J. forens. Sci. Soc.*, 1982, 22, 47–56).

phenobarbitone concentrations measured in subjects showing a therapeutic, toxic, or fatal response to the drug. The curve shows that a phenobarbitone concentration of 50 µg/ml includes all of the subjects in the therapeutic category, about 75% of toxic (hospital emergency) cases, and about 50% of the fatalities. The curves present all available data in a clear and concise way and give a good indication of the likelihood of a measured drug concentration giving rise to the observed response. As well as dividing data into the three clinical categories, it may also be useful to subdivide results further by age, acute or chronic use, etc.

Concentration ranges derived from concentration-response curves can also be used to describe the relationship between concentration and effect. The blood concentration which accounts for 50% of patients within each clinical category (median effective concentration, EC50 value) can be compared with the concentrations which account for 10% (EC10 values), and 90% (EC90 values) of the patients. The range of concentrations into which most data are known to fall (EC10 to EC90) is analogous to the linear part of the classic dose-response curve used in pharmacology, the full curve being sigmoid in shape.

It is clear that visual or numerical representations of drug concentrations derived from different sources can only be compared if the clinical or toxicological responses with which they are associated are rigorously defined. For example, the description of an observed pharmacological response as 'toxic' is often totally inadequate since toxic effects can range for instance from drowsiness to severe coma.

FACTORS WHICH AFFECT PHARMACOLOGICAL RESPONSE

Similar drug concentrations will not produce the same response in all subjects. Some may respond at drug concentrations which might be considered subtherapeutic, whilst others may not respond with blood concentrations which are normally associated with toxic side-effects; concentrations found in chronic drug users or in drug abusers and addicts may be much higher than in normal subjects because of tolerance to pharmacological effects; the half-life of a drug in elderly subjects may be increased because of a decreased rate of metabolism and excretion. Differences in the capacity to eliminate drugs probably account for the major part of individual variability, but many other factors, both physiological and pharmacological, can influence drug concentrations and their associated clinical responses.

The combined effect of all of these factors is to make the task of interpreting analytical results even more difficult. Pharmacokinetic and toxicological data, such as that given in the monographs in Part 2, must be used circumspectly when a specific case is being examined because there is always the possibility of misinterpretation if consideration is not given to the special circumstances of the case.

Physiological Factors

AGE

Young children and elderly people generally have a lower metabolic capacity compared with subjects between these extremes of age. The enhanced sensitivity of the very young to drugs can be accounted for by the fact that the microsomal enzymes which are responsible for metabolism (especially conjugation with glucuronic acid) are not fully active until several months after birth. Further, very young children do not have the necessary plasma-binding proteins which help to compartmentalise drugs. Older children (over 5 years old) usually metabolise drugs at similar rates and by similar routes to adults, but they require lower doses to produce comparable effects because the drugs are distributed into a smaller volume.

In elderly subjects (over 60 years old) there appears to be a decreasing capacity for drug metabolism as a consequence of a gradual decline in overall physiological efficiency. In addition, the amount of protein binding may decrease and the renal excretion may be reduced. The resulting higher blood-drug concentrations per dose (Fig. 7), and increased

drug: metabolite concentration ratios (Fig. 8), together with a wider range of therapeutic drug concentrations usually found in the elderly, will obviously complicate the interpretation of data. A further complication is that subjects tend to show an increased susceptibility and/or reduced tolerance to drug action with increasing age.

Fig. 7. Cumulative plots of the percentage of cases versus blood concentrations of amitriptyline (normalised to a dose of 100 mg) associated with different age groups.

Fig. 8. Variation of blood drug:metabolite concentration ratios with increasing age.

DISEASE

Diseases can affect all the processes by which a drug is absorbed, distributed, and eliminated from the body. A drug may be poorly absorbed during gastrointestinal disturbance; the rate of uptake of drugs which rapidly cross tissue membranes may be altered in cardiovascular diseases which alter peripheral blood flow; endogenous free fatty acids which are released into the plasma during trauma can displace drugs which are weak acids from albumin binding sites.

Diseases which affect the liver or kidneys probably have the greatest effect on drug concentrations

because normal functioning of these organs is essential for efficient metabolism and excretion. If liver function is impaired, either because of disease or necrosis associated with chronic drug use or severe drug intoxication, the bioavailabilities of drugs can increase dramatically. In addition, disease states which lower plasma protein concentrations are believed to increase free concentrations of highly bound drugs and subsequently lead to an increase in the frequency of adverse effects associated with such drugs. However, this is seldom a problem in long-term therapy as it is the unbound drug which is eliminated.

Renal disease leads to a decreased ability to excrete drugs and/or their metabolites. A drug will accumulate in plasma or tissues if the interval between doses is such that not all of the previously administered drug is removed before the next dose. Even for those drugs where excretion into the urine does not normally appear to be an important route of elimination, there can be a risk of increased toxicity during disease if significant drug accumulation takes place. This is especially true where potentially serious interactions can occur with the accumulated drug or metabolite. For example, metabolites can displace their parent drugs from binding sites on plasma and tissue proteins if their concentrations build up sufficiently.

WEIGHT

The weight of an individual obviously affects concentrations of drug in the blood as it determines the volume into which the drug is distributed. Absolute body size may account for some of the variations in drug handling which are observed between males and females, although differences in the ratio of fat: body water (greater in females), or in the rate of drug metabolism (higher in males) probably have a greater influence. However, such differences are usually small and probably have little forensic significance.

GENETIC FACTORS

The genetic control of the number of receptor sites, and genetic variations in the extent of protein binding or the rate and extent of drug metabolism, can make a marked contribution to variations in drug concentrations and responses. Polymorphic drug metabolism, caused by either missing enzymes or enzymes with reduced activity, can result in high

drug concentrations and, particularly for drugs with a low therapeutic index, abnormal clinical responses. Drugs which undergo *p*-hydroxylation (debrisoquine), acetylation (isoniazid), and oxidative dealkylation (phenacetin), provide good examples of polymorphic metabolism. Inefficient drug metabolism can lead to increased bioavailability, accumulation of the drug, and therefore to increased toxicity. For example, with some hydrazine mono-amine-oxidase inhibitors, the incidence of side-effects and toxicity is increased in slow acetylators. The inability to oxidise tolbutamide has been related to an increased incidence of cardiovascular toxicity with the drug.

Pharmacological Factors

ROUTE OF ADMINISTRATION

The route of drug administration, together with the nature of the dosage form, determines the rate and extent of absorption. Administration by inhalation or intravenous injection leads to relatively high but transient blood concentrations, whilst administration orally or by intramuscular injection produces lower concentrations of longer duration.

If proprietary preparations are given by the recommended route it may be possible to make predictions of the dose from blood concentrations because comparable data are usually available. However, when illicit drugs or preparations are involved, prediction is much more difficult. Volatile solvents which are encountered in glue-sniffing are inhaled under a wide variety of conditions; variable amounts of cannabinoids are absorbed from the lung during smoking of cannabis; there may be considerable variations in the amount of lysergide administered by mouth from paper tabs impregnated with a solution of the drug.

The majority of overdoses and poisonings encountered by the toxicologist involve drugs which have been administered orally. Compared with administration of drugs given by intravenous injection, where absorption can be considered as total and almost instantaneous, administration by mouth often leads to reduced and variable bioavailability. This can be attributed to a number of factors: drugs may be unstable in the acidic conditions of the stomach or in the alkaline conditions of the small intestine; they may be metabolised by bacteria in the gastro-intestinal tract or by enzymes in the mucosal lining of the gut prior to absorption; they may become adsorbed onto the stomach contents; they may be absorbed in varying amounts if the gut motility and/or the blood flow in the gut wall are

disordered. Finally, and probably the most important, the individual's capacity to metabolise drugs during the first pass of the drug through the liver has an enormous effect on the fraction of drug absorbed and which remains for further distribution to peripheral tissues, especially if the drug is extensively metabolised by the liver.

As well as affecting the amount of a drug which gets into the blood, the route of administration also affects the rate of entry. In some respects this rate may be more important than the final blood concentration in determining the severity of the observed clinical response. Thus, a fatal drug dose given intravenously is often much smaller than a fatal dose given by mouth because the injected drug is able to reach the site of action very rapidly.

DOSE AND DURATION OF THERAPY

The concentration of a drug in the body is mainly determined by the size of the dose and the frequency of dosing. In general, the concentration following administration of multiple doses is higher than that observed after a single dose. If a drug with a long half-life is given in multiple doses with a sufficiently small dose interval, the drug will accumulate in the body, and this may lead to progressively serious toxicity. This is a particular problem with some tranquillisers and hypnotics which are slowly eliminated and it may result in unwanted daytime sedation and impaired performance.

Clinical and forensic toxicologists are involved most often with drugs which have been taken in large single doses rather than with drugs which have been administered regularly in small doses over a long period. In the normal dosage range, the rates of absorption, distribution, metabolism, and excretion of most drugs are generally considered to be proportional to the dose or concentration of the drug in blood (i.e. the processes are first-order). However, a very large dose of some drugs (e.g. barbiturates, glutethimide, and related hypnotics) can reduce gastric motility with the consequence that absorption is prolonged over several days. Overdose with slow-release preparations presents similar problems. If the dose or concentration reaches a sufficiently high level, the processes involved in drug clearance may become saturated and reduced to zero-order functions. High drug doses, therefore, have pharmacokinetic consequences as well as the more obvious pharmacological results, and the assumption of first-order kinetic behaviour may not be appropriate in cases of overdose (Fig. 9). As the eliminating systems become saturated, the half-life

Fig. 9. Semilogarithmic plots of plasma concentrations versus time for 3 doses of salicylate administered to the same subject, illustrating capacity-limited elimination. At low plasma concentrations, parallel straight lines are obtained from which the first-order elimination rate constant can be estimated. As long as concentrations remain sufficiently high to saturate the process, elimination follows zero-order kinetics (C. A. M. van Ginneken *et al.*, *J. Pharmacokinet. Biopharm.*, 1974, 2, 395–415).

of the drug will increase. In addition, the relationship between dose and blood concentrations may become non-linear, with drug concentrations increasing disproportionately more rapidly than the increase in dose.

Several drugs, including salicylate (in overdose), alcohol, and possibly some hydrazines and other drugs which are metabolised by acetylation, have saturable elimination kinetics, but the only significant clinical example is phenytoin. With this drug, capacity-limited elimination is complicated further by its low therapeutic index. A 50% increase in the dose of phenytoin can result in a 600% increase in the steady-state blood concentration, and thus expose the patient to potential toxicity.

Capacity-limited pathways of elimination lead to plasma concentrations of drugs which can be described by a form of the Michaelis-Menten equation. In such cases, the plasma concentration at steady state is given by

$$\frac{K_m R}{V_{\max} - R}$$

where V_{\max} is the maximum rate of metabolism, K_m is a constant equal to the plasma concentration at

which the rate of metabolism is one-half the maximum, and R is the rate of metabolism.

Other pathways will continue to operate but, for plasma concentrations of the order of K_m , an apparently linear decrease in concentration with time will be seen. Thus, for alcohol in healthy adult males, K_m has an average value of 82 µg/ml, and V_{\max} an average value of 202 µg/ml/hour. About 90% of alcohol elimination is usually by the capacity-limited alcohol dehydrogenase (oxidative) pathway, the remainder being by the kidneys and other routes of excretion. The renal clearance of alcohol depends on urine flow, and is approximately equal to urine flow rate, i.e. about 1 ml/min; only a trace is eliminated via the lungs. For blood-alcohol concentrations of 100, 350, 1000, and 3500 µg/ml, the elimination of alcohol will be as shown in Table 3. As the concentration rises, so the elimination rate increases (but not proportionately) to reach a value of approximately V_{\max} .

The contribution of the kidneys to elimination is negligible at low concentrations, but is about 5% of the total at 3500 µg/ml.

Table 3. Elimination of alcohol from blood at various concentrations

Concentration of alcohol in blood µg/ml	Total elimination from blood µg/ml/h	Excretion of unchanged alcohol in urine µg/ml/h	% total
100	111	0.3	0.25
350	165	1.0	0.6
1000*	195	3.0	1.5
3500*	207	10.0	4.8

*The concentration–time curve will appear linear at these concentrations, but it is only at the higher concentration that the enzyme-mediated pathway is truly zero-order.

When repeated doses of a drug are given, tolerance to the drug may arise if it affects its own disposition or response. Enzyme activities can be enhanced, which leads to an increased capacity for metabolism (e.g. patients on chronic therapy with barbiturates metabolise the drugs more rapidly than patients who have not previously taken the drugs). Alternatively, the receptor sensitivity may be modified so that the effect of a particular concentration of a drug is reduced after chronic use (e.g. the sedative effects of benzodiazepines).

Increasing tolerance results in a progressively decreasing drug effect, and the need for an increased dose; habituation and addiction may be the final clinical outcome. Thus, addicts can tolerate doses of morphine which might be considered toxic or even fatal in non-addicts. Similarly, rapidly devel-

oping tolerance to the sedative effects of phenobarbitone is a common feature of prolonged therapy with the drug. Epileptic patients treated with phenobarbitone are often free from any adverse effects despite having blood-drug concentrations normally associated with serious toxicity in patients not accustomed to taking the drug.

Tolerance invariably extends the upper limit of the therapeutic range of drugs, and there is a more marked overlap between concentrations associated with different clinical responses. When tolerance is suspected, some of the problems of interpreting data can best be resolved by reference to previous results from the same patient (e.g. results of a therapeutic drug monitoring programme). Unfortunately, in most forensic cases such background information is not available and in these instances blood concentrations alone are of little value. A more reliable interpretation of analytical data can only be made by comparison of blood concentrations with those measured in urine, bile, or liver (where concentrations can be much higher in addicts), and/or by measuring the relative amounts of unchanged drug and its metabolite(s).

PROTEIN BINDING AND DISTRIBUTION IN BLOOD

After absorption, a drug is distributed non-uniformly around the body, including binding to plasma proteins, distribution between plasma and erythrocytes, and binding to peripheral tissues. The extent of this binding and distribution in the blood has a considerable influence on the blood concentration, and on the intensity and duration of its pharmacological effect, because only the free (unbound) drug can be cleared from the body by metabolism and excretion. Furthermore, only the free fraction can diffuse across biological membranes and equilibrate with the receptor site.

It has been proposed that measurement of the concentration of free drug in the plasma (i.e. that fraction of the drug which is available to cause a response) may be more relevant than measurement of the concentration of total drug (i.e. free plus bound) in whole blood or plasma. However, this is not always practicable, and neither clinical nor forensic toxicologists do so routinely. It is generally assumed that the total concentration of drug in the blood is proportional to its free concentration. This may be true for low concentrations of drugs, or for drugs whose binding is not capacity-limited. However, for those drugs whose binding to plasma proteins is saturable, free concentrations will increase proportionately more rapidly than increases in total

concentrations, for any given increase in dose. For example, the free concentration of a drug which is 90% bound at the point of saturation of the protein binding will be 10% of the total drug concentration. If the total concentration is doubled, no more drug will be bound to proteins, and the free concentration will increase by a factor of 11 to over 50% of the total concentration. The extent of the binding of a drug to plasma proteins, and also its distribution between plasma and erythrocytes, are important factors in establishing the concentration-effect relationship in an individual.

Some drugs are only poorly protein-bound (e.g. codeine, digoxin, meprobamate, paracetamol), whilst others are highly bound (e.g. amitriptyline, chlorpromazine, medazepam), although the percentage of bound drug can vary between individuals. Similarly, some drugs are only poorly taken up by erythrocytes (e.g. digitoxin, promethazine, warfarin), whilst uptake can be extensive for others (e.g. acetazolamide, chlorthalidone).

Information about the extent of protein binding, and about the plasma: whole blood ratio provides an invaluable guide to the interpretation of drug concentrations in unfractionated blood samples. Using such data, total blood concentrations can be related to the unbound drug concentrations which are responsible for the observed condition. These data have been included, wherever possible, in the monographs in Part 2.

The degree of binding or of distribution of a drug in the blood is influenced by a number of factors of which disease, dose, and competition for binding sites between two drugs are the most important. The low concentrations of plasma proteins associated with some disease states can lead to the saturation of binding sites even with therapeutic doses. Similarly, if the concentration of plasma proteins is normal, binding sites can become saturated if sufficiently large doses are given, as with an overdose. This is especially true of most weakly acidic drugs which are almost completely ionised at the pH of plasma and therefore have a high affinity for albumin.

In general, the competition for binding sites between two drugs is only of toxicological significance if the displaced drug is normally extensively bound (i.e. more than 75%), and if its volume of distribution is low (i.e. less than about 0.07 litres/kg), so that a small percentage change in binding has a relatively large effect on free drug concentrations in blood. For example, if warfarin and phenylbutazone are

administered simultaneously, competition for the same binding sites (on albumin) can increase the concentration of unbound warfarin (which has the lower affinity for protein) resulting in enhanced anticoagulant activity.

Thus, any disturbance of the binding of a drug, or of its distribution in the blood, changes its pharmacokinetic characteristics. These changes are predominantly associated with the apparent volume of distribution and the half-life of the drug, both of which decrease with decreased binding. Consequently, as the free drug fraction increases, so its total clearance also increases. However, the intrinsic clearance (the maximum attainable clearance of the unbound drug) remains constant as it is only a measure of the drug-eliminating capacity of a particular organ. When it is suspected that there has been some change in the binding of a drug or in its distribution in the blood, and especially for drugs which are highly bound or are concentrated in the erythrocytes, literature values for volume of distribution and half-life must be used with caution.

DRUG INTERACTIONS

In the majority of cases in clinical and forensic toxicology, there is more than one drug involved. Multi-drug therapy and abuse is prevalent and this, together with the added problems of self-medication with over-the-counter drugs and the widespread use of alcohol, makes interpretation of data even more complicated. The pharmacokinetic and other data in the monographs in Part 2 refer to drug concentrations and responses observed following the administration of the drug alone. In practice, when comparing these data with analytical results involving several drugs, it must be remembered that the clinical response is often a consequence of the combined actions of more than one drug. If the significance of the results is to be assessed correctly, it is essential to consider the quantitative effects of any interactions which might occur between drugs taken in combination.

Drug interactions can be divided into two types: those which affect the drug concentration (i.e. which alter the processes of absorption, distribution, and elimination) and those which affect the response (by changing its duration and severity). The consequences of most drug combinations can be predicted relatively accurately with a knowledge of their pharmacology and pharmacokinetics.

Drugs with opposite pharmacological activities (e.g.

barbiturates and amphetamines) may have an antagonistic effect. Conversely, the additive effects or side-effects of two drugs with the same pharmacological action (e.g. central nervous system depressants) may prove fatal even though the individual drug concentrations are not toxic themselves. Further, a drug with a high affinity for tissue proteins might displace a second drug from binding sites, while a drug which changes urinary pH or which competes for the same active transport system in the proximal tubules of the kidney might inhibit renal excretion. Other important mechanisms for drug interactions include: interference with absorption of other drugs; modification of rates and routes of metabolism; and changing the accessibility of receptors and tissue sites.

Unfortunately, although a number of excellent texts discuss the mechanisms of drug interactions and their pharmacological implications in detail, very little is understood about their quantitative effects. In most cases, these effects can only be ascertained by an examination of previous findings where the

Fig. 10. Combined blood alcohol-barbiturate concentration curves in reported cases of fatal quinalbarbitone poisoning. The various lines connect those concentration pairs which would account for the percentage of cases shown (A. H. Stead and A. C. Moffat, *Human Toxicol.*, 1983, 2, 5-14).

same combination of drugs has been used. Combined drug-drug concentration curves which connect those pairs of drug concentrations which are equally effective in causing a defined clinical condition (e.g. driving impairment, death, etc.) offer the most effective way of quantifying drug interactions. For example, the likelihood of a fatality occurring with any given combination of alcohol and quinalbarbitone can be estimated relatively easily from curves such as those shown in Fig. 10. This shows that, for instance, an alcohol concentration of 1500 µg/ml (alone accounting for 2 to 3% of fatalities) when combined with a quinalbarbitone concentration of 10 µg/ml (alone accounting for 35% of fatalities) will account for more than 75% of fatalities, where both alcohol and barbiturate were found together in such concentrations.

The Interpretation of Analytical Results

The qualitative or semi-quantitative analysis of a biological sample provides the clinical pharmacologist and the forensic toxicologist with evidence of drug intake. Such analyses may be used, for example, to confirm that a patient has or has not been complying with a therapeutic regimen, or to indicate that a controlled drug is being abused. Further, the detection of metabolites in a biological sample can show that a drug has been absorbed into the body and then eliminated (either wholly or partly) from it. Such evidence might be used to refute an allegation that a sample had been tampered with, or contaminated, after it had been taken. Quantitative analysis, on the other hand, is essential if the toxicologist is to show that sufficient drug has been administered to account for the observed clinical or toxicological condition of the patient. In addition, where several drugs have common metabolic pathways, quantification of the parent compound and any major metabolite(s) can show which drug was taken. Finally, the drug and metabolite concentrations, together with the pharmacokinetic parameters of the drug, might be used to estimate when and how much of a drug was administered, and by which route it was taken.'

IDENTIFYING THE DRUG

In most cases, qualitative analysis is sufficient to show that a particular drug has been administered. However, problems arise when a drug is rapidly and extensively metabolised so that there is none,

or very little, of the parent compound in the sample. An example of this is the difficulty of distinguishing between the use of benzphetamine alone, methylamphetamine alone, and amphetamine and methylamphetamine together, by the analysis of urine. Benzphetamine is extensively metabolised to methylamphetamine which is itself converted to amphetamine. Unless subject to chronic abuse, benzphetamine is not detected in urine following oral ingestion.

Another example involves codeine, diamorphine, and morphine. After a single therapeutic dose of codeine, the morphine concentration in urine represents about 10% of the codeine concentration for 2 to 8 hours after dosing; 24 to 30 hours after dosing, only morphine (largely as the glucuronide) is readily detectable in urine. Diamorphine is also converted to morphine in the body. The situation is further complicated by the fact that codeine is often found in the urine of persons taking illicit diamorphine despite the fact that it is not a normal metabolite. This codeine is thought to be the result of deacetylation of acetylcodeine, present as an impurity in illicit diamorphine. In this case, the codeine produced represents about 10% of the administered diamorphine. Urinary concentrations of the various drugs and metabolites can be used to differentiate between consumption of crude or pure diamorphine, and illicit or pharmaceutical preparations of morphine or codeine. However, results should be interpreted with great caution, particularly if the time between dosing and collection of a urine sample is prolonged.

In most cases, urine analysis can provide valuable information on the identity of a drug, for example in screening for drugs of abuse or in emergency toxicology. However, it is quite clear that the analysis of a blood sample obtained at the same time is essential for the identification of those compounds which are not excreted by the kidneys. Drug concentrations are generally much lower in blood than in urine but, with the appropriate choice of analytical technique, it is more likely that the parent compound will be detected rather than its metabolite. In cases where the only evidence of drug intake is the presence of an inactive metabolite in the urine or bile, there is a further restraint in making a direct link between the drug and the clinical condition of the patient. If the drug has been completely metabolised, then the body probably withstood the primary action of the drug. The real cause of the pharmacological response may be a

secondary effect or it may be some other unidentified drug.

ESTIMATING THE TIME AFTER ADMINISTRATION

The time between ingestion and taking the sample, or the survival time following a fatal dose, can be estimated in a variety of ways. Simple indications include the presence of unabsorbed drug in the stomach or further down the gastro-intestinal tract. Unfortunately, such simple approaches are not always appropriate and can be unreliable. The measurement of drug and metabolite concentrations in various tissues usually provides more useful information.

When a drug has a relatively rapid rate of metabolism, the relationship between time and drug or metabolite concentrations can help to indicate whether the drug was taken recently or in the more distant past. Diamorphine is rapidly metabolised to morphine via 6-monoacetylmorphine. Following intravenous injection, neither diamorphine nor 6-monoacetylmorphine can be detected in postmortem tissues if the survival time is prolonged. Thus, even if only traces of 6-monoacetylmorphine are detected in a postmortem sample of blood, this indicates intravenous use of diamorphine in the very recent past. No matter how rapidly death occurs, diamorphine itself is never detected because of the hydrolytic action of the plasma esterases.

The blood concentration of free morphine as a metabolite of diamorphine also correlates well with the survival time, at least over 24 hours. Average blood concentrations of morphine observed in cases where death has occurred from circulatory shock and respiratory arrest less than 3 hours after administration are 3 to 10 times greater than those seen after deaths following prolonged coma (3 to 24 hours).

Cannabis provides a similar example. The detection of Δ^9 -tetrahydrocannabinol in blood indicates very recent use of the drug (within 8 hours). Further, the concentrations of 11-nor- Δ^9 -tetrahydrocannabinol-9-carboxylic acid and its glucuronide increase with time, the ratio of the acid to Δ^9 -tetrahydrocannabinol increasing to over 50 after about 3 hours.

Concentration ratios of drug: metabolite or metabolite: metabolite of the above type often provide better estimates of the time since ingestion than the individual blood concentrations, especially when the time involved is relatively long. Unless a drug is very rapidly metabolised (as is the case

with diamorphine and cannabis), only very low blood concentrations of metabolites are present a short time after a single dose. Consequently, a relatively high drug: metabolite ratio can be expected in cases of very rapid death following acute overdose.

In fatalities due to overdoses of paracetamol and dextropropoxyphene, the postmortem blood concentrations of dextropropoxyphene are generally high compared with those of the major metabolite, norpropoxyphene, the dextropropoxyphene: norpropoxyphene ratio being greater than 5. This indicates that death is relatively rapid (less than 1 hour). Dextropropoxyphene is assumed to be the cause of death if total blood concentrations of drug and metabolite are in excess of 2 $\mu\text{g/ml}$. As survival time is increased, the drug: metabolite concentration ratio decreases. Thus, when an individual survives the initial phase of acute respiratory depression associated with dextropropoxyphene, the drug: metabolite ratio falls dramatically to about 0.33 at 6 hours, and to 0.1 at 12 to 24 hours. The majority of examples mentioned above, deal with fatal cases and with the estimation of survival time. In non-fatal cases, it can be no less important to differentiate between recent drug use (up to 24 hours) and use in the distant past. When metabolism is extensive, and when drug and/or metabolite concentrations in the blood are very low, it can be profitable to compare the urinary concentration of one metabolite with another. For example, diazepam is metabolised either by *N*-demethylation to desmethyldiazepam which then undergoes 3-hydroxylation to yield oxazepam, or by hydroxylation to temazepam (*N*-methyloxazepam) which is then demethylated to oxazepam. All the urinary metabolites appear as their glucuronides. After administration of a single oral dose of diazepam, the concentration of desmethyldiazepam in the urine reaches a maximum 6 to 12 hours after ingestion, the temazepam concentration reaches its maximum after 12 to 24 hours, and the oxazepam concentration reaches a maximum after 1 to 3 days. From the second day, oxazepam is the major urinary metabolite. Up to 24 hours after ingestion, the oxazepam: desmethyldiazepam concentration ratio is 1 or less, with a corresponding oxazepam: temazepam ratio of less than 0.7. Beyond 24 hours, the ratios cover a wider range of times, and estimates of the time since ingestion can only be made by comparing metabolite: metabolite ratios with absolute metabolite concentrations.

As well as relating drug and metabolite concentrations in the same biological sample, the concentration of the drug in one tissue can be related to a concentration in another. For example, if a fatality occurs shortly after the oral ingestion of a drug, then the liver: blood concentration ratio is higher than if death had occurred after a more prolonged period. Relatively high urine: blood or bile: blood concentration ratios in association with low total drug concentrations indicate that the time since drug administration is relatively long.

If a reasonable estimate of the dose is available, pharmacokinetic data can be used to estimate the survival time or the time (t) since drug administration

$$t = \frac{1}{k_{el}} \ln \left[\frac{D}{V_d c} \right]$$

This equation is for an intravenous dose. For drugs given by mouth, the equation must be modified as shown previously for estimating the dose from the time and k_{el} , and would need knowledge of the absorption rate constant (k_a), and the bioavailability (F).

$$t = \frac{1}{k_{el}} \ln \left[\frac{DFk_a}{V_d c(k_a - k_{el})} \right]$$

If two or more drugs are administered at the same time in a single pharmaceutical preparation, pharmacokinetic data can be applied to estimate the time since ingestion, even in those cases where an estimate of the dose is not available. In such situations, the determination of the relative concentrations of each drug allows the solution of simultaneous equations for concentration versus time. This approach has been used to estimate the survival time following ingestion of an overdose of a mixture of amylobarbitone and quinalbarbitone. The measurement of barbiturate concentrations in body tissues indicated an average ratio of amylobarbitone to quinalbarbitone of 1.02. Using a value of 29 hours for the half-life of amylobarbitone and 26.5 hours for the half-life of quinalbarbitone, and knowing that the preparation contained equal amounts of the two barbiturates, it was possible to estimate that death had taken place 6 to 10 hours after ingestion.

ESTIMATING THE DOSE

Estimates of how much of a drug has been taken are necessary to indicate whether an overdose has

been taken and whether it was accidental or suicidal. Measurement of a blood concentration may not always allow the differentiation of multiple therapeutic doses from large accidental or suicidal doses. Thus, thioridazine concentrations after the administration of multiple doses may show a marked overlap with those seen in fatal poisonings. However, fatal drug concentrations in the liver are at least 21/2 times greater than those seen after chronic therapy. Hence, measurement of liver concentrations as well as blood concentrations may help to evaluate the toxicological situation.

In the same way that drug and metabolite concentrations can be linked to time, they can also be related to dose regimens. Thus, steady-state drug: metabolite concentration ratios are sometimes used to check drug compliance. Also, since the extent of drug metabolism tends to decrease with increasing dose, the ratio of unchanged drug to metabolite will increase with increasing dose. Examination of the relative concentrations of parent drug and its major metabolite(s) in blood, or in other tissues as necessary, can provide invaluable information as to the size of the dose given. Thus, an amitriptyline: nortriptyline concentration ratio of less than 2 is consistent with steady-state drug concentrations following administration of therapeutic doses, while a ratio greater than 2 is more consistent with the ingestion of larger, potentially toxic doses.

When a drug is extensively metabolised, large acute doses can result in metabolic profiles significantly different from those seen after therapeutic doses. Thus, following administration of normal single doses of phenylbutazone, the ratio of the blood concentrations of its major metabolites oxyphenbutazone and 3'-hydroxyphenylbutazone may be as high as 10:1. In overdose, the pattern of metabolism can be reversed, giving ratios as low as 1:5. Similarly, the metabolic profile of diazepam in urine changes dramatically with dose, and the ratio of desmethyldiazepam to oxazepam concentrations can provide useful information regarding the relative size of an ingested dose of the drug. When doses are low, demethylation of diazepam appears to be more important than hydroxylation, while hydroxylation becomes more important at higher doses.

Once tissue-drug concentrations or drug: metabolite concentration ratios have established that an overdose was or was not administered, the actual amount of drug ingested may be estimated. Ideally,

the dose should be determined by measuring the total amount of drug remaining in the body (including any unabsorbed drug in the gastro-intestinal tract) and adding to this the amount which has been metabolised and/or excreted. Obviously this is not always practical as it is often difficult to account for the amount of drug which has been eliminated. A compromise is usually made by estimating the minimum amount of drug ingested. This can be attempted in a number of ways.

Analytical results may be compared with previously recorded data in fatal cases for which drug doses are known. The next best method is the direct comparison of peripheral blood concentrations with clinical data, i.e. blood concentrations following the administration of therapeutic doses. Finally, drug doses can be estimated using pharmacokinetic data. The half-life of the drug ($t_{1/2}$) and a reasonable estimate of the time elapsed between administration and sampling (t), together with the blood concentration (c), allow the calculation of a theoretical drug concentration at time zero (c_0) which, for intravenous administration is

$$\ln c_0 = \ln c + \frac{0.693}{t_{1/2}} t$$

This concentration can be used to estimate the dose if the volume of distribution of the drug (V_d) is known (p. 279), or it may be compared with clinical data as described above.

This pharmacokinetic approach probably gives a better estimate of the actual dose administered since it takes some account of the amount of drug eliminated. However, the use of pharmacokinetic equations may not always be appropriate, especially if relatively accurate survival times are not available and if the kinetic characteristics of the drug following administration of large acute doses are significantly different from those observed following therapeutic doses. Some of these problems can be overcome in the clinical situation if sufficient samples are available to characterise the terminal elimination kinetics of a drug taken in overdose. For example, the area under the plasma concentration-time curve of one of the major metabolites of carbamazepine (*trans*-10,11-dihydro-10,11-dihydroxycarbamazepine) has been used to estimate the amount of parent drug absorbed. Although estimates of the amount of carbamazepine administered are not always totally accurate, the approach has much to offer the clinical and forensic toxicologist.

IDENTIFYING THE ROUTE OF ADMINISTRATION

The rate at which a drug reaches its site of action is a critical factor governing the duration and the severity of the pharmacological response. If analytical findings are to be interpreted correctly, the route by which a drug is given should therefore always be considered. In a case of criminal poisoning it may be essential to establish the route of drug administration in order to corroborate evidence.

In some cases, simple facts give a clear indication of the route. Thus, residual drug in the stomach contents or gastro-intestinal tract points to oral ingestion, a needle mark in the arm indicates intravenous injection, and high concentrations in muscle tissue point to intramuscular injection. However, in the majority of cases the situation is more complex.

When there is no direct evidence to indicate how the drug entered the body, drug: metabolite concentration ratios can be particularly helpful because rates and pathways of metabolism can vary markedly with the route of administration. Thus, drug: metabolite concentration ratios in the blood are high if a drug is given intravenously, because it is distributed widely around the systemic circulation before reaching the liver. Conversely, concentration ratios can be low where the drug is given by mouth because of immediate transport to the liver (and the major metabolic sites) following absorption from the gut. Thus, more than 90% of orally administered fluphenazine is oxidised in the liver before it even reaches the systemic circulation. If the drug is metabolised in the gut itself (e.g. isoprenaline), a large fraction of the parent compound may be lost before it can be absorbed. Isoprenaline is metabolised by *O*-methylation and by conjugation of both the parent drug and its methylated derivative with sulphate. Following oral administration (and after inhalation where much of the drug appears to be swallowed) the metabolic profile is very different from that obtained following intravenous administration. Given orally, the drug is largely transformed to its sulphate conjugate at sites at or in the gut wall; very little of the drug is methylated and the conjugate is rapidly excreted. After intravenous injection, most of the drug is eliminated as the *O*-methylated derivative, either free or conjugated with sulphate. Thus, if the urinary concentration ratio of 3-*O*-methylisoprenaline sulphate: isoprenaline is greater than 2, and/or if the isoprenaline sulphate: isoprenaline ratio is less than

about 10, it is reasonable to suppose that administration of the drug was by the intravenous route.

The route-dependent variability of drug disposition into tissues may also provide useful information relating to the route of administration. Because of the physiological processes involved, substantially smaller amounts of an intravenously administered drug are partitioned into the liver than when the same drug is given orally. If death results rapidly following a large overdose by intravenous injection, the liver-to blood-drug concentration ratio would therefore be lower than that observed had the drug been given by mouth. Thus, liver: blood ratios of 2.50 and 5.01 have been observed in pentobarbitone fatalities involving intravenous and oral administration respectively, and ratios of 1.27 and 4.21 have been found for intravenous and oral fatalities involving morphine.

Part 2: Monographs

Analytical and Toxicological Data

Ultraviolet Absorption Data

In the reproductions of ultraviolet spectra,
the following notation has been used :

—————	acid solution
.....	alkaline solution
-----	neutral solution

The A_1^1 values are divided into three categories in order to provide an indication of reliability:

The letter 'a' after a figure indicates that the value is a mean value based on several reported figures all of which lie within a range of $\pm 10\%$ of the mean.

The letter 'b' after a figure indicates that the value is a single reported value of unknown reliability.

The letter 'c' after a figure indicates that the value is a mean value based on several reported figures some of which lie outside $\pm 10\%$ of the mean.

Acebutolol*Beta-adrenoceptor Blocking Agent*

(±) - 3' - Acetyl - 4' - (2 - hydroxy - 3 - isopropylamino-propoxy)butyranilide
 $C_{18}H_{28}N_2O_4 = 336.4$
 CAS—37517-30-9

Crystals. M.p. 119° to 123°.

Acebutolol Hydrochloride

Proprietary Names. Neptall; Prent; Sectral. It is an ingredient of Secadrex.

$C_{18}H_{28}N_2O_4 \cdot HCl = 372.9$

CAS—34381-68-5

A white or slightly cream-coloured powder. M.p. 141° to 144°.

Dissociation Constant. pK_a 9.4.

Colour Tests. Methanolic Potassium Hydroxide—yellow; Nessler's Reagent—orange (slow); Sulphuric Acid—yellow.

Thin-layer Chromatography. *System TA*—Rf 47; *system TB*—Rf 00; *system TC*—Rf 03.

Gas Chromatography. *System GA*—RI 2440 and 2775.

High Pressure Liquid Chromatography. *System HA*— k' 1.4.

Ultraviolet Spectrum. Aqueous acid—234 nm ($A_1^1 = 655$ b), 320 nm ($A_1^1 = 75$ b); methanol—235 nm ($A_1^1 = 866$ a), 328 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1665, 1245, 1525, 1495, 1217, 1285 (acebutolol hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 72, 43, 30, 56, 151, 221, 41, 98.

Quantification. **HIGH PRESSURE LIQUID CHROMATOGRAPHY.** In plasma or urine: acebutolol and metabolites, sensitivity 20 ng/ml in plasma, UV detection—J. N. Buskin *et al.*, *J. Chromat.*, 1982, 230; *Biomed. Appl.*, 19, 438–442.

RADIOIMMUNOASSAY. In plasma: detection limit 10 pg—B. Gourmel *et al.*, *Clinica chim. Acta*, 1980, 108, 229–237. In plasma: diacetalol—B. Gourmel *et al.*, *Clinica chim. Acta*, 1981, 115, 229–234.

Disposition in the Body. Absorbed after oral administration; bioavailability about 40%. The major metabolite is the acetyl derivative, diacetalol, which is active. After an oral dose, about 20 to 40% of the dose is excreted in the urine in 24 hours, about 9 to 12% of the dose as unchanged drug and about 12 to 24% as diacetalol. Up to about 60% of the dose is eliminated in the faeces as unchanged drug and diacetalol. After an intravenous dose, relatively more is excreted in the urine than in the faeces, and the proportion of unchanged drug in the urine is greater than after an oral dose.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 400 mg, administered to 8 subjects, a mean peak plasma concentration of 0.7 $\mu\text{g/ml}$ was attained in 2 hours; a mean peak concentration of diacetalol of 0.8 $\mu\text{g/ml}$ was attained in 4 hours (A. A. Gulaid *et al.*, *Biopharm. Drug Disp.*, 1981, 2, 103–114).

Steady-state concentrations of 0.51 to 1.23 $\mu\text{g/ml}$ (mean 0.7) were reported during chronic oral administration of 300 mg every 6 to 8 hours to 6 subjects; the concentration of diacetalol was 0.63 to 4.43 $\mu\text{g/ml}$ (mean 2.2) (R. A. Winkle *et al.*, *Br. J. clin. Pharmacol.*, 1977, 4, 519–522).

HALF-LIFE. Plasma half-life, acebutolol about 7 to 11 hours, diacetalol about 12 hours.

VOLUME OF DISTRIBUTION. About 1 to 3 litres/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 0.8.

PROTEIN BINDING. In plasma, about 20%.

Dose. The equivalent of 0.2 to 1.2 g of acebutolol daily.

Accecaïnide*Anti-arrhythmic*

Synonym. *N*-Acetylprocainamide
 4'-[(2-Diethylaminoethyl)carbamoyl]acetanilide
 $C_{15}H_{23}N_3O_2 = 277.4$
 CAS—32795-44-1

**Accecaïnide Hydrochloride**

$C_{15}H_{23}N_3O_2 \cdot HCl = 313.8$
 CAS—34118-92-8
 Crystals. M.p. 190° to 193°.

Gas Chromatography. *System GA*—RI 2698.

Ultraviolet Spectrum. Aqueous acid or alkali—266 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1639, 1509, 1527, 1696, 1600, 1259 (accecaïnide hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 58, 99, 56, 162, 132, 149, 205.

Quantification. See also under Procainamide.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma: sensitivity 500 ng/ml—J. M. Strong *et al.*, *J. Pharmacokinet. Biopharm.*, 1975, 3, 223–235.

Disposition in the Body. Readily absorbed after oral administration; bioavailability about 85%. Up to 85% of a dose is excreted in the urine as unchanged drug in 48 hours, with only 2 to 3% excreted as procainamide and less than 1% as the monodesethyl metabolite.

Accecaïnide is the principal active metabolite of procainamide.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 10 to 30 µg/ml.

After a single oral dose of 1.5 g to 9 subjects, peak plasma concentrations of 7.4 to 17.2 µg/ml (mean 12), were attained in 1.5 to 4 hours (W. K. Lee *et al.*, *Clin. Pharmac. Ther.*, 1976, 19, 508–514).

Following oral administration of 1 g four times a day to 8 subjects, steady-state plasma concentrations of 9.3 to 25.5 µg/ml (mean 18) were reported (A. J. Atkinson *et al.*, *Clin. Pharmac. Ther.*, 1977, 21, 575–587).

TOXICITY. Toxic effects may occur at plasma concentrations within the therapeutic range.

HALF-LIFE. Plasma half-life, about 6 to 9 hours in normal subjects; increased in subjects with heart disease or renal impairment.

VOLUME OF DISTRIBUTION. About 1.5 litres/kg.

CLEARANCE. Plasma clearance, about 3 ml/min/kg.

PROTEIN BINDING. In plasma, about 10%.

NOTE. For a review of the pharmacokinetics of accecaïnide see S. J. Connolly and R. E. Kates, *Clin. Pharmacokinet.*, 1982, 7, 206–220.

Dose. Accecaïnide has been given in doses of 2 to 6 g daily.

Acephylline*Xanthine Bronchodilator*

Synonyms. Acephylline Piperazine; Piperazine Theophylline Ethanoate.

Proprietary Names. Dynaphylline; Etaphylline; Etophylate.

Piperazine bis(theophyllin-7-ylacetate)
 $(C_9H_{10}N_4O_4)_2 \cdot C_4H_{10}N_2 = 562.5$
 CAS—18833-13-1

A white crystalline powder. M.p. 260°.

Freely **soluble** in water; slightly soluble in ethanol.

Colour Test. Amalic Acid Test—orange/violet.

Thin-layer Chromatography. *System TA*—Rf 04; *system TB*—Rf 01; *system TC*—Rf 01. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1000.

Ultraviolet Spectrum. Aqueous acid—274 nm ($A_1^1 = 317$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1700, 1660, 1612, 1538, 1298, 1219 (KBr disk).

Mass Spectrum. Principal peaks at m/z 44, 194, 109, 67, 86, 238, 56, 85.

Quantification. **GAS CHROMATOGRAPHY.** In urine: FID—J. Zuidema and H. Hilbers, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 445–447.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: theophylline-7-acetic acid, sensitivity 25 ng/ml, UV detection—S. Sved *et al.*, *Biopharm. Drug Disp.*, 1981, 2, 177–184.

Disposition in the Body. Very poorly absorbed after oral administration. It is metabolised to theophylline-7-acetic acid but does not appear to be converted to theophylline.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 1 g to 2 subjects, peak plasma concentrations of 0.28 and 0.14 µg/ml of theophylline-7-acetic acid were attained in 1.5 and 2 hours, respectively (S. Sved *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, theophylline-7-acetic acid about 1 to 2 hours.

VOLUME OF DISTRIBUTION. Theophylline-7-acetic acid 0.5 litre/kg (single subject).

CLEARANCE. Plasma clearance, theophylline-7-acetic acid 7 ml/min/kg (single subject).

REFERENCE. S. Sved *et al.*, *ibid.*

Dose. 1.5 to 3 g daily.

Acepromazine

Tranquilliser

Synonym. Acetylpromazine

Proprietary Name. Plégicil

10-(3-Dimethylaminopropyl)phenothiazin-2-yl methyl ketone

$C_{19}H_{22}N_2OS = 326.5$

CAS—61-00-7

An orange-coloured oil.

Acepromazine Maleate

Proprietary Names. Plégicil. It is an ingredient of Imobilon (for large animals).

$C_{19}H_{22}N_2OS, C_4H_4O_4 = 442.5$

CAS—3598-37-6

A yellow crystalline powder. M.p. 136° to 139°.

Soluble 1 in 27 of water, 1 in 13 of ethanol, and 1 in 3 of chloroform; slightly soluble in ether and light petroleum.

Dissociation Constant. pK_a 9.3.

Partition Coefficient. Log P (octanol/pH 7.4), 2.3.

Colour Tests. Formaldehyde-Sulphuric Acid—blue-violet; Forrest Reagent—red; FPN Reagent—brown-orange; Liebermann's Test—brown; Mandelin's Test—green → red; Marquis Test—yellow-green → red.

Thin-layer Chromatography. System TA—Rf 48; system TB—Rf 26; system TC—Rf 24. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2694; system GF—RI 3230.

High Pressure Liquid Chromatography. System HA— k' 4.1.

Ultraviolet Spectrum. Aqueous acid—243 nm ($A_1^1 = 765$ a), 279 nm; aqueous alkali—245 nm, 283 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1675, 1220, 1265, 1587, 746, 1562 (KBr disk).

Mass Spectrum. Principal peaks at m/z 100, 72, 240, 340, 44, 197, 254, 43 (acepromazine maleate).

Dose. Acepromazine has been given in doses of 6 to 60 mg daily.

Acetaldehyde

Synonyms. Acetic Aldehyde; Aldehyde; Ethanal; Ethyl Aldehyde.

$CH_3 \cdot CHO = 44.05$

CAS—75-07-0

A colourless inflammable liquid. F.p. -123.5° . B.p. 20.2° .

Refractive index, at 20° , 1.3316.

Miscible with water, ethanol, and ether.

Colour Tests. Potassium Dichromate (Method 2)—green; Schiff's Reagent—violet; Sodium Nitroprusside (Method 2)—red.

Gas Chromatography. System GA—RI 372; system GI—retention time 0.7 min.

Mass Spectrum. Principal peaks at m/z 29, 44, 43, 42, 26, 41, 28, 27.

Quantification. GAS CHROMATOGRAPHY. In blood: head-space analysis, detection limit 18 ng/ml, FID—J. M. Christensen *et al.*, *Clinica chim. Acta*, 1981, 116, 389–395.

Disposition in the Body. Acetaldehyde is a major intermediate metabolite of ethanol and is also a metabolite of metaldehyde, paraldehyde, and phenacetin. It undergoes further metabolism by oxidation to acetic acid and, eventually, to carbon dioxide and water. A minor pathway involves condensation with pyruvic acid to form acetoin.

Toxicity. Acetaldehyde is more toxic than ethanol or acetic acid. The maximum permissible atmospheric concentration is 100 ppm.

Acetanilide

Analgesic

Synonym. Antifebrin

N-Phenylacetamide

$C_8H_9NO = 135.2$

CAS—103-84-4

Colourless shining lamellar crystals or white crystalline powder. M.p. 113° to 115°.

Soluble 1 in 200 of water, 1 in 20 of boiling water, 1 in 3.5 of ethanol, 1 in 8 of chloroform, and 1 in 50 of ether; soluble in acetone.

Dissociation Constant. pK_a 0.6 (25°).

Partition Coefficient. Log *P* (octanol), 1.2.

Colour Test. Liebermann's Test—red-orange.

Thin-layer Chromatography. System TD—Rf 45; system TE—Rf 70; system TF—Rf 45. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—acetanilide RI 1358, paracetamol RI 1687.

High Pressure Liquid Chromatography. System HA— k' 0.1; system HD—acetanilide k' 0.5, paracetamol k' 0.1; system HW—acetanilide k' 2.3, paracetamol k' 0.32.

Ultraviolet Spectrum. Aqueous acid—239 nm ($A_1^1 = 815$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1660, 1598, 752, 1538, 1315, 1500 (KBr disk).

Mass Spectrum. Principal peaks at m/z 93, 135, 43, 66, 65, 39, 94, 92; paracetamol 109, 151, 43, 80, 108, 81, 53, 52.

Quantification. GAS CHROMATOGRAPHY. In plasma: FID—N. Buchanan *et al.*, *Br. J. clin. Pharmacol.*, 1980, 9, 525–526.

Disposition in the Body. Rapidly and completely absorbed after oral administration, with maximum plasma concentrations achieved after one to two hours. It is distributed throughout the body. The main metabolic reaction is oxidation to paracetamol through which the analgesic and antipyretic effects of the drug are chiefly exerted; paracetamol is then conjugated with glucuronic acid or sulphate. A minor reaction is deacetylation of

acetanilide to aniline. About 0.1% of an oral dose is excreted unchanged in the urine in 24 hours, about 4% as free paracetamol, 80% as paracetamol conjugates, and 0.05% as aniline. About 0.1% of an oral dose may be eliminated in the faeces.

Toxicity. The main toxic effect is the formation of methaemoglobin due to the production of aniline or other toxic metabolites.

Half-life. Plasma half-life, about 1.5 hours.

Volume of Distribution. About 0.7 litre/kg.

Clearance. Plasma clearance, about 6 ml/min/kg.

Protein Binding. In plasma, not significantly bound.

Dose. Acetanilide was formerly given in doses of 0.36 to 1.2 g daily.

Acetarsol*Antiprotozoal**Synonyms.* Acetarzone; Acetphenarsinum; Osarsolum.*Proprietary Names.* Stovarsol; SVC.

3-Acetamido-4-hydroxyphenylarsonic acid

 $C_8H_{10}AsNO_5 = 275.1$

CAS—97-44-9

A white crystalline powder. M.p. about 240°, with decomposition.

Practically **insoluble** in cold water, moderately soluble in boiling water; practically insoluble in ethanol; soluble in dilute alkalis.

Acetarsol Sodium $C_8H_9AsNNaO_5 \cdot 5H_2O = 387.2$

CAS—5892-48-8 (anhydrous)

White crystals or crystalline powder.

Soluble 1 in 7 of water; practically insoluble in ethanol, chloroform, and ether.

Dissociation Constant. pK_a 3.7, 7.9, 9.3.

Ultraviolet Spectrum. Aqueous acid—281 nm ($A_1^1 = 94$ b); aqueous alkali—250 nm ($A_1^1 = 567$ b), 299 nm ($A_1^1 = 177$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 887, 1538, 784, 823, 1297, 1584 (KBr disk).

Dose. Up to 500 mg daily, for 10 days.

Acetazolamide*Carbonic Anhydrase Inhibitor**Synonyms.* Acetazolam; Acetazoleamide.*Proprietary Names.* Défiltran; Diamox; Diuriwas; Glaucomide; Glauapax; Inidrase.

N-(5-Sulphamoyl-1,3,4-thiadiazol-2-yl)acetamide

 $C_4H_6N_4O_3S_2 = 222.2$

CAS—59-66-5

A fine, white to yellowish-white, crystalline powder. M.p. about 260°, with decomposition.

Soluble 1 in 1400 of water, 1 in 400 of ethanol, and 1 in 100 of acetone; practically insoluble in carbon tetrachloride, chloroform, and ether.

Acetazolamide Sodium*Proprietary Name.* Diamox Sodium $C_4H_5N_4NaO_3S_2 = 244.2$

CAS—1424-27-7

Soluble in water.

Dissociation Constant. pK_a 7.2, 9.0 (25°).

Colour Test. Koppányi–Zwicker Test—red-violet (transient).

Thin-layer Chromatography. *System TD*—Rf 04; *system TE*—Rf 03; *system TF*—Rf 31.

High Pressure Liquid Chromatography. *System HA*— k' 0.1.

Ultraviolet Spectrum. Aqueous acid—265 nm ($A_1^1 = 475$ a); aqueous alkali—240 nm, 291 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1167, 1548, 1316, 1665, 671, 1115 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 180, 42, 45, 44, 64, 100, 222.

Quantification. GAS CHROMATOGRAPHY. In blood, plasma or saliva: detection limit 10 ng, ECD—S. M. Wallace *et al.*, *J. pharm. Sci.*, 1977, 66, 527–530.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In blood or saliva: detection limit 25 pg—K. Kishida *et al.*, *Analyt. Lett. (Part B)*, 1981, 14, 335–347.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In blood, plasma, or urine: sensitivity 50 ng/ml, UV detection—D. J. Chapron and L. B. White, *J. pharm. Sci.*, 1984, 73, 985–989.

Disposition in the Body. Readily absorbed after oral administration. Acetazolamide binds tightly to carbonic anhydrase and will accumulate in tissues in which this enzyme is present, particularly in red blood cells and the renal cortex. About 70 to 90% of a dose is excreted in the urine as unchanged drug in 24 hours but the renal clearance is increased if the urine is alkaline; small amounts of unchanged drug are excreted in the bile.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 10 to 15 $\mu\text{g/ml}$.

Following a single oral dose of 250 mg to 5 subjects, peak plasma concentrations of 10 to 18 $\mu\text{g/ml}$ (mean 14) were attained in 1 to 3 hours; peak erythrocyte concentrations of 13 to 29 $\mu\text{g/ml}$ were reached about 1 hour after the peak plasma concentrations (S. M. Wallace *et al.*, *J. pharm. Sci.*, 1977, 66, 527–530).

TOXICITY. Fatal cases of agranulocytosis, aplastic anaemia, and thrombocytopenia have been reported.

HALF-LIFE. Plasma half-life, about 13 hours; blood and erythrocyte concentrations decrease more slowly.

VOLUME OF DISTRIBUTION. About 0.2 litre/kg.

SALIVA. Plasma: saliva ratio, about 100.

PROTEIN BINDING. In plasma, about 90 to 95%.

Dose. In the treatment of glaucoma 0.25 to 1 g daily.

Acetohexamide

Antidiabetic

Proprietary Names. Dimelor; Dymelor; Ordimele.

1-(4-Acetylbenzenesulphonyl)-3-cyclohexylurea

$\text{C}_{15}\text{H}_{20}\text{N}_2\text{O}_4\text{S} = 324.4$

CAS—968-81-0

A white crystalline powder. M.p. 182° to 187°.

Practically **insoluble** in water and ether; soluble 1 in 230 of ethanol and 1 in 210 of chloroform; soluble in pyridine and in dilute solutions of alkali hydroxides.

Colour Test. Koppanyi-Zwicker Test—violet.

Thin-layer Chromatography. System TD—Rf 39; system TE—Rf 12; system TF—Rf 43.

Ultraviolet Spectrum. Aqueous acid—247 nm ($A_1^1 = 508$ b); aqueous alkali—249 nm ($A_1^1 = 427$ a).

Acetic Acid

Synonyms. Acide Acetique Cristallisable; Concentrated Acetic Acid; Glacial Acetic Acid.

$\text{CH}_3 \cdot \text{COOH} = 60.05$

CAS—64-19-7

A translucent crystalline mass or a clear colourless liquid. M.p. 15°. B.p. about 117°. Refractive index, at 20°, 1.3718.

Miscible with water, ethanol, chloroform, and ether.

Dissociation Constant. pK_a 4.8 (25°).

Colour Test. Ferric Chloride—red.

Mass Spectrum. Principal peaks at m/z 45, 29, 43, 60, 42, 28, 44, 41.

Quantification. GAS CHROMATOGRAPHY. In blood: sensitivity 1 $\mu\text{g/ml}$, FID—D. Lester, *Analyt. Chem.*, 1964, 36, 1810–1812.

Disposition in the Body. Acetic acid occurs as a metabolite of ethanol and also of paraldehyde after its depolymerisation to acetaldehyde. It is further oxidised to carbon dioxide and water.

TOXICITY. The estimated minimum lethal dose is 5 ml and the maximum permissible atmospheric concentration is 10 ppm.

Infra-red Spectrum. Principal peaks at wavenumbers 1165, 1031, 1681, 1531, 905, 1264 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 210, 56, 43, 184, 211, 75, 99, 76.

Quantification. SPECTROFLUORIMETRY. In plasma: limit of detection 200 ng—P. Girgis-Takla and I. Chronos, *Analyst, Lond.*, 1979, 104, 117–123.

GAS CHROMATOGRAPHY. In biological fluids: FID—J. W. Kleber *et al.*, *J. pharm. Sci.*, 1977, 66, 635–638.

Disposition in the Body. Readily absorbed after oral administration and rapidly metabolised to (–)-1-hydroxyhexamide which has about 2.5 times the hypoglycaemic activity of the unchanged drug. Minor metabolites include 4'-trans-hydroxyacetohexamide, 4'-trans-hydroxy-1-hydroxyhexamide and, to a lesser extent, the 4'-cis-, 3'-cis-, and 3'-trans-isomers. About 80% of a dose is excreted in the urine in 24 hours, mainly as metabolites.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 20 to 60 $\mu\text{g/ml}$.

Following oral administration of 750 mg of three different tablet formulations to 8 subjects, mean peak plasma-acetohexamide concentrations of about 28, 40, and 44 µg/ml were attained 2 hours after a dose; mean peak plasma concentrations of (–)-1-hydroxyhexamide averaged about 30 µg/ml (J. W. Kleber *et al.*, *J. pharm. Sci.*, 1977, 66, 635–638).

After daily oral doses of 0.5 g to 18 subjects, an average serum concentration of 42 µg/ml was reported 3 to 5 hours after the dose (J. Sheldon *et al.*, *Diabetes*, 1965, 14, 362–367).

TOXICITY. Prolonged hypoglycaemia has been reported.

HALF-LIFE. Plasma half-life, acetohexamide about 1.3 hours, (–)-1-hydroxyhexamide about 5 hours.

PROTEIN BINDING. In plasma, about 96%.

NOTE. For a review of the pharmacokinetics of oral hypoglycaemic agents see L. Balant, *Clin. Pharmacokinet.*, 1981, 6, 215–241.

Dose. 0.25 to 1.5 g daily.

Acetomenaphthone

Vitamin K Activity

Synonyms. Acetomenadiolone; Menadiol Diacetate.

Proprietary Name. It is an ingredient of Pernivit.

2-Methylnaphthalene-1,4-diyl diacetate

$C_{15}H_{14}O_4 = 258.3$

CAS—573-20-6

A white crystalline powder. M.p. 112° to 115°.

Practically **insoluble** in water; slightly soluble in cold ethanol; soluble 1 in 3.3 of boiling ethanol; soluble in acetic acid.

Colour Test. Liebermann's Test—black.

Ultraviolet Spectrum. Dehydrated alcohol—285 nm ($A_1^1 = 245$ b), 322 nm ($A_1^1 = 37$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1210, 1760, 1163, 1070, 775, 1030 (KBr disk).

Dose. 5 to 20 mg daily.

Acetone

Solvent

Synonyms. Cetona; Dimethyl Ketone; 2-Propanone.

$CH_3 \cdot CO \cdot CH_3 = 58.08$

CAS—67-64-1

A clear, colourless, volatile, mobile, inflammable liquid. F.p. –94°. B.p. about 56°. Refractive index 1.3591.

Miscible with water, ethanol, chloroform, and ether.

Partition Coefficient. Log *P* (octanol), –0.2.

Colour Test. Sodium Nitroprusside (Method 1)—red.

Gas Chromatography. System *GA*—RI 469; system *GI*—retention time 2.5 min.

Ultraviolet Spectrum. Aqueous acid—265 nm.

Mass Spectrum. Principal peaks at *m/z* 43, 58, 59, 27, 42, 26, 39, 29.

Quantification. GAS CHROMATOGRAPHY. In plasma or breath: FID—M. D. Trotter *et al.*, *Clinica chim. Acta*, 1971, 35, 137–143.

Disposition in the Body. Absorbed through the lungs and skin. It is excreted in the urine and through the lungs; large amounts are mainly excreted unchanged but small doses may be oxidised to carbon dioxide or utilised in the body as acetate or formate.

Acetone is the main metabolite of isopropyl alcohol; it occurs naturally in the blood and urine of diabetics.

TOXICITY. Acetone is one of the solvents abused in 'glue-sniffing'. Severe toxic effects have been associated with blood concentrations of 200 to 300 µg/ml; a blood concentration of 550 µg/ml has been reported in a fatality. The maximum permissible atmospheric concentration is 1000 ppm. Exposure to 1600 ppm for about 15 minutes causes irritation to the eyes and nose. Up to 20 ml has been ingested without ill-effect.

Acetophenazine

Tranquilliser

Synonym. Acephenazine

10-{3-[4-(2-Hydroxyethyl)piperazin-1-yl]propyl}phenothiazin-2-yl methyl ketone

$C_{23}H_{29}N_3O_2S = 411.6$

CAS—2751-68-0

Acetophenazine Maleate

Synonym. Acetophenazine Dimaleate

Proprietary Name. Tindal

$C_{23}H_{29}N_3O_5S \cdot 2C_4H_4O_4 = 643.7$

CAS—5714-00-1

A fine yellow powder. M.p. about 165°, with decomposition.

Soluble 1 in 10 of water, 1 in 260 of ethanol, 1 in 370 of acetone, 1 in 2850 of chloroform, 1 in 6000 of ether, and 1 in 11 of propylene glycol.

Colour Tests. Formaldehyde-Sulphuric Acid—blue-violet; Forrester Reagent—pink-orange; FPN Reagent—orange; Liebermann's Test—brown; Marquis Test—red-violet.

Thin-layer Chromatography. System TA—Rf 53; system TB—Rf 03; system TC—Rf 25. (Dragendorff spray, positive; FPN reagent, pink; acidified iodoplatinate solution, positive; Marquis reagent, orange.)

Gas Chromatography. System GA—not eluted.

High Pressure Liquid Chromatography. System HA—k' 1.9.

Ultraviolet Spectrum. Aqueous acid—243 nm ($A_1^1 = 500$ a), 278 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1670, 1220, 1265, 1587, 746, 1149 (KBr disk).

Mass Spectrum. Principal peaks at m/z 254, 143, 42, 70, 411, 113, 56, 157.

Dose. 40 to 120 mg of acetophenazine maleate daily; up to 600 mg daily has been given.

Acetorphine

Narcotic Analgesic

(6R,7R,14R) - 3 - O - Acetyl - 7,8 - dihydro - 7 - (1 - hydroxy - 1 - methylbutyl) - 6 - O - methyl - 6,14 - ethenomorphine

$C_{27}H_{35}NO_5 = 453.6$

CAS—25333-77-1

M.p. 193°.

Soluble 1 in 4000 of water; freely soluble in ethanol, chloroform, and ether.

Caution. It is dangerous to smell or taste this substance.

Acetorphine Hydrochloride

Synonym. M183

$C_{27}H_{35}NO_5 \cdot HCl = 490.0$

CAS—25333-78-2

A white, crystalline, hygroscopic powder. M.p. 204°. It is hydrolysed in solution to etorphine and acetic acid.

Soluble 1 in 50 of water and 1 in 10 of ethanol.

Colour Test. Marquis Test—blue-grey → yellow-brown.

Thin-layer Chromatography. System TA—Rf 72. (Acidified iodoplatinate solution, positive; Marquis reagent, grey; acidified potassium permanganate solution, positive.)

High Pressure Liquid Chromatography. System HA—k' 0.4.

Ultraviolet Spectrum. Aqueous acid—284 nm ($A_1^1 = 45$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1200, 1218, 1168, 1760, 1150, 1122 (acetorphine hydrochloride, KBr disk).

**Acetylcarbromal***Sedative**Synonyms.* Acecarbromal; Acetcarbromal.*Proprietary Names.* Abasin; Sedamyl.

1-Acetyl-3-(2-bromo-2-ethylbutyryl)urea

 $C_9H_{15}BrN_2O_3 = 279.1$

CAS—77-66-7

Colourless crystals or white crystalline powder. M.p. 109°.

Soluble 1 in 1000 of water; soluble in ethanol, chloroform, and ether.**Colour Test.** Nessler's Reagent—brown-orange (slow).**Thin-layer Chromatography.** *System TD*—Rf 49; *system TE*—Rf 57; *system TF*—Rf 48.**Gas Chromatography.** *System GA*—RI 1215.**Infra-red Spectrum.** Principal peaks at wavenumbers 1776, 1730, 1183, 1267, 1149, 1236 (Nujol mull).**Mass Spectrum.** Principal peaks at m/z 43, 129, 69, 41, 86, 97, 55, 44.**Dose.** 0.75 to 1.5 g daily.**Acetylcholine Chloride***Parasympathomimetic**Proprietary Name.* Miochol

(2-Acetoxyethyl)trimethylammonium chloride

 $C_7H_{16}ClNO_2 = 181.7$

CAS—51-84-3 (acetylcholine); 60-31-1 (chloride)

A white, very hygroscopic, crystalline powder. M.p. about 150°. **Very soluble** in water yielding unstable solutions; very soluble in ethanol and propylene glycol; freely soluble in chloroform; practically insoluble in ether.

Acetylcholine Bromide $C_7H_{16}BrNO_2 = 226.1$

CAS—66-23-9

Deliquescent colourless crystals or white crystalline powder. Hydrolysed by hot water and alkalis. M.p. 143°.

Freely **soluble** in water; soluble in ethanol; practically insoluble in ether.**Thin-layer Chromatography.** *System TA*—Rf 02; *system TN*—Rf 70; *system TO*—Rf 60. (Acidified iodoplatinate solution, positive.)**Infra-red Spectrum.** Principal peaks at wavenumbers 949, 1089, 869, 1231, 1000, 1740 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 58, 43, 57, 149, 71, 42, 41, 55.**Dose.** Acetylcholine chloride is used as a 1% ophthalmic solution; it was formerly given parenterally in doses of 20 to 200 mg.**Acetylcodeine**

3-O-Methyl-6-O-acetylmorphine

 $C_{20}H_{23}NO_4 = 341.4$

CAS—6703-27-1

M.p. 134° to 135°.

It is a contaminant of codeine and up to 12% may be found in illicit heroin.

Gas Chromatography. *System GA*—RI 2510.**High Pressure Liquid Chromatography.** *System HC*— k' 0.78; *system HS*— k' 0.50.

Ultraviolet Spectrum. Aqueous acid—284 nm ($A_1^1 = 37$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1233, 1731, 1272, 1042, 1055, 1501.

Mass Spectrum. Principal peaks at m/z 341, 282, 229, 42, 43, 59, 342, 204.

Acetylcysteine

Mucolytic/Paracetamol Antidote

Synonym. *N*-Acetylcysteine

Proprietary Names. Airbron; Fabrol; Fluimucil; Mucolyticum; Mucomyst; Nac; Parvolex.

N-Acetyl-L-cysteine

$C_5H_9NO_3S = 163.2$

CAS—616-91-1

A white, crystalline, deliquescent powder. M.p. 104° to 110°.

Soluble 1 in 8 of water and 1 in 2 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 9.5 (30°).

Gas Chromatography. *System GA*—RI 1547.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1530, 1300, 1230, 1275, 1580, 1715 (Nujol mull).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine; detection limit 50 ng/ml, UV detection—P. A. Lewis *et al.*, *J. pharm. Sci.*, 1984, 73, 996–998.

Disposition in the Body. Readily absorbed after oral administration, peak plasma concentrations being attained in 2 to 3 hours; concentrations in the lung are similar to those in plasma. About 20% of a dose is excreted in the urine in 24 hours.

PROTEIN BINDING. In plasma, about 78%.

REFERENCE. D. Rodenstein *et al.*, *Clin. Pharmacokinet.*, 1978, 3, 247–254.

Dose. As a mucolytic, 600 mg daily by mouth. In the treatment of paracetamol overdosage, initially 150 mg/kg by rapid intravenous infusion.

Acetyldigitoxin

Cardiac Glycoside

Synonyms. Acetyldigitoxoside; α -Digitoxin Monoacetate.

Proprietary Name. Acylanid(e)

3 β -[(*O*-3-*O*-Acetyl-2,6-dideoxy- β -D-ribo-hexopyranosyl-(1 \rightarrow 4)-*O*-2,6-dideoxy- β -D-ribo-hexopyranosyl-(1 \rightarrow 4)-2,6-dideoxy- β -D-ribo-hexopyranosyl)oxy]-14-hydroxy-5 β ,14 β -card-20(22)-enolide

$C_{43}H_{66}O_{14} = 807.0$

CAS—1111-39-3

A white hygroscopic crystalline powder. M.p. 217° to 221°.

Soluble 1 in 6100 of water, 1 in 63 of ethanol, and 1 in 12 of chloroform; practically insoluble in ether and light petroleum; soluble in methanol.

Thin-layer Chromatography. System TK—Rf 82. (p-Anisaldehyde reagent, blue; perchloric acid solution, followed by examination under ultraviolet light, red fluorescence.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Disposition in the Body. About 65% of a dose is absorbed after oral administration. It is slowly excreted in the urine, about 20% of a dose being excreted in 6 days; digitoxin accounts for about 60% of the urinary material. About 15 to 20% of a dose is eliminated in the faeces over a period of 18 days.

HALF-LIFE. Plasma half-life, about 8 to 9 days.

PROTEIN BINDING. In plasma, about 80%.

REFERENCE. G. Bodem *et al.*, *Arzneimittel-Forsch.*, 1975, 25, 1448-1452.

Dose. Maintenance, 100 to 200 µg daily.

Acinitrazole

Antiprotozoal

Synonyms. Aminitroazole; Nithiamide.

Proprietary Names. Tricosil; Trigamma.

N-(5-Nitrothiazol-2-yl)acetamide

$C_5H_5N_3O_3S = 187.2$

CAS—140-40-9

A buff or yellowish-buff powder. M.p. 264° to 265°; slight decomposition may occur.

Very slightly **soluble** in water; soluble 1 in 300 of ethanol and 1 in 900 of chloroform; slightly soluble in ether; soluble in aqueous solutions of sodium hydroxide and ammonia.

Colour Test. Methanolic Potassium Hydroxide—orange.

Thin-layer Chromatography. System TA—Rf 80. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—237 nm, 345 nm ($A_1^1 = 435$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1314, 1176, 1709, 1215, 818, 740.

Dose. Acinitrazole has been given in doses of 200 to 400 mg daily.

Aconitine

Alkaloid

Synonym. Acetylbenzoylaconine

8-Acetoxy-3,11,18-trihydroxy-16-ethyl-1,6,19-trimethoxy-4-methoxymethylaconitan-10-yl benzoate

$C_{34}H_{47}NO_{11} = 645.7$

CAS—302-27-2

An alkaloid present in species of *Aconitum*, including *A. napellus* agg. (Ranunculaceae).

Colourless crystals or white crystalline powder. M.p. 196°, with decomposition.

Soluble 1 in 4500 of water, 1 in 40 of ethanol (90%), 1 in 3 of chloroform, 1 in 70 of ether, and 1 in 2800 of light petroleum.

Aconitine Nitrate

$C_{34}H_{47}NO_{11} \cdot HNO_3 = 708.8$

CAS—6509-18-8

Colourless crystals or white crystalline powder. M.p. about 200°, with decomposition.

Soluble in water and ethanol.

Dissociation Constant. pK_a 8.1 (25°).

Partition Coefficient. Log *P* (ether), 0.8.

Thin-layer Chromatography. System TA—Rf 68; system TB—Rf 08; system TC—Rf 39. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—234 nm ($A_1^1 = 233$ a), 275 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1092, 1273, 1713, 1235, 710, 1020 (KBr disk). (See below)

Mass Spectrum. Principal peaks at *m/z* 105, 554, 540, 43, 45, 77, 31, 29.

**Disposition in the Body.**

TOXICITY. Aconitine affects both the heart and the central nervous system and is one of the most potent and quick-acting poisons. It is well absorbed from the gastro-intestinal tract and death may occur within a few minutes. The estimated minimum lethal dose is 2 mg of aconitine, 5 ml of aconite tincture (25% v/v) or 1 g of aconite root, although recovery after ingestion of 10 mg of aconitine has been reported.

Acriflavine*Antiseptic*

Synonym. Acriflavine Hydrochloride

Proprietary Names. Diacrid; Panflavin.

A mixture of 3,6-diamino-10-methylacridinium chloride hydrochloride and 3,6-diaminoacridine dihydrochloride, the latter being present to the extent of approximately one-third.

$C_{14}H_{14}ClN_3 \cdot HCl = 296.2$; $C_{13}H_{11}N_3 \cdot 2HCl = 282.2$

CAS—8063-24-9

An orange-red to red crystalline powder. A precipitate may form in aqueous solutions on dilution or on standing.

Soluble 1 in about 3 of water and 1 in 40 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 9.1 (25°).

Colour Test. Marquis Test—yellow → red.

Thin-layer Chromatography. *System TA*—four spots at R_f 0.7, 2.2, 2.8, and 6.2. (Location under ultraviolet light, yellow-green fluorescence.)

Ultraviolet Spectrum. Aqueous acid—262 nm ($A_1^1 = 1515$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1631, 1590, 1171, 1181, 1316, 1242.

Adiphenine*Anticholinergic*

2-Diethylaminoethyl diphenylacetate

$C_{20}H_{25}NO_2 = 311.4$

CAS—64-95-9

**Adiphenine Hydrochloride**

Synonym. Spasmolytine

$C_{20}H_{25}NO_2 \cdot HCl = 347.9$

CAS—50-42-0

A white crystalline powder. M.p. 112° to 115°.

Soluble in water, ethanol, and chloroform; practically insoluble in ether.

Colour Tests. Liebermann's Test—brown; Mandelin's Test—green → blue.

Thin-layer Chromatography. *System TA*— R_f 64; *system TB*— R_f 56; *system TC*— R_f 60. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2186.

High Pressure Liquid Chromatography. *System HA*— k' 1.8.

Ultraviolet Spectrum. Aqueous acid—253 nm, 258 nm ($A_1^1 = 14.5$ a), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1736, 1145, 700, 1190, 1500, 746 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 30, 167, 99, 87, 58, 165, 29.

Dose. Adiphenine hydrochloride has been given in doses of 225 to 450 mg daily.

Adrenaline

Sympathomimetic

Synonyms. Epinephrine; Epirenamine; Levorenin; Suprarenin.

Proprietary Names. Bronkaid Mistometer; Dyspné-Inhal; Epiglaufirin; Epinal; Eppy; Glauposine; Simplene; Sus-Phrine; Vaponefrin. It is an ingredient of Asma-Vydrin, Brovon, Ganda, Isopto Epinal, Riddovydin Inhalant, and Rybarvin.

(*R*)-1-(3,4-Dihydroxyphenyl)-2-methylaminoethanol

$C_9H_{13}NO_3 = 183.2$

CAS—51-43-4

A white or creamy-white crystalline powder or granules. It darkens in colour on exposure to air and light. It is unstable in neutral or alkaline solution. M.p. about 212°, with decomposition.

Sparingly **soluble** in water; practically insoluble in ethanol, chloroform, ether, and light petroleum; freely soluble in solutions of mineral acids and boric acid solution, and in solutions of sodium or potassium hydroxide.

Adrenaline Acid Tartrate

Synonyms. Adrenaline Bitartrate; Adrenaline Tartrate; Epinephrine Bitartrate.

Proprietary Names. E1; E2; Epitrate; Liadren; Lyophrin; Medihaler Epi. It is an ingredient of E-Pilo, Mydracaine, PE, and Welder's Flash Drops.

$C_9H_{13}NO_3 \cdot C_4H_6O_6 = 333.3$

CAS—51-42-3

A white to greyish-white or light brownish-grey, crystalline powder. It slowly darkens on exposure to air and light. Incompatible with alkalis.

Soluble 1 in 3 of water and 1 in 520 of ethanol; practically insoluble in chloroform and ether.

Adrenaline Hydrochloride

Proprietary Names. Epifrin; Glaucon; Glycirenin. It is an ingredient of Riddobron Inhalant and Riddofan.

$C_9H_{13}NO_3 \cdot HCl = 219.7$

CAS—55-31-2

Dissociation Constant. pK_a 8.7, 10.2, 12.0 (20°).

Colour Tests. Ammoniacal Silver Nitrate—red-brown/red-brown; Ferric Chloride—green; Folin-Ciocalteu Reagent—blue; Marquis Test—orange→violet; Methanolic Potassium Hydroxide—pink-orange→brown; Nessler's Reagent—black; Palladium Chloride—orange→brown; Potassium Dichromate (Method 1)—green→brown.

Thin-layer Chromatography. System TA—Rf 00; system TB—Rf 00; system TC—Rf 01. (Acidified potassium permanganate solution, positive.)

High Pressure Liquid Chromatography. System HC— k' 0.63.

Ultraviolet Spectrum. Aqueous acid—280 nm ($A_1^{1\%} = 155$ a); aqueous alkali—242 nm, 297 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1253, 1274, 1500, 945, 1224, 871 (KBr disk).

Mass Spectrum. Principal peaks at m/z 44, 42, 124, 165, 163, 123, 93, 65.

Quantification. SPECTROFLUORIMETRY. In plasma: adrenaline and noradrenaline—J. F. O'Hanlon *et al.*, *Analyt. Biochem.*, 1970, 34, 568–581.

GAS CHROMATOGRAPHY. In plasma, erythrocytes, serum, or urine: adrenaline and noradrenaline, detection limit 10^{-7} μg, FID—H. G. Lovelady and L. L. Foster, *J. Chromat.*, 1975, 108, 43–52.

Disposition in the Body. Rapidly destroyed in the gastro-intestinal tract after oral administration; the effects of adrenaline after subcutaneous injection are produced within 5 minutes and appear more slowly than after intramuscular injection. Rapidly taken up by the heart, spleen, several glandular tissues, and adrenergic nerves; only metabolites are detectable in the cerebrospinal fluid. The major metabolic reactions are oxidative deamination and *O*-methylation followed by reduction or by glucuronic acid or sulphate conjugation. About 70 to 95% of an intravenous dose is excreted in the urine; of the excreted material about 80% is *O*-methyl metabolites, 2% is catechol metabolites, and only 1% is unchanged drug. The major urinary metabolite is 4-hydroxy-3-methoxymandelic acid (HMA); other metabolites include 4-hydroxy-3-methoxyphenylacetic acid (homovanillic acid, HVA), conjugated metanephrine, and 4-hydroxy-3-methoxyphenylglycol together with minor amounts of 3,4-dihydroxymandelic acid in free or conjugated form and *N*-methyladrenaline.

Endogenous plasma concentrations of adrenaline in normal subjects are in the range 30 to 160 pg/ml.

TOXICITY. The minimum subcutaneous lethal dose is about 4 mg, but recoveries have occurred after accidental overdosage with 16 mg subcutaneously and 30 mg intravenously, followed by immediate supportive treatment.

PROTEIN BINDING. In plasma, about 50%.

Dose. 200 to 500 µg, subcutaneously or intramuscularly, as a single dose which may be repeated.

Ajmaline

Anti-arrhythmic

Synonym. Rauwolfine

Proprietary Names. Aritmina; Cardiorythmine; Gilurymal; Ritmos.

(17*R*,21*R*)-Ajmalan-17,21-diol

$C_{20}H_{26}N_2O_2 = 326.4$

CAS—4360-12-7

An alkaloid obtained from the root of *Rauwolfia serpentina* (Apocynaceae).

A white or slightly yellowish crystalline powder. M.p. about 195°, with decomposition.

Practically **insoluble** in water; freely soluble in ethanol, chloroform, and glacial acetic acid; sparingly soluble in ether and methanol; soluble in dilute hydrochloric acid.

Ajmaline Hydrochloride

Proprietary Name. Cardiorythmine

$C_{20}H_{26}N_2O_2 \cdot 2HCl \cdot 2H_2O = 435.4$

Crystals. M.p. 140°.

Soluble 1 in 40 of water.

Ajmaline Monoethanolate

$C_{20}H_{26}N_2O_2 \cdot C_2H_5O = 372.5$

CAS—60991-48-2

A white or slightly yellowish crystalline powder.

Practically **insoluble** in water; freely soluble in ethanol, chloroform, and glacial acetic acid; sparingly soluble in ether and methanol.

Dissociation Constant. pK_a 8.2.

Colour Tests. Liebermann's Test—red; Mandelin's Test—red; Marquis Test—violet.

Thin-layer Chromatography. System TA—Rf 62. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—RI 2705.

High Pressure Liquid Chromatography. System HA— k' 2.8 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—245 nm ($A_1' = 223$ a), 289 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 756, 741, 1103, 1092, 1046, 1280.

Quantification. SPECTROFLUORIMETRY. In plasma—E. Welman *et al.*, *Br. J. clin. Pharmac.*, 1977, 4, 549–551.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In blood—D. St. Clemens *et al.*, *Arzneimittel-Forsch.*, 1977, 27, 1128–1130.

THIN-LAYER CHROMATOGRAPHY. In plasma—L. J. Drombowski *et al.*, *J. pharm. Sci.*, 1975, 64, 643–645.

Disposition in the Body. Variably absorbed after oral administration, and mainly metabolised by the liver.

THERAPEUTIC CONCENTRATION.

After intravenous injection of 50 mg to 1 subject, a plasma concentration of about 1.7 µg/ml was reported at 1 minute (E. Welman *et al.*, *Br. J. clin. Pharmac.*, 1977, 4, 549–551).

TOXICITY.

In a fatality due to the ingestion of 2.5 g of ajmaline and 300 mg of diazepam the following postmortem tissue concentrations of ajmaline were reported: blood 10 µg/ml, liver 50 µg/g, urine 44 µg/ml; a blood-alcohol concentration of 1590 µg/ml was also reported (A. R. Alha 1966—personal communication).

Dose. Maintenance, 200 to 300 mg daily.

Albendazole*Anthelmintic (Veterinary)**Proprietary Name.* ValbazenMethyl 5-propylthio-1*H*-benzimidazol-2-ylcarbamate $C_{12}H_{15}N_3O_2S = 265.3$

CAS—54965-21-8

Colourless crystals. M.p. 208° to 210°.

Ultraviolet Spectrum. Aqueous acid—292 nm ($A_1^1 = 370$ b); aqueous alkali—309 nm ($A_1^1 = 742$ b).**Alclofenac***Analgesic**Proprietary Names.* Mervan; Zumaril.

(4-Allyloxy-3-chlorophenyl)acetic acid

 $C_{11}H_{11}ClO_3 = 226.7$

CAS—22131-79-9

A white or slightly yellowish-white crystalline powder. M.p. about 91°.

Slightly soluble in water; soluble 1 in 3 of ethanol, 1 in 4 of chloroform, and 1 in 6 of ether.

Dissociation Constant. pK_a 4.6.**Thin-layer Chromatography.** *System TD*—Rf 18; *system TE*—Rf 04; *system TF*—Rf 28; *system TG*—Rf 12. (*Ludy Tenger reagent*, orange.)**Gas Chromatography.** *System GD*—retention time of methyl derivative 1.13 relative to $n-C_{16}H_{34}$.**High Pressure Liquid Chromatography.** *System HD*— k' 2.6; *system HV*—retention time 0.61 relative to meclofenamic acid.**Ultraviolet Spectrum.** Aqueous acid—277 nm ($A_1^1 = 77$ b); dehydrated alcohol—282 nm ($A_1^1 = 88$ a), 290 nm ($A_1^1 = 78$ a).**Infra-red Spectrum.** Principal peaks at wavenumbers 1258, 1689, 1235, 933, 1016, 1500 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 41, 226, 77, 143, 181, 141, 39, 145.**Quantification.** GAS CHROMATOGRAPHY. In plasma or urine: alclofenac and two metabolites, FID—R. Roncucci *et al.*, *J. Chromat.*, 1971, 62, 135–137.**Disposition in the Body.** Variably absorbed after oral or rectal administration and distributed into the synovial fluid. Metabolised by glucuronic acid conjugation, some conjugation with glycine, deallylation to form 3-chloro-4-hydroxyphenylacetic acid, and hydroxylation to form 3-chloro-4-(2,3-dihydroxypropoxy)phenylacetic acid, which may be methylated; an epoxide

metabolite has also been identified. Up to about 90% of an oral dose is excreted in the urine in 24 hours, mostly as unchanged drug and the glucuronide conjugate.

THERAPEUTIC CONCENTRATION.After an oral dose of 1 g to 10 subjects, a mean peak plasma concentration of 136 µg/ml was attained in about 1 hour; concentrations in the synovial fluid reached a mean peak of 32 µg/ml in 2 hours (G. M. Thomas *et al.*, *Curr. med. Res. Opinion*, 1975, 3, 264–267).**HALF-LIFE.** Plasma half-life, 1.5 to 5.5 hours (mean 2.5).**VOLUME OF DISTRIBUTION.** About 0.1 litre/kg.**PROTEIN BINDING.** In plasma, about 99%.**NOTE.** For a review of the pharmacokinetics of alclofenac see R. N. Brogden *et al.*, *Drugs*, 1977, 14, 241–259.**Dose.** Alclofenac has been given in doses of 1.5 to 3 g daily.

Alcuronium Chloride*Muscle Relaxant*

Synonyms. Allnortoxiferin Chloride; Diallylnortoxiferine Dichloride; Diallyltoxiferine Chloride.

Proprietary Name. Alloferin

NN-Diallylbisnortoxiferinium dichloride pentahydrate

$C_{44}H_{50}Cl_2N_4O_2 \cdot 5H_2O = 827.9$

CAS—23214-96-2 (alcuronium); 15180-03-7 (chloride)

A colourless crystalline powder. No characteristic melting point; a brown colour appears at 220°; still not melted at 350°.

Soluble in water and ethanol; soluble 1 in 5 of methanol.

Colour Tests. Mandelin's Test—blue-violet; Marquis Test—green-brown.

Thin-layer Chromatography. System *TA*—Rf 01. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—255 nm, 291 nm ($A_1^1 = 185$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1495, 1592, 1283, 1650, 1030, 757 (KBr disk).

Quantification. SPECTROFLUORIMETRY. In plasma—J. Walker *et al.*, *Eur. J. clin. Pharmac.*, 1980, 17, 449–457.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 100 ng/ml, electrochemical detection—C. Tovey *et al.*, *J. Chromat.*, 1983, 278; *Biomed. Appl.*, 29, 216–219.

Disposition in the Body. After intravenous administration it is widely distributed throughout the tissues. About 80 to 85% of a dose is excreted in the urine as unchanged drug and about 10 to 15% is secreted in the bile and eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

Following intravenous administration of 0.25 mg/kg to 17 subjects, plasma concentrations of 0.74 to 2.25 µg/ml (mean 1.4) were reported after 3 to 30 minutes (J. Walker *et al.*, *idem.*).

HALF-LIFE. Plasma half-life, about 3 hours; increased in subjects with renal failure.

VOLUME OF DISTRIBUTION. About 0.4 litre/kg.

CLEARANCE. Plasma clearance, about 1.3 ml/min/kg.

PROTEIN BINDING. In plasma, about 40%.

NOTE. For a review of the pharmacokinetics of alcuronium chloride and other muscle relaxants, see M. I. Ramzan *et al.*, *Clin. Pharmacokinet.*, 1981, 6, 25–60.

Dose. Initially 200 to 300 µg/kg intravenously.

Aldosterone*Corticosteroid*

Synonym. Electro cortin

Proprietary Name. Aldocorten

11β,18-Epoxy-18,21-dihydroxypregn-4-ene-3,20-dione

$C_{21}H_{28}O_5 = 360.4$

CAS—52-39-1 (+)

M.p. 164°.

Ultraviolet Spectrum. Methanol—241 nm ($A_1^1 = 437$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1650, 986, 1020, 999, 1062, 1075 (KBr disk).

Dose. Aldosterone has been given in doses of 500 µg intravenously, repeated several times a day.

Aldrin*Insecticide*

Synonym. HHDN

Proprietary Names. Alderstan; Aldrex.

Aldrin usually contains 95% w/w of 1,2,3,4,10,10-hexachloro-1,4,4a,5,8,8a-hexahydro-1,4:5,8-dimethanonaphthalene (HHDN) together with 5% w/w of active related compounds.

$C_{12}H_8Cl_6 = 364.9$

CAS—309-00-2

White crystals. When heated to decomposition it evolves highly toxic fumes of phosgene and hydrogen chloride. The technical grade is a tan to dark brown solid containing 85% or more of HHDN. M.p. 104° (pure grade), 49° to 60° (technical grade). Practically **insoluble** in water; soluble 1 in 20 of ethanol, 1 in 1 of acetone, 1 in 0.55 of benzene, and 1 in 0.33 of carbon tetrachloride; soluble in ether.

Partition Coefficient. Log *P* (octanol), 3.0.

Colour Tests. Nitric-Sulphuric Acid—pink; Sulphuric Acid-Fuming Sulphuric Acid—red (slow).

Gas Chromatography. *System GA*—aldrin RI 1943, dieldrin RI 2110; *system GK*—aldrin retention time 0.88, dieldrin retention time 1.13, both relative to caffeine.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 696, 1036, 835, 723, 1255, 893 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 66, 91, 79, 263, 65, 101, 261, 265; dieldrin 79, 82, 81, 263, 77, 108, 265, 80.

Disposition in the Body. Poorly absorbed after oral ingestion but when dissolved in oils or other lipids it is readily absorbed by the skin and gastro-intestinal tract. It is rapidly metabolised in the body by epoxidation to dieldrin; dieldrin is stored in the body fat and persists for several weeks after the cessation of exposure. It is slowly eliminated in the faeces, mainly as unknown hydrophilic metabolites; a small amount is excreted in the urine as metabolites.

BLOOD CONCENTRATION. Blood concentrations of dieldrin averaging 0.001 μg/ml have been reported in 10 subjects with no occupational exposure to insecticides. Serum concentrations in subjects with low to high occupational exposure averaged 0.001 to 0.002 μg/ml for aldrin and 0.009 to 0.027 μg/ml for dieldrin.

TOXICITY. Severe symptoms may follow absorption of 1 to 3 g; the estimated minimum lethal dose is 5 g. The maximum permissible atmospheric concentration is 0.25 mg/m³ and the maximum permissible concentration in food is 0.1 ppm.

The body fat of a 23-year-old man poisoned by aldrin whilst working in a formulating plant, contained 60 μg/g of dieldrin 15 days after the last exposure; a blood concentration of 0.1 μg/ml was reported 4 months later. The blood concentrations of two men exposed to aldrin in the same plant and showing symptoms of poisoning were 0.28 and 0.13 μg/ml of dieldrin 1 month after the last exposure. In 2 further cases of poisoning, the concentrations of dieldrin in the body fat 3 and 5 weeks after exposure were 149 and 44 μg/g respectively; the corresponding blood concentrations were 0.53 and 0.13 μg/ml (G. Kazantzis *et al.*, *Br. J. ind. Med.*, 1964, 21, 46-51).

HALF-LIFE. Blood half-life, dieldrin 50 to 170 days (mean 97).

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, dieldrin about 1.5.

Aletamine

Analgesic

Synonym. Alfetamine

α-Allylphenethylamine

C₁₁H₁₅N = 161.2

CAS—4255-23-6

Aletamine Hydrochloride

C₁₁H₁₅N.HCl = 197.7

CAS—4255-24-7

White crystals.

Soluble in water.

Colour Tests. Liebermann's Test—orange; Marquis Test—orange.

Thin-layer Chromatography. *System TA*—Rf 59; *system TB*—Rf 37; *system TC*—Rf 40. (Acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive.)

Gas Chromatography. *System GA*—RI 1293.

Ultraviolet Spectrum. Aqueous acid—251 nm, 257 nm (*A*₁¹ = 10 b), 263 nm.

Mass Spectrum. Principal peaks at m/z 70, 120, 43, 91, 39, 103, 71, 65.

Dose. Aletamine hydrochloride has been given in doses of 375 to 750 mg daily.

Alfentanil

Narcotic Analgesic

N-{1-[2-(4-Ethyl-5-oxo-2-tetrazolin-1-yl)ethyl]-4-(methoxymethyl)-4-piperidyl}propionanilide

$C_{21}H_{32}N_6O_3 = 416.5$

CAS—71195-58-9

Alfentanil Hydrochloride

Proprietary Name. Rapifen

$C_{21}H_{32}N_6O_3 \cdot HCl \cdot H_2O = 471.0$

CAS—69049-06-5 (anhydrous); 70879-28-6 (monohydrate)

A white powder. M.p. 135° to 140°.

Readily soluble in water; soluble 1 in 5 of ethanol, 1 in less than 2 of chloroform, and 1 in less than 2 of methanol; practically insoluble in ether.

Dissociation Constant. pK_a 6.5.

Ultraviolet Spectrum. Isopropyl alcohol—258 nm ($A_1^1 = 6.3$ b), 264 nm ($A_1^1 = 4.5$ b), 268 nm ($A_1^1 = 3.1$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1722, 1654, 1252, 1109, 715, 967 (alfentanil hydrochloride, KBr disk).

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 1 ng/ml, AFID—R. Woestenborghs *et al.*, *J. Chromat.*, 1981, 224; *Biomed. Appl.*, 13, 122-127.

RADIOIMMUNOASSAY. In plasma: sensitivity <50 pg/ml—M. Michiels *et al.*, *J. Pharm. Pharmac.*, 1983, 35, 86-93.

Disposition in the Body.

THERAPEUTIC CONCENTRATION.

Following an intravenous injection of 50 µg/kg to 2 subjects, a mean plasma concentration of 0.54 µg/ml was reported at 1 minute, decreasing to 0.038 µg/ml at 1 hour (M. Michiels *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, about 1.5 hours.

VOLUME OF DISTRIBUTION. About 0.5 to 1.0 litre/kg.

CLEARANCE. Plasma clearance, about 3 to 8 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, 1.6.

PROTEIN BINDING. In plasma, about 90% (concentration-dependent; decreases at plasma concentrations greater than 0.1 µg/ml).

NOTE. For a review of alfentanil see L. E. Mather, *Clin. Pharmacokinet.*, 1983, 8, 422-446.

Dose. Initially the equivalent of up to 500 µg of alfentanil intravenously, followed by supplementary doses of 250 µg. With assisted ventilation, an initial dose of 30 to 50 µg/kg intravenously may be given.

Allobarbitone

Barbiturate

Synonyms. Allobarbitol; Diallylbarbitone; Diallylmalonylurea; Diallylmalum.

Proprietary Name. It is an ingredient of Dialog.

5,5-Diallylbarbituric acid

$C_{10}H_{12}N_2O_3 = 208.2$

CAS—52-43-7

A white crystalline powder. M.p. about 173°.

Soluble 1 in 700 of water, 1 in 15 of ethanol, and 1 in 20 of ether; soluble in solutions of alkalis.

Dissociation Constant. pK_a 7.8 (25°).

Colour Tests. Koppanyi-Zwicker Test—violet; Mercurous Nitrate—black; Vanillin Reagent—brown-orange/violet (transient).

Thin-layer Chromatography. *System TD*—Rf 50; *system TE*—Rf 31; *system TF*—Rf 66; *system TH*—Rf 53. (Mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown.)

Gas Chromatography. *System GA*—RI 1606; *system GF*—RI 2340.

High Pressure Liquid Chromatography. *System HG*— k' 2.46; *system HH*— k' 1.33.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—241 nm ($A_1^1 = 460$ a); M sodium hydroxide (pH 13)—256 nm ($A_1^1 = 356$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1687, 1315, 925, 1219, 847, 1640 (KBr disk).

Mass Spectrum. Principal peaks at m/z 41, 167, 124, 39, 80, 53, 68, 141.

Quantification. See under Amylobarbitone.

Disposition in the Body. Absorbed after oral administration. It may persist unchanged in the body for up to one week; about 10 to 35% of a dose is slowly excreted in the urine unchanged.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 15 to 40 µg/ml.

Infra-red Spectrum. Principal peaks at wavenumbers 1692, 1587, 916, 1224, 1235, 956 (KBr disk).

TOXICITY. The estimated minimum lethal dose is 2 g. Plasma concentrations of 50 µg/ml or more are usually toxic.

Dose. Allobarbitone has been given in doses of 90 to 200 mg daily.

Allopurinol

Xanthine-oxidase Inhibitor

Synonyms. HPP; Isopurinol.

Proprietary Names. Alloprin; Allopur; Aluline; Apurin; Caplenal; Capurate; Cosuric; Foligan; Lopurin; Progout; Purinol; Uriscel; Zylprim; Zyloric.

1H-Pyrazolo[3,4-d]pyrimidin-4-ol

$C_5H_4N_4O = 136.1$

CAS—315-30-0

A white microcrystalline powder. No characteristic melting point; it is unchanged up to 300°, after which it begins to darken and at an indefinite high temperature it chars and decomposes. Very slightly **soluble** in water and ethanol; practically insoluble in chloroform and ether; soluble in dimethylformamide and in dilute solutions of alkali hydroxides.

Dissociation Constant. pK_a 9.4.

Colour Test. Folin-Ciocalteu Reagent—grey-blue.

Gas Chromatography. *System GA*—RI 882.

Ultraviolet Spectrum. Aqueous acid (prepared by dissolving in alkali and diluting with acid)—250 nm ($A_1^1 = 563$ a); aqueous alkali—257 nm ($A_1^1 = 523$ a).

Mass Spectrum. Principal peaks at m/z 136, 135, 52, 28, 137, 109, 29, 18.

Quantification. **GAS CHROMATOGRAPHY—MASS SPECTROMETRY.** In serum or urine: allopurinol and oxypurinol, sensitivity 25 ng/ml for allopurinol—C. Lartigue-Mattei *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 211–216.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: allopurinol and oxypurinol, detection limit 100 ng/ml, UV detection—H. Breithaupt and G. Goebel, *J. Chromat.*, 1981, 226; *Biomed. Appl.*, 15, 237–242.

Disposition in the Body. Rapidly absorbed after oral administration; bioavailability about 90%. The major metabolite, oxypurinol (alloxanthine), is active but less potent than allopurinol. Subjects with a genetic deficiency of xanthine oxidase are unable to metabolise allopurinol to oxypurinol. The excretion of unchanged drug appears to vary with acute or chronic

administration, less than 10% of a single dose being excreted unchanged in the urine whereas about 30% is excreted in the urine as unchanged drug after chronic administration. Most of the remainder of a dose is slowly excreted in the urine as oxypurinol; about 20% of a dose is eliminated in the faeces in 72 hours.

THERAPEUTIC CONCENTRATION. Oxypurinol accumulates during chronic administration and may contribute significantly to the therapeutic effect.

Following a single oral dose of 300 mg given to 6 subjects, peak plasma concentrations of 1.4 to 2.6 µg/ml (mean 2) of allopurinol and 4.4 to 7.8 µg/ml (mean 6.3) of oxypurinol were attained in about 0.5 to 2 hours and 2 to 5 hours respectively (H. Breithaupt and M. Tittel, *Eur. J. clin. Pharmac.*, 1982, 22, 77–84).

Following daily oral administration of 300 mg to 7 subjects, steady-state serum concentrations of oxypurinol, determined immediately prior to a dose, were reported to range from 3.4 to 19.4 µg/ml (mean 9.7) (G. P. Rodnan *et al.*, *J. Am. med. Ass.*, 1975, 231, 1143–1147).

HALF-LIFE. Plasma half-life, allopurinol about 0.5 to 2 hours, oxypurinol 12 to 40 hours.

VOLUME OF DISTRIBUTION. About 0.6 litre/kg.

CLEARANCE. Plasma clearance, about 11 ml/min/kg.

PROTEIN BINDING. In plasma, allopurinol less than 5%, oxypurinol about 17%.

Dose. 100 to 600 mg daily.

A pale or dull yellow crystalline powder. It darkens on exposure to light. M.p. of barbaloin about 148°. It quickly forms a monohydrate, m.p. 70° to 80°.

Almost completely **soluble** 1 in 130 of water; soluble 1 in 20 of ethanol; soluble in acetone; very slightly soluble in chloroform and ether.

Colour Tests. Ferric Chloride—brown; Folin–Ciocalteu Reagent—blue; Liebermann's Test—black; Millon's Reagent—pink → red.

Ultraviolet Spectrum. Aqueous acid—245 nm, 253 nm, 300 nm; aqueous alkali—268 nm.

Allyloestrenol

Progestational Steroid

Synonym. Allylestrenol

Proprietary Names. Gestanin; Gestanon.

17α-Allylestr-4-en-17β-ol

C₂₁H₃₂O = 300.5

CAS—432-60-0

Crystals. M.p. 80°.

Practically **insoluble** in water; soluble in ethanol, chloroform, and ether.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 905, 1008, 999, 1020, 1101, 985 (Nujol mull).

Dose. Allyloestrenol has been given in doses of 5 to 20 mg daily.

Aloin

Purgative

A crystalline substance extracted from aloes and consisting almost entirely of barbaloin, 10-β-D-glucopyranosyl-1,8-dihydroxy-3-hydroxymethylanthrone.

C₂₁H₂₂O₉ = 418.4

CAS—8015-61-0; 1415-73-2 (barbaloin)

Dose. Aloin has been given in doses of 13 to 60 mg.

Aloxiprin

Analgesic

Proprietary Names. Palaprin Forte; Rumatral.

A polymeric condensation product of aluminium oxide and aspirin which contains about 83% of total salicylates.

CAS—9014-67-9

A fine white or slightly pink powder.

Practically **insoluble** in water, ethanol, and ether; soluble 1 in 200 of chloroform.

Thin-layer Chromatography. *System TD*—Rf 04; *system TE*—Rf 09; *system TF*—Rf 10.

Ultraviolet Spectrum. Aqueous acid—231 nm; aqueous alkali—298 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1597, 1198, 1562, 1220, 1745, 760 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 45, 60, 120, 42, 92, 138, 44.

Disposition in the Body. Aloxiprin is hydrolysed to aspirin in the gastro-intestinal tract.

Dose. Up to 100 mg/kg daily, by mouth.

Alpha Tocopheryl Acetate

Vitamin E Activity

Synonyms. α -Tocopherol Acetate; *dl*- α -Tocopherol Acetate; α -Tocopheryl Acetate; Vitamin E Acetate.

Proprietary Names. Aquasol E; Ephynal; Evion; Tocomine; Tokols (*d*); Vita-E (*d*).

(\pm)- α -Tocopherol acetate

$C_{31}H_{52}O_3 = 472.8$

CAS—7695-91-2

A clear, slightly greenish-yellow, viscous, oily liquid. Relative density 0.952 to 0.966.

Practically **insoluble** in water; soluble in ethanol; freely soluble in dehydrated alcohol, chloroform, and ether.

Ultraviolet Spectrum. Methanol—284 nm ($A_1^1 = 43$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1210, 1755, 1075, 1105, 1160, 1250 (thin film).

Alphadolone

General Anaesthetic

Synonym. Alfadolone

3 α ,21-Dihydroxy-5 α -pregnane-11,20-dione

$C_{21}H_{32}O_4 = 348.5$

CAS—14107-37-0

M.p. 167° to 170°.

Alphadolone Acetate

Synonym. It is an ingredient of Alphadione (with alphaxalone).

Proprietary Names. It is an ingredient of Alfatesin(e), Alfathesin, Althesin, and Saffan (vet.).

$C_{23}H_{34}O_5 = 390.5$

CAS—23930-37-2

A white to creamy-white powder. M.p. 175° to 181°.

Practically **insoluble** in water; soluble 1 in 15 of ethanol and 1 in 2 of chloroform.

Colour Tests. Antimony Pentachloride—yellow; Naphthol-Sulphuric Acid—orange-brown/orange; Sulphuric Acid—yellow.

Thin-layer Chromatography. Alphadolone acetate: *system TD*—Rf 35; *system TE*—Rf 71; *system TF*—Rf 40; *system TP*—Rf 59; *system TQ*—Rf 22; *system TR*—Rf 80; *system TS*—Rf 45, streaking may occur. (*p*-Toluenesulphonic acid solution, positive.)

Ultraviolet Spectrum. Alphadolone acetate: methanol—290 nm (A_1^1 = about 2).

Infra-red Spectrum. Principal peaks at wavenumbers 1228, 1758, 1710, 1278, 1010, 1043 (alphadolone acetate, KBr disk).

Mass Spectrum. Principal peaks at m/z 317, 43, 271, 147, 289, 390, 95, 81 (alphadolone acetate).

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, ECD—A. J. Pateman, *J. Chromat.*, 1981, 226; *Biomed. Appl.*, 15, 213–218.

Disposition in the Body. Rapidly and widely distributed after injection. Alphadolone acetate is metabolised in the liver to alphadolone and alphadolone glucuronide which are excreted in the urine. Alphadolone is considered to be about 50% as potent an anaesthetic as alphaxalone.

PROTEIN BINDING. In plasma, 20 to 40%.

Dose. See under Alphaxalone.

Alphaprodine

Narcotic Analgesic

Synonym. Prisilidene

(\pm)-*cis*-1,3-Dimethyl-4-phenyl-4-piperidyl propionate

$C_{16}H_{23}NO_2 = 261.4$

CAS—77-20-3; 15867-21-7 (\pm)

Practically **insoluble** in water; soluble in chloroform.

Alphaprodine Hydrochloride

Proprietary Name. Nisentil

$C_{16}H_{23}NO_2 \cdot HCl = 297.8$

CAS—561-78-4 (\pm)

A white crystalline powder. M.p. 218° to 220°.

Soluble 1 in 2 of water, 1 in 7 of ethanol, 1 in 47 of acetone, and 1 in 3 of chloroform; very slightly soluble in ether.

Dissociation Constant. pK_a 8.7 (20°).

Colour Tests. Mandelin's Test—blue-grey; Marquis Test—brown-red.

Thin-layer Chromatography. *System TA*—Rf 50; *system TB*—Rf 30; *system TC*—Rf 35. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *Marquis reagent*, red-brown.)

Gas Chromatography. *System GA*—RI 1792.

High Pressure Liquid Chromatography. *System HA*— k' 2.8 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—251 nm, 257 nm ($A_1^1 = 9$ a), 263 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1740, 1178, 1134, 694, 1030, 1055 (KBr disk).

Mass Spectrum. Principal peaks at m/z 172, 187, 84, 57, 42, 188, 44, 43.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 30 ng/ml, FID—D. L. Fung *et al.*, *J. clin. Pharmac.*, 1980, 20, 37–41.

Disposition in the Body. Alphaprodine is a homologue of pethidine but its action is more rapid in onset and of shorter duration.

THERAPEUTIC CONCENTRATION.

After a rapid intravenous injection of 0.5 mg/kg to 6 subjects, plasma concentrations of about 0.8 μ g/ml were measured after 5 minutes, declining to 0.07 μ g/ml at 5 hours (D. L. Fung *et al.*, *ibid.*).

TOXICITY. The estimated minimum lethal dose is 0.1 g. Prolonged use of alphaprodine is liable to produce dependence of the morphine type.

The following postmortem tissue concentrations were reported in an accidental fatality caused by the intravenous administration of 40 mg of alphaprodine: blood 0.62 μ g/ml, liver 0.97 μ g/g, urine 0.30 μ g/ml; a blood-alcohol concentration of 1.7 μ g/ml was also reported (E. Griesemer and G. R. Nakamura, *Bull. int. Ass. forens. Toxicol.*, 1973, 9 (1–2), 5).

HALF-LIFE. Plasma half-life, about 2 hours.

VOLUME OF DISTRIBUTION. About 2 litres/kg.

CLEARANCE. Plasma clearance, about 10 ml/min/kg.

Dose. 20 to 60 mg of alphaprodine hydrochloride by subcutaneous injection, or 10 to 30 mg intravenously.

Alphaxalone

General Anaesthetic

Synonyms. Alfaxalone. It is an ingredient of Alphadione (with alphadolone acetate).

Proprietary Names. It is an ingredient of Alfatesin(e), Alfathesin, Althesin, and Saffan (vet.).

3 α -Hydroxy-5 α -pregnane-11,20-dione

$C_{21}H_{32}O_3 = 332.5$

CAS—23930-19-0

A white to creamy-white powder. M.p. 165° to 171°.

Practically **insoluble** in water; soluble 1 in 10 of ethanol and 1 in 2 of chloroform.

Thin-layer Chromatography. *System TP*—Rf 60; *system TQ*—Rf 22; *system TR*—Rf 90; *system TS*—Rf 72, streaking may occur. (*p-Toluenesulphonic acid solution*, positive.)

Ultraviolet Spectrum. Methanol—290 nm ($A_1^1 =$ about 2).

Infra-red Spectrum. Principal peaks at wavenumbers 1695, 1148, 1220, 1267, 1000, 1252 (KBr disk).

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, AFID—J. W. Sear *et al.*, *J. Pharm. Pharmac.*, 1980, 32, 349–352.

Disposition in the Body. Rapidly and widely distributed following injection. It undergoes almost 100% first-pass metabolism by reduction of the 20-oxo group and conjugation with glucuronic

acid, and is excreted in the urine. About 60% of a dose is excreted in the urine in 24 hours and 80% in 5 days.

THERAPEUTIC CONCENTRATION.

During constant intravenous infusion of 18, 52, and 90 $\mu\text{g}/\text{min}/\text{kg}$, to 22 subjects, mean steady-state plasma concentrations of 1.9, 2.9, and 3.9 $\mu\text{g}/\text{ml}$, respectively, were reported (J. W. Sear and C. Prys-Roberts, *Br. J. Anaesth.*, 1979, 57, 861-865).

HALF-LIFE. Plasma half-life, about 0.5 hour.

VOLUME OF DISTRIBUTION. About 0.8 litre/kg.

CLEARANCE. Plasma clearance, about 20 ml/min/kg.

PROTEIN BINDING. In plasma, 20 to 50%.

NOTE. For a review of the pharmacokinetics of intravenous anaesthetic agents see P. Duvaldestin, *Clin. Pharmacokinet.*, 1981, 6, 61-82.

Dose. A solution containing alphaxalone 9 mg and alphadolone acetate 3 mg/ml has been administered intravenously; doses of 0.05 to 0.075 ml/kg and 10 to 20 ml/hour have been given to induce and maintain anaesthesia, respectively.

Alprazolam

Tranquilliser

Proprietary Name. Xanax

8 - Chloro - 1 - methyl - 6 - phenyl - 4H - 1,2,4 - triazolo[4,3 - a] - [1,4]benzodiazepine

$\text{C}_{17}\text{H}_{13}\text{ClN}_4 = 308.8$

CAS—28981-97-7

A white crystalline powder. M.p. 225° to 231° . Practically **insoluble** in water; soluble in ethanol and methanol; freely soluble in chloroform.

Dissociation Constant. pK_a 2.4.

High Pressure Liquid Chromatography. System *HI*— k' 4.70; system *HK*— k' 2.79.

Ultraviolet Spectrum. Aqueous acid—260 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1490, 1610, 697, 1316, 1540, 827 (KBr disk). Three polymorphic forms may occur.

Mass Spectrum. Principal peaks at m/z 308, 279, 204, 273, 77, 307, 310, 309.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 250 pg/ml, ECD—D. J. Greenblatt *et al.*, *J. Chromat.*, 1981, 225; *Biomed. Appl.*, 14, 202-207.

Disposition in the Body. Readily absorbed after oral administration and undergoes extensive metabolism. The major metabolites are α -hydroxyalprazolam (active) and a benzophenone derivative of alprazolam. About 80% of a dose is excreted in the urine in 72 hours of which 11% is unchanged drug, 15% is α -hydroxyalprazolam, and 9% is the benzophenone metabolite.

Small amounts of desmethylalprazolam and 4-hydroxyalprazolam are also excreted in the urine. About 7% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 1 mg given to 10 subjects, peak plasma concentrations of 0.011 to 0.020 $\mu\text{g}/\text{ml}$ (mean 0.015) were attained in about 1.75 hours. Following daily oral doses of 0.5 mg three times a day to the same subjects, minimum steady-state plasma concentrations of 0.006 to 0.017 $\mu\text{g}/\text{ml}$ (mean 0.011) and a mean maximum steady-state plasma concentration of 0.018 $\mu\text{g}/\text{ml}$ were reported (R. B. Smith *et al.*, *Clin. Pharm.*, 1983, 2, 139-143).

HALF-LIFE. Plasma half-life, 6 to 20 hours (mean 12).

VOLUME OF DISTRIBUTION. About 1 litre/kg.

CLEARANCE. Plasma clearance, about 1 ml/min/kg.

PROTEIN BINDING. In plasma, about 70%.

NOTE. For a review of alprazolam, see G. W. Dawson *et al.*, *Drugs*, 1984, 27, 132-147.

Dose. 1 to 3 mg daily.

Alprenolol

Beta-adrenoceptor Blocking Agent

(\pm)-1-(2-Allylphenoxy)-3-isopropylaminopropan-2-ol

$\text{C}_{15}\text{H}_{23}\text{NO}_2 = 249.4$

CAS—13655-52-2; 23846-70-0 (\pm)

M.p. 57° to 59° .

Alprenolol Hydrochloride

Proprietary Names. Aptin(e); Betacard; Gubernol.

$C_{15}H_{23}NO_2 \cdot HCl = 285.8$

CAS—13707-88-5; 13678-97-2 (\pm)

Colourless crystals or a white crystalline powder. M.p. 108° to 111°.

Soluble 1 in less than 1 of water, 1 in 2 of ethanol, and 1 in 3 of chloroform; soluble in acetone and dilute acetic acid; practically insoluble in ether.

Dissociation Constant. pK_a 9.5 (20°).

Partition Coefficient. Log P (octanol/pH 7.0), 0.5.

Colour Tests. Liebermann's Test—red; Mandelin's Test—brown-violet; Marquis Test—red; Sulphuric Acid—orange.

Thin-layer Chromatography. *System TA*—Rf 52; *system TB*—Rf 11; *system TC*—Rf 12. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1760.

High Pressure Liquid Chromatography. *System HA*— k' 1.2.

Ultraviolet Spectrum. Aqueous acid—270 nm ($A_1^1 = 69$ b), 276 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1242, 746, 1031, 1492, 1079, 916 (KBr disk).

Mass Spectrum. Principal peaks at m/z 72, 30, 56, 73, 249, 98, 234, 102.

Quantification. GAS CHROMATOGRAPHY. In plasma: detection limit 2.5 ng/ml, ECD—C. F. Poole *et al.*, *J. Chromat.*, 1980, 194, 365–377. In serum: detection limit 2 pg, ECD—D. DeBruyne *et al.*, *J. pharm. Sci.*, 1979, 68, 511–512.

Disposition in the Body. Rapidly and almost completely absorbed after oral administration but undergoes extensive first-pass metabolism; bioavailability about 5 to 10%. About 90% of an oral dose is excreted in the urine in 24 hours with about 40% as the glucuronide conjugate of the active metabolite 4-hydroxyalprenolol, 5% as free 4-hydroxyalprenolol, 20 to 30% as alprenolol glucuronide, 1% as desisopropylalprenolol, and less than 1% as unchanged drug; unknown metabolites account for the remainder of the dose.

THERAPEUTIC CONCENTRATION. There is considerable intersubject variation in plasma concentrations and in the ratio of 4-hydroxyalprenolol to alprenolol.

After oral administration of 200 mg to 2 subjects, peak plasma-alprenolol concentrations of 0.07 and 0.22 $\mu\text{g/ml}$ were reported; peak plasma concentrations of the 4-hydroxy metabolite were 0.04 and 0.06 $\mu\text{g/ml}$ (G. Alvan *et al.*, *J. Pharmacokinet. Biopharm.*, 1977, 5, 193–205).

Following oral administration of 200 mg three times a day to 16 subjects, average steady-state plasma-alprenolol concentrations of 0.01 to 0.14 $\mu\text{g/ml}$ (mean 0.04) were reported (P. Collste *et al.*, *Eur. J. clin. Pharmac.*, 1976, 10, 85–88).

TOXICITY.

In 2 fatalities due to the ingestion of about 4 g and 20 g, respectively, the following postmortem tissue-alprenolol concentrations were reported: blood 40 and 43 $\mu\text{g/ml}$, liver 72 and 91 $\mu\text{g/g}$ (S. J. Dickson *et al.*, *J. analyt. Toxicol.*, 1978, 2, 242–244).

HALF-LIFE. Plasma half-life, alprenolol and 4-hydroxyalprenolol about 2 to 3 hours.

VOLUME OF DISTRIBUTION. About 3 litres/kg.

CLEARANCE. Plasma clearance, about 15 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 1.6.

PROTEIN BINDING. In plasma, 80 to 90%.

Dose. 200 to 800 mg of alprenolol hydrochloride daily.

Alverine

Antispasmodic

Synonyms. Dipropyline; Phenpropamine.

N-Ethyl-3,3'-diphenyldipropylamine

$C_{20}H_{27}N = 281.4$

CAS—150-59-4

**Alverine Citrate**

Proprietary Names. Profenil; Spasmavérine; Spasmonal.

$C_{20}H_{27}N \cdot C_6H_8O_7 = 473.6$

CAS—5560-59-8

A white powder. M.p. 100° to 103°.

Slightly **soluble** in water and chloroform; sparingly soluble in ethanol; very slightly soluble in ether.

Colour Tests. Liebermann's Test—orange; Mandelin's Test—grey-green; Marquis Test—orange-red.

Thin-layer Chromatography. *System TA*—Rf 66; *system TB*—Rf 65; *system TC*—Rf 39. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. *System GA*—RI 2142.

High Pressure Liquid Chromatography. *System HA*— k' 1.8.

Ultraviolet Spectrum. Aqueous acid—253 nm, 259 nm ($A_1^1 = 14.4$ b), 264 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 694, 1190, 740, 1075, 1020, 1694 (KBr disk).

Mass Spectrum. Principal peaks at m/z 72, 176, 91, 58, 177, 41, 42, 30.

Dose. The equivalent of 40 to 240 mg of alverine daily.

Amantadine

Antiviral/Antiparkinsonian

Synonym. 1-Adamantanamine
Tricyclo[3.3.1.1^{3,7}]dec-1-ylamine
 $C_{10}H_{17}N = 151.3$
CAS—768-94-5

Crystals.
Sparingly **soluble** in water; soluble in chloroform.

Amantadine Hydrochloride

Proprietary Names. Antadine; Mantadix; Symmetrel; Virofral.

$C_{10}H_{17}N \cdot HCl = 187.7$

CAS—665-66-7

A white crystalline powder. M.p. 360°, with decomposition.

Soluble 1 in 2.5 of water, 1 in about 5 of ethanol, and 1 in 18 of chloroform; practically insoluble in ether.

Amantadine Sulphate

Proprietary Names. Contenton; PK-Merz; Trivaline.

$C_{10}H_{17}N \cdot \frac{1}{2}H_2SO_4 = 200.3$

CAS—31377-23-8

Dissociation Constant. pK_a 10.4.

Partition Coefficient. Log P (octanol/pH 7.4), -0.4 .

Colour Test. Ninhydrin—pink-violet.

Thin-layer Chromatography. System TA—Rf 23; system TB—Rf 19; system TC—Rf 07: (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1257.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1503, 1497, 1316, 1603, 1089, 1517 (amantadine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 94, 151, 57, 95, 40, 41, 58, 108.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 100 ng/ml in plasma and 4 µg/ml in urine, FID—P. M. Bélanger and O. Grech-Bélanger, *J. Chromat.*, 1982, 228; *Biomed. Appl.*, 17, 327–332. In plasma or urine: detection limit 10 ng/ml, ECD—A. Sioufi and F. Pommier, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 33–39.

Disposition in the Body. Slowly but almost completely absorbed after oral administration. It does not appear to be metabolised in the body, about 56% of a dose being excreted in the urine unchanged in 24 hours and about 86% in 4 days.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 150 mg given to 6 subjects, peak plasma concentrations of 0.32 to 0.56 µg/ml (mean 0.4) were attained in about 3 to 4 hours (F. Y. Aoki *et al.*, *Clin. Pharmac. Ther.*, 1979, 26, 729–736).

After oral administration of 100 mg twice daily, steady-state plasma concentrations of 0.1 to 1.1 µg/ml (mean 0.5) were observed in 22 patients (D. J. Greenblatt *et al.*, *J. clin. Pharmac.*, 1977, 17, 704–708).

TOXICITY.

In a fatality involving the ingestion of amantadine, the following postmortem tissue concentrations were reported: blood 21 µg/ml, bile

418.6 µg/ml, liver 135.4 µg/g, urine 1330 µg/ml (P. C. Reynolds and S. Van Meter, *J. analyt. Toxicol.*, 1984, 8, 100).

HALF-LIFE. Plasma half-life, 10 to 30 hours (mean 15).

Dose. Usually 100 to 200 mg of amantadine hydrochloride daily.

Ambazone

Bacteriostat

Proprietary Names. Bridal; Iversal; Primal(s).

4-Amidinohydrazonocyclohexa-2,5-dien-1-one thiosemicarbazone monohydrate

$C_8H_{11}N_7S_2H_2O = 255.3$

CAS—6011-12-7

A brown microcrystalline powder. M.p. 192° to 194°, with decomposition.

Practically **insoluble** in water; very slightly soluble in ethanol; soluble in solutions of acids and of alkali hydroxides.

Colour Test. Palladium Chloride—brown.

Thin-layer Chromatography. System TA—Rf 55; system TB—Rf 00; system TC—Rf 04. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1130, 1515, 1587, 1612, 1639, 1315.

Dose. Ambazone is given as 10-mg lozenges in doses of 30 to 50 mg daily.

Ambenonium Chloride

Anticholinesterase

Synonyms. Ambestigmini Chloridum; Oxazyl.

Proprietary Names. Mysuran; Mytelase.

NN' - [Oxalylbis(iminoethylene)]bis[(2-chlorobenzyl)diethylammonium] dichloride

$C_{28}H_{42}Cl_4N_4O_2 = 608.5$

CAS—7648-98-8 (ambenonium); 115-79-7 (chloride, anhydrous); 52022-31-8 (chloride, tetrahydrate)

A white powder. M.p. about 200°.

Soluble 1 in 5 of water and 1 in 20 of ethanol; slightly soluble in chloroform; practically insoluble in acetone and ether.

Thin-layer Chromatography. System TA—Rf 02. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—271 nm ($A_1^1 = 30$ c), 277 nm ($A_1^1 = 29$ c). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1675, 1505, 767, 806, 1136, 1190 (KBr disk).

Dose. 15 to 100 mg daily; doses of over 200 mg daily have been given.

Ambucetamide

Antispasmodic

Proprietary Name. It is an ingredient of Femerital.

2-Dibutylamino-2-(4-methoxyphenyl)acetamide

$C_{17}H_{28}N_2O_2 = 292.4$

CAS—519-88-0

A white crystalline powder. M.p. 134°.

Practically **insoluble** in water; soluble in ethanol, chloroform, glacial acetic acid, and isopropyl alcohol.

Thin-layer Chromatography. System TA—Rf 73; system TB—Rf 05; system TC—Rf 68. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2235.

Ultraviolet Spectrum. Aqueous acid—235 nm; aqueous alkali—279 nm, 286 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1656, 1513, 1176, 1250, 1026, 820 (KBr disk).

Mass Spectrum. Principal peaks at m/z 248, 44, 249, 121, 136, 29, 164, 192.

Dose. 300 to 600 mg daily.

Ambutonium Bromide*Anticholinergic**Proprietary Name.* It is an ingredient of Aludrox SA.

(3 - Carbamoyl - 3,3 - diphenylpropyl)ethyldimethylammonium bromide

 $C_{20}H_{27}BrN_2O = 391.4$ *CAS—14007-49-9 (ambutonium); 115-51-5 (bromide)*

White crystals. M.p. 228° to 229°, with decomposition.

Soluble 1 in 1.4 of water, 1 in 27 of ethanol, 1 in 500 of acetone, and 1 in 3.5 of chloroform.**Colour Test.** Liebermann's Test—brown-orange.**Thin-layer Chromatography.** *System TA*—Rf 03. (*Acidified iodoplatinate solution*, positive.)**Ultraviolet Spectrum.** Aqueous acid—253 nm, 259 nm ($A_1^1 = 11.5$ b), 265 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 700, 1664, 764, 1590, 1315, 979.**Dose.** 7.5 to 20 mg daily.**Ametazole***Diagnostic Agent (Gastric Secretion)**Synonym.* Betazole

2-(Pyrazol-3-yl)ethylamine

 $C_5H_9N_3 = 111.1$ *CAS—105-20-4*

A viscous liquid.

Ametazole Hydrochloride*Proprietary Names.* Betazol; Histalog. $C_5H_9N_3 \cdot 2\text{HCl} = 184.1$ *CAS—138-92-1*

A white, hygroscopic, crystalline powder. M.p. about 240° after softening at about 215°.

Soluble 1 in 3 of water and 1 in 50 of ethanol; practically insoluble in chloroform; very slightly soluble in ether.**Dissociation Constant.** pK_a 2.2, 9.6 (20°).**Thin-layer Chromatography.** *System TA*—Rf 26; *system TB*—Rf 11; *system TC*—Rf 00. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *Marquis reagent*, brown; *ninhydrin spray*, positive; *acidified potassium permanganate solution*, positive.)**Gas Chromatography.** *System GA*—RI 1390.**Ultraviolet Spectrum.** No significant absorption, 230 to 360 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1563, 1316, 1647, 775, 928, 1044.**Mass Spectrum.** Principal peaks at m/z 82, 30, 81, 83, 55, 54, 42, 27.**Dose.** 500 µg/kg of ametazole hydrochloride by subcutaneous or intramuscular injection.**Amethocaine***Local Anaesthetic**Synonym.* Tetracaine*Proprietary Name.* It is an ingredient of Locan.

2-Dimethylaminoethyl 4-butylaminobenzoate

 $C_{15}H_{24}N_2O_2 = 264.4$ *CAS—94-24-6*

A white or light yellow, waxy solid. M.p. 41° to 46°.

Very slightly **soluble** in water; soluble 1 in 5 of ethanol, 1 in 2 of chloroform, and 1 in 2 of ether.**Amethocaine Hydrochloride***Synonyms.* Butethanol; Dicainum.*Proprietary Names.* Anethaine; Contralgine; Decicain; Pantocain; Pontocaine Hydrochloride. It is an ingredient of Biosone GA, Eludril (spray), Norgotin, and Riddofan. $C_{15}H_{24}N_2O_2 \cdot \text{HCl} = 300.8$ *CAS—136-47-0*

A white, hygroscopic, crystalline powder. It melts at about 148° or may occur in either of two polymorphic modifications which melt at about 134° and 139°. Mixtures of the forms may melt within the range 134° to 147°.

Soluble 1 in 7.5 of water, 1 in 40 of ethanol, and 1 in 30 of chloroform; practically insoluble in acetone and ether.**Dissociation Constant.** pK_a 8.5 (20°).**Colour Tests.** Aromaticity (Method 2)—yellow/red; Liebermann's Test (100°)—blue.**Thin-layer Chromatography.** *System TA*—Rf 57; *system TB*—Rf 15; *system TC*—Rf 32; *system TL*—Rf 16. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—amethocaine RI 2219, 4-aminobenzoic acid RI 1547; *system GF*—RI 2715.

High Pressure Liquid Chromatography. *System HA*— k' 2.0; *system HQ*— k' 16.25; *system HR*— k' 1.33.

Ultraviolet Spectrum. Aqueous acid—229 nm ($A_1^1 = 561$ a), 281 nm, 312 nm; aqueous alkali—227 nm, 303 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1600, 1286, 1174, 1688, 1126, 1532 (amethocaine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 71, 150, 176, 72, 193, 105, 59 (no peaks above 200); 4-aminobenzoic acid 137, 120, 92, 65, 39, 138, 121, 63.

Disposition in the Body. Amethocaine is rapidly hydrolysed in the blood to 4-aminobenzoic acid; it is completely metabolised within one hour of injection. It can rarely be isolated from blood even within a few minutes of administration. The maximum amount that may be safely administered by injection is probably 50 mg.

Dose. 5 to 20 mg of amethocaine hydrochloride (0.5% solution) is injected for spinal anaesthesia; 0.5 to 2% solutions have been used for surface anaesthesia.

Ametryne

Herbicide

Synonym. Ametryn

Proprietary Name. Gesapax

2-Ethylamino-4-isopropylamino-6-methylthio-1,3,5-triazine

$C_9H_{17}N_5S = 227.3$

CAS—834-12-8

Colourless crystals. M.p. 84° to 86°.

Very slightly **soluble** in water; soluble in chloroform and methanol.

Thin-layer Chromatography. *System TA*—Rf 76. (*Dragendorff spray*, positive.)

Gas Chromatography. *System GA*—RI 1775.

Infra-red Spectrum. Principal peaks at wavenumbers 1515, 1595, 1294, 1166, 806, 1140 (KBr disk).

Amicarbalide

Antiprotozoal (Veterinary)

1,3-Bis(3-amidinophenyl)urea

$C_{15}H_{16}N_6O = 296.3$

CAS—3459-96-9

Amicarbalide Isethionate

Proprietary Name. Diampron

$C_{19}H_{28}N_6O_9S_2 = 548.6$

CAS—3671-72-5

A white or slightly cream-coloured powder. M.p. 200° to 204°.

Soluble 1 in less than 1 of water and 1 in 250 of ethanol; practically insoluble in chloroform and ether.

Colour Tests. Aromaticity (Method 2)—yellow/orange; Liebermann's Test (100°)—yellow.

Thin-layer Chromatography. *System TA*—Rf 05, streaking. (*Acidified iodoplatinate solution*, positive.)

Ultraviolet Spectrum. Aqueous acid—231 nm ($A_1^1 = 1236$ a), inflexion at 256 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1195, 1590, 1672, 1250, 1562, 1052 (KBr disk).

Amidephrine*Sympathomimetic**Synonym.* Amidefrine

3-(1-Hydroxy-2-methylaminoethyl)methanesulphonanilide

 $C_{10}H_{16}N_2O_3S = 244.3$

CAS—3354-67-4

Crystals. M.p. 159° to 161°.

Amidephrine Mesylate $C_{10}H_{16}N_2O_3S \cdot CH_4O_3S = 340.4$

CAS—1421-68-7

A white crystalline solid. M.p. 207° to 209°.

Soluble 1 in about 5 of water; very slightly soluble in chloroform.**Dissociation Constant.** pK_a 9.1.**Colour Test.** Mandelin's Test—violet.**Thin-layer Chromatography.** *System TA*—Rf 15; *system TB*—Rf 00; *system TC*—Rf 01. (Acidified potassium permanganate solution, positive.)**Gas Chromatography.** *System GA*—not eluted.**Ultraviolet Spectrum.** Aqueous acid—272 nm ($A_1^1 = 22$ a).**Infra-red Spectrum.** Principal peaks at wavenumbers 1101, 1153, 1270, 799, 1207, 1316.**Mass Spectrum.** Principal peaks at m/z 44, 42, 147, 120, 65, 43, 45, 39.**Use.** A 0.1% solution of amidephrine mesylate has been used as a nasal decongestant.**Amidopyrine***Analgesic**Synonyms.* Amidazofen; Amidopyrine-Pyramidon; Aminophenazone; Aminopyrine; Dimethylaminoantipyrine; Dimethylaminophenazone.

4-Dimethylamino-1,5-dimethyl-2-phenyl-4-pyrazolin-3-one

 $C_{13}H_{17}N_3O = 231.3$

CAS—58-15-1

Small colourless crystals or white crystalline powder. M.p. about 108°.

Soluble 1 in 20 of water, 1 in 2 of ethanol, 1 in 1 of chloroform, and 1 in 13 of ether.

A number of salts of amidopyrine have been used including the ascorbate, gentisate, hydroxyisophthalate and salicylate.

Dissociation Constant. pK_a 5.0 (20°).**Partition Coefficient.** Log P (octanol/pH 7.4), 1.0.**Colour Tests.** Ferric Chloride—blue-violet; Liebermann's Test (100°)—blue; Nitrous Acid—violet (transient).**Thin-layer Chromatography.** *System TA*—Rf 66; *system TD*—Rf 25; *system TE*—Rf 63; *system TF*—Rf 15. (Acidified iodoplatinate solution, positive.)**Gas Chromatography.** *System GA*—RI 1903; *system GB*—RI 1666; *system GC*—RI 2370; *system GF*—RI 2265.**High Pressure Liquid Chromatography.** *System HA*— k' 0.3; *system HD*— k' 0.2; *system HW*— k' 0.32.**Ultraviolet Spectrum.** Aqueous acid—257 nm ($A_1^1 = 443$ c); aqueous alkali—264 nm ($A_1^1 = 353$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1660, 1315, 1126, 750, 700, 1620 (KBr disk).

Mass Spectrum. Principal peaks at m/z 56, 231, 97, 111, 112, 42, 77, 71.

Quantification. GAS CHROMATOGRAPHY. In plasma: detection limit 100 ng/ml, FID—A. Sioufi and D. Colussi, *J. Chromat.*, 1978, 146; *Biomed. Appl.*, 3, 503–507.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In urine: detection limits 120 ng for amidopyrine, 25 ng for 4-acetamidophenazone and 50 ng for 4-aminophenazone, UV detection—K. Shimada and Y. Nagase, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 51–57.

Disposition in the Body. Absorbed after oral administration. It is rapidly and extensively metabolised. About 30 to 50% of a dose is excreted in the urine in 3 days as 4-aminophenazone and its acetyl derivative 4-acetamidophenazone which is the major urinary metabolite; other metabolites found in the urine include two red pigments, rubazonic acid and methylrubazonic acid; dimethylnitrosamine may be formed in the stomach. Less than 5% of a dose is excreted in the urine unchanged.

Toxicity. The use of amidopyrine is discouraged due to the risk of fatal agranulocytosis. The estimated minimum lethal dose is 5 g.

Half-life. Plasma half-life, about 2 to 3 hours.

Protein Binding. In plasma, 25 to 30%.

Dose. Amidopyrine was formerly given in doses of up to 1.5 g in 24 hours.

Amikacin

Antibiotic

6-*O*-(3-Amino-3-deoxy- α -D-glucopyranosyl)-4-*O*-(6-amino-6-deoxy- α -D-glucopyranosyl)-1-*N*-[(2*S*)-4-amino-2-hydroxybutyryl]-2-deoxy-D-streptamine

$C_{22}H_{43}N_5O_{13}$ = 585.6

CAS—37517-28-5

A white crystalline powder. M.p. 201° to 204°, with decomposition.

Sparingly soluble in water.

Amikacin Sulphate

Proprietary Names. Amikin; Biklin.

$C_{22}H_{43}N_5O_{13} \cdot 2H_2SO_4$ = 781.8

CAS—39831-55-5

Freely soluble in water.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1050, 1630, 1120, 1145, 1545, 940 (KBr disk).

Quantification. GAS CHROMATOGRAPHY. In serum: amikacin, gentamicin, and tobramycin, sensitivity 600 ng/ml, ECD—J. W. Mayhew and S. L. Gorbach, *J. Chromat.*, 1978, 151, 133–146.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: amikacin, gentamicin, and tobramycin, sensitivity 1 μ g/ml, fluorescence detection—J. P. Anhalt and S. D. Brown, *Clin. Chem.*, 1978, 24, 1940–1947.

IMMUNOASSAY. In serum: radioimmunoassay—C. Ashby *et al.*, *Clin. Chem.*, 1978, 24, 1734–1737. In serum: fluoroimmunoassay—S. G. Thompson and J. F. Burd, *Antimicrob. Ag. Chemother.*, 1980, 18, 264–268.

BIOASSAY. Aminoglycoside antibiotics in biological fluids—J. M. Broughall, Aminoglycosides, in *Laboratory Methods in Antimicrobial Chemotherapy*, D. S. Reeves *et al.* (Ed.), Edinburgh, Churchill Livingstone, 1978, pp. 194–207.

REVIEW. For a review of methods for the determination of aminoglycoside antibiotics in biological fluids, see S. K. Maitra *et al.*, *Clin. Chem.*, 1979, 25, 1361–1367.

Disposition in the Body. Poorly absorbed after oral administration but rapidly absorbed after intramuscular injection. About 90% of a dose is excreted in the urine unchanged in 24 hours.

Therapeutic Concentration. During treatment, the serum concentration should be in the range 15 to 25 μ g/ml and should be monitored regularly, especially in patients who have renal insufficiency. During multiple dosing, the trough concentration immediately preceding a dose should not exceed 10 μ g/ml.

A single intramuscular dose of 500 mg given to 6 subjects, produced a mean peak serum concentration of 20 μ g/ml in 1.5 hours (R. A. Yates *et al.*, *J. antimicrob. Chemother.*, 1978, 4, 335–341).

Toxicity. Toxic effects may be produced at serum concentrations of 30 μ g/ml or more or, during chronic treatment, if the trough serum concentration exceeds 10 μ g/ml.

The following postmortem tissue concentrations were reported in a patient who died 5 days after discontinuation of amikacin treatment:

serum 2.2 µg/ml, heart 20 µg/g, kidney 794 µg/g, liver 30 µg/g, lungs 48 µg/g, muscle 11 µg/g (M. A. French *et al.*, *Antimicrob. Ag. Chemother.*, 1981, 19, 147–152).

HALF-LIFE. Plasma half-life, 2 to 3 hours.

VOLUME OF DISTRIBUTION. About 0.2 litre/kg.

CLEARANCE. Plasma clearance, about 1 ml/min/kg.

PROTEIN BINDING. In plasma, less than 10%.

NOTE. For a review of the pharmacokinetics of amikacin see D. Andrews, *Can. J. hosp. Pharm.*, 1977, 30, 146–148.

Dose. The equivalent of 15 mg of amikacin/kg daily, given parenterally; maximum of 1.5 g daily. The total dose should not exceed 15 g.

Amiloride

Diuretic

N-Amidino-3,5-diamino-6-chloropyrazine-2-carboxamide

$C_6H_8ClN_7O = 229.6$

CAS—2609-46-3

M.p. 240° to 242°.

Amiloride Hydrochloride

Synonym. Amipramizide

Proprietary Names. Arumil; Midamor; Modamide. It is an ingredient of Amilco, Frumil, Moducen, and Moduretic.

$C_6H_8ClN_7O \cdot HCl \cdot 2H_2O = 302.1$

CAS—2016-88-8 (anhydrous)

A pale yellow to greenish-yellow powder. M.p. 285° to 288°, with decomposition.

Soluble in water and ethyl acetate; soluble 1 in 350 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 8.7.

Colour Tests. Marquis Test—yellow; Sulphuric Acid—yellow.

Thin-layer Chromatography. *System TA*—Rf 24; *system TB*—Rf 00; *system TC*—Rf 01. (Acidified iodoplatinate solution, strong reaction.)

Ultraviolet Spectrum. Aqueous acid—285 nm ($A_1^1 = 731$ a), 361 nm ($A_1^1 = 802$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1634, 1602, 1504, 1686, 1238, 1538 (amiloride hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 187, 42, 171, 229, 86, 144, 170.

Quantification. SPECTROFLUORIMETRY. In plasma, serum, or urine—J. E. Baer *et al.*, *J. Pharmac. exp. Ther.*, 1967, 157, 472–485.

THIN-LAYER CHROMATOGRAPHY-SPECTROFLUORIMETRY. In plasma—K. Reuter *et al.*, *J. Chromat.*, 1982, 233; *Biomed. Appl.*, 22, 432–436.

Disposition in the Body. Incompletely absorbed after oral administration; it does not appear to be metabolised. About 50% of an oral dose is excreted unchanged in the urine and 40% is eliminated in the faeces in 72 hours.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 20 mg to 6 subjects, peak serum concentrations of about 0.05 µg/ml were attained in 4 hours (A. J. Smith and R. N. Smith, *Br. J. Pharmac.*, 1973, 48, 646–649).

HALF-LIFE. Plasma half-life, 6 to 10 hours.

VOLUME OF DISTRIBUTION. About 5 litres/kg.

PROTEIN BINDING. In plasma, not significantly bound.

Dose. 5 to 20 mg of amiloride hydrochloride daily.

Aminacrine

Disinfectant

Synonym. Aminoacridine

9-Aminoacridine

$C_{13}H_{10}N_2 = 194.2$

CAS—90-45-9

Yellow needles. M.p. 241°.

Freely **soluble** in ethanol; soluble in acetone; slightly soluble in chloroform.

Aminacrine Hexylresorcinate

Synonyms. Acrisorcin; Aminacrine 4-Hexylresorcinate.

$C_{13}H_{10}N_2, C_{12}H_{18}O_2 = 388.5$

CAS—7527-91-5

A yellow crystalline powder.

Slightly **soluble** in water and ethanol.

Aminacrine Hydrochloride

Synonym. Acramine Yellow

Proprietary Names. Aminopt; Monacrin.

$C_{13}H_{10}N_2, HCl, H_2O = 248.7$

CAS—134-50-9 (anhydrous)

A yellow crystalline powder. M.p. about 235°.

Soluble 1 in 300 of water; a saturated solution in water is pale yellow with a greenish-blue fluorescence, becoming blue when freely diluted. Soluble 1 in 150 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 9.5 (25°).

Colour Tests. Aromaticity (Method 2)—yellow/red; Liebermann's Test (100°)—red.

Cold *nitric acid* gives a red colour in 15 seconds.

Thin-layer Chromatography. *System TA*—Rf 54. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2240.

Ultraviolet Spectrum. Aqueous acid—260 nm ($A_1^1 = 4442$ a), 313 nm ($A_1^1 = 74$ b), 326 nm ($A_1^1 = 81$ b); methanol—260 nm ($A_1^1 = 4480$ b), 311 nm, 325 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 760, 1556, 1645, 1655, 750, 1612 (KBr disk).

Aminobenzoic Acid

Sunscreen Agent

Synonyms. Amben; PAB; PABA; Pabacidum; Para-aminobenzoic Acid; Vitamin H'.

Proprietary Names. Hill-Shade; Pabagel; Pabanol; Paraminan; Presun 8; RVPaba.

4-Aminobenzoic acid

$C_7H_7NO_2 = 137.1$

CAS—150-13-0

White or slightly yellow crystals or crystalline powder. It gradually darkens on exposure to air and light. M.p. 186° to 189°.

Soluble 1 in 200 of water, 1 in 10 of boiling water, 1 in 8 of ethanol, and 1 in 50 of ether; slightly soluble in chloroform; freely soluble in solutions of alkali hydroxides and carbonates.

Potassium Aminobenzoate

Proprietary Name. Potaba

$C_7H_6KNO_2 = 175.2$

CAS—138-84-1

A crystalline powder.

Very **soluble** in water; less soluble in ethanol; practically insoluble in ether.

Dissociation Constant. pK_a 2.4, 4.9 (25°).

Colour Tests. Coniferyl Alcohol—orange; Diazotisation—red.

Thin-layer Chromatography. *System TA*—Rf 58; *system TD*—Rf 19; *system TE*—Rf 01; *system TF*—Rf 43. (*Acidified potassium permanganate solution*, positive; *Van Urk reagent*, yellow.)

Gas Chromatography. *System GA*—RI 1547.

Ultraviolet Spectrum. Aqueous acid—270 nm ($A_1^1 = 95$ b); aqueous alkali—265 nm ($A_1^1 = 1063$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1597, 1168, 1290, 1665, 1305, 1625 (KBr disk).

Mass Spectrum. Principal peaks at m/z 137, 120, 92, 65, 39, 138, 121, 63.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum or urine: aminobenzoic acid and metabolites, UV detection—N. D. Brown and E. J. Michalski, *J. Chromat.*, 1976, 121, 76–78.

Disposition in the Body. Readily absorbed after oral administration. It is conjugated with aminoacetic acid to form *p*-aminohippuric acid which is excreted in the urine together with a small amount of *p*-aminobenzoyl glucuronide, *p*-acetamidobenzoyl glucuronide, and traces of *p*-acetamidohippuric acid, *p*-acetamidobenzoic acid, and unchanged aminobenzoic acid.

Aminobenzoic acid may be detected in the urine as a metabolite of amethocaine, benzocaine, and procaine.

TOXICITY. Toxic effects are infrequent and are usually associated with plasma concentrations greater than about 600 µg/ml.

Uses. Aminobenzoic acid is used topically as a 5% solution; potassium aminobenzoate has been given orally, in doses of 12 g daily.

Aminocaproic Acid

Haemostatic

Synonyms. EACA; Epsilon Aminocaproic Acid.

Proprietary Names. Amicar; Capralense; Capramol; Ekaprol; Epsikapron; Hemocaprol.

6-Aminohexanoic acid

$C_6H_{13}NO_2 = 131.2$

CAS—60-32-2

Colourless crystals or white crystalline powder. M.p. about 204°, with decomposition.

Soluble 1 in 1.5 of water; slightly soluble in ethanol; practically insoluble in chloroform and ether; freely soluble in solutions of acids and alkalis.

Dissociation Constant. pK_a 4.4, 10.8 (25°).

Infra-red Spectrum. Principal peaks at wavenumbers 1538, 1613, 1098, 1319, 1258, 1203 (KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: detection limits 10 pg and 3 ng for fluorescence or UV detection, respectively—N. A. Farid, *J. pharm. Sci.*, 1979, 68, 249–252.

Disposition in the Body. Readily absorbed after oral administration and widely distributed throughout the body fluids. About 70 to 80% of a dose is excreted in the urine unchanged in 12 hours.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 100 to 400 µg/ml.

HALF-LIFE. Plasma half-life, about 2 to 5 hours.

VOLUME OF DISTRIBUTION. About 0.4 litre/kg.

REFERENCE. For a review of aminocaproic acid see *Aust. J. Pharm.*, 1981, 62, 403–407.

Dose. 3 to 6 g may be given 4 to 6 times daily.

Aminogluthethimide

Antineoplastic

Proprietary Name. Orimeten

3-(4-Aminophenyl)-3-ethylpiperidine-2,6-dione

$C_{13}H_{16}N_2O_2 = 232.3$

CAS—125-84-8

A white crystalline powder. M.p. about 151°.

Very slightly **soluble** in water; freely soluble in organic solvents.

Colour Tests. Coniferyl Alcohol—yellow; Koppányi–Zwicker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. System TD—Rf 32; system TE—Rf 65; system TF—Rf 47.

Gas Chromatography. System GA—RI 2227.

Ultraviolet Spectrum. Aqueous acid—251 nm ($A_1^1 = 18$ b), 257 nm ($A_1^1 = 18$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1695, 1185, 1200, 1515, 1623, 1267 (KCl disk).

Mass Spectrum. Principal peaks at m/z 203, 232, 132, 175, 204, 233, 160, 118.

Quantification. COLORIMETRY. In plasma or urine: sensitivity 2 µg/ml in plasma—F. T. Murray *et al.*, *J. clin. Pharmac.*, 1979, 19, 704–711.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit < 230 ng/ml, UV detection—B. A. Robinson and F. N. Cornell, *Clin. Chem.*, 1983, 29, 1104–1105.

Disposition in the Body. Readily absorbed after oral administration. About 10% of an oral dose is excreted in the urine as unchanged drug in 48 hours; acetamidoglutethimide has been identified as a metabolite. Aminoglutethimide appears to induce its own metabolism.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 500 mg given to 6 subjects, peak plasma concentrations of 5.8 to 6.3 µg/ml (mean 5.9) were attained in 1.3 hours (T. A. Thompson *et al.*, *J. pharm. Sci.*, 1981, 70, 1040–1043).

Steady-state serum concentrations of 4.7 to 32.4 µg/ml (mean 11.5) were reported in 7 subjects receiving chronic treatment with oral doses of 1 g daily (F. T. Murray *et al.*, *J. clin. Pharmac.*, 1979, 19, 704–711).

TOXICITY. The estimated minimum lethal dose is 5 g.

HALF-LIFE. Plasma half-life, about 13 hours following a single dose but appears to decrease during chronic treatment.

VOLUME OF DISTRIBUTION. About 1.4 litre/kg.

CLEARANCE. Plasma clearance, about 1.3 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 0.7.

PROTEIN BINDING. In plasma, about 25%.

Dose. 0.5 to 1 g daily.

Aminohippuric Acid *Diagnostic Agent (Renal Function)*

Synonyms. *p*-Aminobenzoylglycine; PAHA; Para-aminohippuric Acid.

N-4-Aminobenzoylaminoacetic acid

$C_9H_{10}N_2O_3 = 194.2$

CAS—61-78-9

A white crystalline powder, which discolours on exposure to light. M.p. about 195°, with decomposition.

Soluble 1 in 45 of water, 1 in 50 of ethanol, and 1 in 5 of dilute hydrochloric acid; very slightly soluble in carbon tetrachloride, chloroform, and ether; freely soluble, with decomposition, in solutions of alkali hydroxides and carbonates.

Sodium Aminohippurate

Proprietary Name. Nephrotest

$C_9H_9N_2NaO_3 = 216.2$

CAS—94-16-6

Soluble in water.

Dissociation Constant. pK_a 3.6.

Colour Test. Diazotisation—red.

Thin-layer Chromatography. System TA—Rf 55. (*Van Urk reagent*, yellow.)

Ultraviolet Spectrum. Methanol—280 nm ($A_1^1 = 880$ b).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: detection limit 1 µg/ml, UV detection—T. Prueksaritanont *et al.*, *J. Chromat.*, 1984, 306; *Biomed. Appl.*, 31, 89–97.

Disposition in the Body. Aminohippuric acid is a major metabolite of aminobenzoic acid. After intravenous administration it is rapidly excreted in the urine in subjects with normal renal function.

HALF-LIFE. Biological half-life, about 0.2 hour.

Dose. 2 to 30 g of sodium aminohippurate intravenously, to measure renal function.

Aminonitrothiazole

Antiprotozoal (Veterinary)

2-Amino-5-nitrothiazole

$C_3H_3N_3O_2S = 145.1$

CAS—1320-42-9

A greenish-yellow to orange-yellow light powder. M.p. 200°, with decomposition.

Slightly **soluble** in water; soluble 1 in 250 of ethanol and of ether; practically insoluble in chloroform; soluble in dilute mineral acids and propylene glycol.

Colour Test. Diazotisation—violet.

Thin-layer Chromatography. System TA—Rf 75. (Visible yellow spot; *acidified iodoplatinate solution*, strong reaction.)

Gas Chromatography. System GA—not eluted.

Ultraviolet Spectrum. Water—386 nm ($A_1^1 = 1060$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1200, 1623, 1176, 1504, 1515, 1252 (KBr disk).

4-Aminophenol

Synonyms. *p*-Aminophenol; *p*-Hydroxyaniline.

$C_6H_7NO = 109.1$

CAS—123-30-8

Crystals. M.p. about 190°. The commercial product is usually pink; m.p. 186°.

Slightly **soluble** in water; soluble in dehydrated alcohol; practically insoluble in chloroform.

Colour Test. Liebermann's Test—black.

Thin-layer Chromatography. *System TD*—Rf 21; *system TE*—Rf 59; *system TF*—Rf 40. (Ferric chloride solution, violet; acidified potassium permanganate solution, positive; Van Urk reagent, yellow.)

Gas Chromatography. *System GA*—RI 1265.

Ultraviolet Spectrum. Aqueous acid—271 nm ($A_1^1 = 133$ b); aqueous alkali—266 nm (broad) ($A_1^1 = 731$ b); methanol—233 nm ($A_1^1 = 587$ b), 303 nm ($A_1^1 = 177$ b).

Mass Spectrum. Principal peaks at m/z 109, 80, 53, 81, 108, 52, 54, 110.

Disposition in the Body. 4-Aminophenol is a metabolite of aniline, nitrobenzene, and phenazopyridine.

Aminosalicilic Acid

Antituberculous Agent

Synonyms. Aminosalylum; Para-aminosalicylic Acid; PAS; Pasalicylum.

Proprietary Names. Nemasol; Parasal; Teebacin Acid.

4-Amino-2-hydroxybenzoic acid

$C_7H_7NO_3 = 153.1$

CAS—65-49-6

A white bulky powder, which darkens on exposure to air and light. Aqueous solutions are unstable. M.p. 150° to 151°, with effervescence.

Soluble 1 in about 600 of water, 1 in about 20 of ethanol, 1 in 6 of acetone, 1 in 4000 of chloroform, and 1 in 50 of ether.

Calcium Aminosalicylate

Synonym. Aminosalicylate Calcium

$(C_7H_6NO_3)_2Ca \cdot 3H_2O = 398.4$

CAS—133-15-3 (anhydrous)

A white or slightly yellow, hygroscopic, crystalline powder. Aqueous solutions are unstable and darken in colour.

Soluble 1 in 7 to 1 in 10 of water; slightly soluble in ethanol.

Phenyl Aminosalicylate

Synonym. Fenamisal

$C_{13}H_{11}NO_3 = 229.2$

CAS—133-11-9

A white crystalline solid. M.p. 153°.

Practically **insoluble** in water.

Potassium Aminosalicylate

Synonym. Aminosalicylate Potassium

Proprietary Name. Teebacin Kalium

$C_7H_6KNO_3 = 191.2$

CAS—133-09-5

A white to cream-coloured crystalline powder. Aqueous solutions are unstable.

Freely **soluble** in water; sparingly soluble in ethanol; very slightly soluble in chloroform and ether.

Sodium Aminosalicylate

Synonyms. Aminosalicylate Sodium; Pasalicylum Solubile.

Proprietary Names. Eupasal Sodico; Italpas Sodico; Parasal Sodium; Pasalba; Teebacin.

$C_7H_6NNaO_3 \cdot 2H_2O = 211.1$

CAS—133-10-8 (anhydrous); 6018-19-5 (dihydrate)

White or cream-coloured crystals or crystalline powder. Aqueous solutions are unstable.

Soluble 1 in 2 of water; sparingly soluble in ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 1.8 ($-NH_2$), 3.6 ($-COOH$).

Partition Coefficient. Log P (octanol), 0.87.

Colour Tests. Coniferyl Alcohol—orange; Ferric Chloride—violet; Folin-Ciocalteu Reagent—blue; McNally's Test—brown precipitate.

Thin-layer Chromatography. *System TA*—Rf 70; *system TD*—Rf 05; *system TE*—Rf 07; *system TF*—Rf 24. (Location under ultraviolet light, blue fluorescence; ferric chloride solution, violet; acidified potassium permanganate solution, positive; Van Urk reagent, yellow.)

Gas Chromatography. *System GA*—RI 1309.

Ultraviolet Spectrum. Aqueous acid—234 nm ($A_1^1 = 496$ a), 300 nm ($A_1^1 = 330$ a); aqueous alkali—265 nm ($A_1^1 = 846$ a), 300 nm ($A_1^1 = 532$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1301, 1638, 1595, 1510, 805, 1180 (KBr disk).

Mass Spectrum. Principal peaks at m/z 109, 80, 44, 81, 53, 39, 52, 54.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: aminosalicic acid and *p*-acetamidosalicylic acid, sensitivity 500 ng/ml in plasma, fluorescence detection—R. G. Stoll *et al.*, *Res. Commun. chem. Path. Pharmac.*, 1972, 4, 327–338. In plasma: limit of detection 0.5 ng, fluorescence detection—I. L. Honigberg *et al.*, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 266–271.

Disposition in the Body. Readily absorbed after oral administration and widely distributed throughout the body with high concentrations in the kidneys, lungs, and liver. It is metabolised by acetylation to *p*-acetamidosalicylic acid and by conjugation with glycine, producing *p*-aminosalicyluric acid; both metabolites are inactive. More than 80% of a dose is excreted in the urine in 24 hours with about 50% of the dose consisting of *p*-acetamidosalicylic acid; up to 25% of the dose may be excreted as free and acetylated *p*-aminosalicyluric acid, and the remainder is mostly unchanged drug with small amounts of 2,4-dihydroxybenzoic acid.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 4 g of aminosalicic acid to 12 subjects, a mean peak plasma concentration of 50 µg/ml was attained in 3.5 hours; after oral administration of 4 g of sodium aminosalicylate to the same subjects, a mean peak plasma concentration of 155 µg/ml was attained in about 0.8 hour (S. H. Wan *et al.*, *J. pharm. Sci.*, 1974, 63, 708–711).

TOXICITY. Prolonged administration may give rise to toxic symptoms characteristic of the salicylates.

HALF-LIFE. Plasma half-life, aminosalicic acid about 0.5 to 1 hour, *p*-acetamidosalicylic acid about 1.5 hours.

PROTEIN BINDING. In plasma, 60 to 70%.

Dose. 12 g of sodium aminosalicylate daily; up to 20 g daily has been given.

Aminotriazole

Herbicide

Synonyms. Amitrole; ATA.

Proprietary Names. Weedazol. It is an ingredient of a number of proprietary weed-killers.

3-Amino-1,2,4-triazole

$C_2H_4N_4 = 84.1$

CAS—61-82-5

A white crystalline powder. M.p. 159°.

Soluble 1 in 3.5 of water and 1 in 4 of ethanol; practically insoluble in acetone, ether, and non-polar solvents; sparingly soluble in ethyl acetate.

Colour Test. Add sodium hypobromite solution to the sample—orange-red.

Thin-layer Chromatography. System TA—Rf 68. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—not eluted; system GK—not eluted.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1639, 1047, 1534, 1595, 1211, 971 (KBr disk).

Mass Spectrum. Principal peaks at m/z 84, 58, 43, 44, 42, 53, 55, 86.

Amiodarone

Anti-arrhythmic

2-Butylbenzofuran-3-yl 4-(2-diethylaminoethoxy)-3,5-diiodophenyl ketone

$C_{25}H_{29}I_2NO_3 = 645.3$

CAS—1951-25-3

Amiodarone Hydrochloride

Proprietary Names. Cordarone; Cordarone X.

$C_{25}H_{29}I_2NO_3 \cdot HCl = 681.8$

CAS—19774-82-4

A white crystalline powder. M.p. about 161°.

Very slightly **soluble** in water; soluble in ethanol; freely soluble in chloroform.

Dissociation Constant. pK_a 5.6.

Colour Tests. Iodine Test (omitting MnO_2)—positive; Liebermann's Test—brown-yellow; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 72; system TB—Rf 62; system TC—Rf 68. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, yellow.)

Gas Chromatography. System GA—RI 3335; decomposition on column produces two major products, RI 2590 and 2780.

High Pressure Liquid Chromatography. System HA—amiodarone k' 2.4, monodesethylamiodarone k' 1.8.

Ultraviolet Spectrum. Aqueous acid—241 nm; aqueous alkali—251 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1630, 748, 1245, 1558, 1170, 998 (amiodarone hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 36, 87, 84, 58, 56, 44, 38.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: amiodarone and monodesethylamiodarone, sensitivity 100 ng/ml, UV detection—G. C. A. Storey *et al.*, *Ther. Drug Monit.*, 1982, 4, 385–388. In plasma, urine or tissues: amiodarone and monodesethylamiodarone, sensitivity 25 ng/ml in plasma, UV detection—T. A. Plomp *et al.*, *J. Chromat.*, 1983, 273; *Biomed. Appl.*, 24, 379–392.

Disposition in the Body. Slowly and incompletely absorbed after oral administration; distributed to the tissues where it is strongly bound. Metabolised by *N*-dealkylation to monodesethylamiodarone which is the major plasma metabolite during chronic dosing. High concentrations of amiodarone and monodesethylamiodarone are found in the liver, lungs, and adipose tissue. Enterohepatic circulation may occur. Only a small amount is excreted in the urine as unchanged drug.

THERAPEUTIC CONCENTRATION. Accumulates on chronic administration; steady-state plasma concentrations are attained in about one month.

Following oral administration of 400 mg to 7 subjects, peak plasma concentrations of about 0.5 to 1 μg/ml were attained in about 7 hours. After administration of 200 mg 8-hourly to 6 subjects for one month, plasma concentrations determined immediately before the morning dose ranged from 0.75 to 2.8 μg/ml (mean 1.5) (F. Andreasen *et al.*, *Eur. J. clin. Pharmac.*, 1981, 19, 293–299).

During chronic treatment with 400 mg daily to 33 subjects, mean steady-state plasma concentrations of 2.2 μg/ml of amiodarone and 2.0 μg/ml of monodesethylamiodarone were reported (R. J. Flanagan *et al.*, *J. Pharm. Pharmac.*, 1982, 34, 638–643).

HALF-LIFE. Plasma half-life during chronic dosing, 14 to 107 days (mean 50).

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, 1.3.

PROTEIN BINDING. In plasma, extensively bound.

NOTE. For a review of the pharmacokinetics of amiodarone see R. Latini *et al.*, *Clin. Pharmacokinet.*, 1984, 9, 136–156.

Dose. Initially 600 mg of amiodarone hydrochloride daily; maintenance, 200 to 400 mg daily.

Amiphenazole

Respiratory Stimulant

Synonym. DAPT

5-Phenylthiazole-2,4-diamine

$C_9H_9N_3S$ = 191.3

CAS—490-55-1

Flakes which turn brown on exposure to light and air. M.p. 163° to 164°, with decomposition.

Amiphenazole Hydrochloride

Synonym. Amiphenazole Chloride

Proprietary Names. Daptazile; Daptazole.

$C_9H_9N_3S \cdot HCl$ = 227.7

CAS—942-31-4

A white, fine crystalline or granular, mobile powder. Aqueous solutions hydrolyse slowly. M.p. 236°.

Soluble 1 in 16 of water and 1 in 50 of ethanol; slightly soluble in acetone, chloroform, and ether.

Colour Test. Liebermann's Test (100°)—green-blue.

Thin-layer Chromatography. *System TA*—Rf 61; *system TB*—Rf 02; *system TC*—Rf 33. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GB*—RI 1150; *system GC*—RI 2563.

Ultraviolet Spectrum. Aqueous acid—230 nm (A_1^1 = 998 a), 261 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1495, 1637, 688, 750, 1665, 1050 (KBr disk).

Mass Spectrum. Principal peaks at m/z 191, 121, 77, 104, 122, 43, 51, 192.

Dose. Amitriptyline hydrochloride has been given parenterally in doses of 100 to 150 mg.

Amitriptyline

Antidepressant

3-(10,11-Dihydro-5H-dibenzo[*a,d*]cyclohepten-5-ylidene)-*NN*-dimethylpropylamine

$C_{20}H_{23}N = 277.4$

CAS—50-48-6

A colourless oil, which becomes yellow on standing due to oxidation to a ketonic product.

Amitriptyline Embonate

Proprietary Name. Tryptizol (syrup)

$(C_{20}H_{23}N)_2 \cdot C_{23}H_{16}O_6 = 943.2$

CAS—17086-03-2

A pale yellow to brownish-yellow powder. M.p. about 140°.

Practically *insoluble* in water; soluble 1 in 120 of ethanol, 1 in 6 of acetone, and 1 in 8 of chloroform.

Amitriptyline Hydrochloride

Proprietary Names. Adepril; Amavil; Amiline; Amitid; Amitril; Deprex; Domical; Elavil; Endep; Laroxyl; Lentizol; Levate; Meravil; Novotriptyn; Saroten; Sarotex; Tryptanol; Tryptizol. It is an ingredient of Etrafon, Limbatril, Limbitrol, Triavil, and Triptafen.

Note. Deprex is also used as a proprietary name for dibenzepin hydrochloride.

$C_{20}H_{23}N \cdot HCl = 313.9$

CAS—549-18-8

Colourless crystals or white powder. M.p. 195° to 199°.

Soluble 1 in 1 of water, 1 in 1.5 of ethanol, 1 in 56 of acetone, 1 in 1.2 of chloroform, and 1 in 1 of methanol; practically insoluble in ether.

Dissociation Constant. pK_a 9.4 (25°).

Partition Coefficient. Log *P* (octanol/pH 7.4), 3.0.

Colour Tests. Mandelin's Test—brown → green; Marquis Test—brown-orange; Sulphuric Acid—orange.

Thin-layer Chromatography. *System TA*—Rf 51; *system TB*—Rf 55; *system TC*—Rf 32; *system TL*—Rf 15. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *Marquis reagent*, brown.)

Gas Chromatography. *System GA*—amitriptyline RI 2196, 10-hydroxyamitriptyline RI 2360, 10-hydroxynortriptyline RI 2385, nortriptyline RI 2210; *system GF*—amitriptyline RI 2510, 10-hydroxyamitriptyline RI 2830 or 2880 (stereoisomers).

High Pressure Liquid Chromatography. *System HA*—amitriptyline k' 3.3, 10-hydroxyamitriptyline k' 2.9, 10-hydroxynortriptyline k' 1.8, nortriptyline k' 2.0; *system HF*—amitriptyline k' 5.42, nortriptyline k' 4.58.

Ultraviolet Spectrum. Aqueous acid—239 nm ($A_1^1 = 504$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 756, 770, 746, 969, 1014, 1258 (amitriptyline hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 59, 202, 42, 203, 214, 217, —; 10-hydroxyamitriptyline 58, 42, 69, 41, 30, 215, 202, 59; 10-hydroxynortriptyline 44, 45, 26, 218, 215, 203, 202, 42; nortriptyline 44, 202, 45, 220, 218, 215, 91, —.

Quantification. GAS CHROMATOGRAPHY. In plasma: amitriptyline and nortriptyline, detection limit 10 ng/ml, AFID—S. Dawling and R. A. Braithwaite, *J. Chromat.*, 1978, 146; *Biomed. Appl.*, 3, 449–456.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: amitriptyline and nortriptyline, UV detection—B. Mellström and R. Braithwaite, *J. Chromat.*, 1978, 157, 379–385. In plasma or serum: amitriptyline and nortriptyline, sensitivity 5 ng/ml, UV detection—P. M. Kabra *et al.*, *Clinica chim. Acta*, 1981, 111, 123–132. In urine: amitriptyline and major metabolites, detection limit 100 ng/ml, UV detection—S. R. Biggs *et al.*, *Drug Met. Disp.*, 1979, 7, 233–236.

RADIOIMMUNOASSAY. In serum, saliva, or urine: amitriptyline and nortriptyline, sensitivity 500 pg/ml—G. P. Mould *et al.*, *Ann. clin. Biochem.*, 1978, 15, 221–225.

REVIEW. For a review of analytical methods see B. A. Scoggins *et al.*, *Clin. Chem.*, 1980, 26, 5–17.

Disposition in the Body. Readily absorbed after oral administration and rapidly taken up by the tissues; bioavailability 30 to 60%. The main metabolic reaction is demethylation together with hydroxylation and conjugation with glucuronic acid. The major active metabolite is nortriptyline together with didesmethylnortriptyline and their 10-hydroxy derivatives and conjugates; some amitriptyline *N*-oxide may also be formed. It is mainly excreted in the urine as free and conjugated metabolites, up to about 35% of a single dose being excreted in 24 hours. About 50% of the excreted material is 10-hydroxynortriptyline and its glucuronide conjugate, up to 27% is 10-hydroxyamitriptyline (mainly conjugated); unchanged drug and nortriptyline each account for less than 5% of the excreted material. About 8% of a dose may be eliminated in the faeces as unchanged drug. There appears to be polymorphic variation in the metabolite pattern.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.1 to 0.2 µg/ml (combined amitriptyline and nortriptyline).

After a single oral dose of 50 mg to 3 subjects, peak plasma concentrations for amitriptyline of 0.02 to 0.04 µg/ml (mean 0.025) and for nortriptyline of about 0.01 µg/ml were attained in 2 to 4 hours (W. A. Garland, *J. pharm. Sci.*, 1977, 66, 77–81).

Following daily oral doses of 150 mg to 14 subjects for 3 weeks, steady-state serum concentrations of 0.05 to 0.24 µg/ml (mean 0.13) of amitriptyline, 0.04 to 0.26 µg/ml (mean 0.11) of nortriptyline, 0.05 to 0.25 µg/ml (mean 0.13) of *E*-10-hydroxynortriptyline, and 0.005 to 0.04 µg/ml (mean 0.02) of 10-hydroxyamitriptyline were reported (P. M. Edelbroek *et al.*, *Clin. Pharmac. Ther.*, 1984, 35, 467–473).

TOXICITY. Moderate intoxication is associated with plasma concentrations of 0.05 to 0.17 to 0.43 µg/ml and severe toxic symptoms with concentrations greater than 0.3 µg/ml. The fatal blood concentration range is 0.55 to 3.3 to 16.1 µg/ml. Corresponding toxic doses are greater than 1 g (moderate intoxication) and greater than 2 g (severe or fatal).

In 7 fatalities attributed to amitriptyline overdose, postmortem concentrations, µg/ml or µg/g (mean), were:

	Amitriptyline	Nortriptyline
Blood	0.43–8.30 (3.4)	0.29–6.50 (1.6)
Liver	10.4–243 (92)	4.2–456 (94)

(D. N. Bailey and R. F. Shaw, *J. analyt. Toxicol.*, 1980, 4, 232–236).

In 3 fatalities attributed to amitriptyline overdose, tissue concentrations, µg/ml or µg/g, were:

	Amitriptyline	Nortriptyline
Blood	6, 18, 3	5, —, 2
Liver	72, 66, 58	98, 24, 60
Urine	6, 28, 7	10, 12, 7

(E. C. Munksgaard, *Acta pharmac. Tox.*, 1969, 27, 129–134).

HALF-LIFE. Plasma half-life, 8 to 51 hours (mean 28), increased in overdosage.

DISTRIBUTION IN BLOOD. Plasma : whole blood ratio, 1.2.

SALIVA. Plasma : saliva ratio, 3.

PROTEIN BINDING. In plasma, 91 to 97%.

NOTE. For a review of the pharmacokinetics of tricyclic antidepressants see G. Molnar and R. N. Gupta, *Biopharm. Drug Disp.*, 1980, 1, 283–305.

Dose. 50 to 150 mg of amitriptyline hydrochloride daily; up to 300 mg daily has been given.

Amodiaquine

Antimalarial

Synonym. Amodiachin

Proprietary Name. Basoquin

4-(7-Chloro-4-quinolylamino)-2-(diethylaminomethyl)phenol

$C_{20}H_{22}ClN_3O = 355.9$

CAS—86-42-0

White crystals. M.p. 208°.

Amodiaquine Hydrochloride

Proprietary Names. Camoquin; Flavoquine.

$C_{20}H_{22}ClN_3O \cdot 2HCl \cdot 2H_2O = 464.8$

CAS—69-44-3 (anhydrous); 6398-98-7 (dihydrate)

A yellow crystalline powder. M.p. about 158°.

Soluble 1 in about 22 of water and 1 in about 70 of ethanol; practically insoluble in chloroform and ether.

Colour Tests. Folin–Ciocalteu Reagent—blue; Liebermann's Test—black; Millon's Reagent—orange.

Thin-layer Chromatography. *System TA*—Rf 62; *system TB*—Rf 08; *system TC*—Rf 40. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—not eluted.

Ultraviolet Spectrum. Aqueous acid—237 nm ($A_1^1 = 600$ b), 343 nm; aqueous alkali—273 nm, 287 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1565, 815, 1535, 1255, 869, 847 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 282, 30, 284, 355, 73, 283, 44.

Quantification. SPECTROFLUORIMETRY. In plasma or serum: sensitivity 50 ng/ml—G. M. Trenholme *et al.*, *Bull. Wld Hlth Org.*, 1974, 51, 431–434.

Disposition in the Body. Readily absorbed after oral administration and widely distributed throughout the tissues. After absorption it is slowly released into the blood and excreted in the urine for at least 7 days after a single dose; the rate of excretion is increased in acid urine.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 10 mg/kg to 5 subjects, serum concentrations of 0.30 to 0.68 µg/ml (mean 0.5) were reported after 4 hours; the ratio of erythrocyte to serum concentration varied with time and between individuals, but erythrocyte concentrations were generally higher than serum concentrations after 48 hours (G. M. Trenholme *et al.*, *ibid.*).

Dose. For an acute attack, the equivalent of 1.5 g of amodiaquine in 48 hours (1.2 g in the first 24 hours); for suppression, the equivalent of 300 to 600 mg every 7 days.

Amoxapine

Antidepressant

2-Chloro-11-(piperazin-1-yl)dibenz[*b,f*][1,4]oxazepine

C₁₇H₁₆ClN₃O = 313.8

CAS—14028-44-5

Crystals. M.p. 175° to 176°.

Gas Chromatography. System GA—RI 2659.

Ultraviolet Spectrum. Aqueous acid—252 nm ($A_1^1 = 362$ a), 293 nm ($A_1^1 = 315$ a); aqueous alkali—250 nm, 299 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1604, 1592, 752, 1181, 1246, 1107.

Mass Spectrum. Principal peaks at *m/z* 245, 257, 247, 193, 56, 246, 228, 259.

Quantification. GAS CHROMATOGRAPHY. In serum or urine: amoxapine and metabolites, ECD for serum and FID for urine—T. B. Cooper and R. G. Kelly, *J. pharm. Sci.*, 1979, 68, 216–219.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: amoxapine and 8-hydroxyamoxapine, detection limit 50 ng/ml, UV detection—J. J. Tasset and F. M. Hassan, *Clin. Chem.*, 1982, 28, 2154–2157. In plasma: amoxapine and metabolites, sensitivity 25 ng/ml, UV detection—S. M. Johnson *et al.*, *J. pharm. Sci.*, 1984, 73, 696–699.

Disposition in the Body. Rapidly and almost completely absorbed after oral administration. It is metabolised by hydroxylation to 7-hydroxyamoxapine and 8-hydroxyamoxapine which are both active. The hydroxylated metabolites are excreted in the urine as glucuronide conjugates and are also eliminated in the faeces in unconjugated form. Less than 5% of a dose is excreted in the urine as unchanged drug.

Amoxapine is a metabolite of loxapine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 50 mg to 26 subjects, a mean peak serum-amoxapine concentration of 0.03 µg/ml was attained in 1 to 2 hours; the peak concentration of 8-hydroxyamoxapine was of a similar order (T. B. Cooper and R. G. Kelly, *idem.*).

Following oral administration of 300 mg daily in divided doses to 10 subjects, steady-state serum concentrations of 0.02 to 0.09 µg/ml of amoxapine and 0.16 to 0.51 µg/ml of 8-hydroxyamoxapine were reported (W. E. Boutelle, *Neuropharmacology*, 1980, 19, 1229–1231).

TOXICITY.

The following postmortem concentrations were reported in 3 fatalities due to amoxapine overdose: blood 11.5, 2.8, 0.89 µg/ml, bile 1264.5, 69.1, 14.3 µg/ml, liver 112.2, 40.1, 16.8 µg/g; in the first case brain and urine concentrations of 2.5 µg/g and 28.3 µg/ml, respectively, were also reported (C. L. Winek *et al.*, *Forens. Sci. Int.*, 1984, 26, 33–38).

In a review of 33 cases of amoxapine overdose, 3 subjects had no toxic symptoms, 10 suffered mild toxic reactions, 15 developed severe toxicity, and 5 died. Postmortem blood concentrations of 0.26 to 6.70 µg/ml (mean 2.8) of amoxapine plus 8-hydroxyamoxapine were reported in 4 of the 5 fatalities (T. L. Litovitz and K. G. Troutman, *J. Am. med. Ass.*, 1983, 250, 1069–1071).

The following postmortem tissue concentrations were reported in a fatality due to ingestion of 2 g of amoxapine: blood 7.2 µg/ml, bile 823 µg/ml, liver 36 µg/g; a blood-alcohol concentration of 280 µg/ml was also reported. In a further 2 cases where amoxapine was a contributory cause of death, postmortem concentrations were: blood 1.66 and 2.95 µg/ml, bile 75, – µg/ml, liver –, 23.2 µg/g, urine 22, – µg/ml (N.B. Wu Chen *et al.*, *J. forens. Sci.*, 1983, 28, 116–121).

HALF-LIFE. Plasma half-life, amoxapine about 8 hours, 7-hydroxyamoxapine about 6 hours, 8-hydroxyamoxapine about 30 hours.

PROTEIN BINDING. In plasma, about 90%.

NOTE. For a review of the pharmacokinetics of amoxapine see S. G. Jue *et al.*, *Drugs*, 1982, 24, 1–23.

Dose. 150 to 600 mg daily.

Amoxycillin

Antibiotic

Synonyms. D(–)-α-Amino-*p*-hydroxybenzylpenicillin; Amoxicillin; Amoxicilline.

(6*R*)-6-[α-D-(4-Hydroxyphenyl)glycylamino]penicillanic acid

C₁₆H₁₉N₃O₅S = 365.4

CAS—26787-78-0

Amoxycillin Sodium

Proprietary Names. Amoxil (injection); Clamoxyl (injection).

C₁₆H₁₈N₃NaO₅S = 387.4

CAS—34642-77-8

A white powder.

Soluble 1 in less than 1 of water.

Amoxycillin Trihydrate

Synonym. Amoxicillin

Proprietary Names. Amoxican; Amoxil; Amoxypen; Clamoxyl; Imacillin; Larotid; Moxacin; Moxilean; Novamoxin; Penamox; Polymox; Robamox; Trimox; Utimox; Wymox. It is an ingredient of Augmentin.

C₁₆H₁₉N₃O₅S·3H₂O = 419.4

CAS—61336-70-7

A white crystalline powder.

Soluble 1 in 400 of water, 1 in 1000 of ethanol, and 1 in 200 of methanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 2.4, 7.4, 9.6.

Partition Coefficient. Log *P* (octanol), 0.87.

Ultraviolet Spectrum. Amoxycillin trihydrate: aqueous acid—230 nm ($A_1^1 = 225$ a), 272 nm ($A_1^1 = 26$ a); aqueous alkali—247 nm ($A_1^1 = 286$ b), 291 nm ($A_1^1 = 62$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1775, 1583, 1684, 1248, 1613, 1313 (amoxycillin trihydrate, KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In urine: amoxycillin and penicilloic acid, sensitivity 2.5 µg/ml, fluorescence detection—T. L. Lee, *J. pharm. Sci.*, 1979, 68, 454–458. In plasma: sensitivity 500 ng/ml, UV detection—T. L. Lee and M. A. Brooks, *J. Chromat.*, 1984, 306; *Biomed. Appl.*, 31, 429–435.

Disposition in the Body. Rapidly absorbed after oral administration. About 60% of an oral dose is excreted in the urine as unchanged drug in 6 hours and 20% as the inactive metabolite, penicilloic acid, in the same period. After parenteral administration, up to 75% of a dose is excreted in the urine unchanged in 6 hours.

THERAPEUTIC CONCENTRATION.

Following an oral dose of 500 mg to 8 subjects, peak plasma concentrations of 6.0 to 15.3 µg/ml (mean 10) were attained in 1 to 2 hours (A. Arancibia *et al.*, *Antimicrob. Ag. Chemother.*, 1980, 17, 199–202).

HALF-LIFE. Plasma half-life, about 1 hour, increased in renal failure.

VOLUME OF DISTRIBUTION. About 0.2 to 0.4 litre/kg.

CLEARANCE. Plasma clearance, 3 to 5 ml/min/kg.

PROTEIN BINDING. In plasma, about 20%.

NOTE. For reviews of the pharmacokinetics of amoxycillin see R. N. Brogden *et al.*, *Drugs*, 1975, 9, 88–140 and R. N. Brogden *et al.*, *Drugs*, 1979, 18, 169–184 (amoxycillin injectable).

Dose. The equivalent of 0.75 to 1.5 g of amoxycillin daily. One-day courses of 3 to 6 g are also given.

Amphetamine

Central Stimulant

Synonym. Racemic Desoxynorephedrine

Proprietary Names. It is an ingredient of Biphetamine and Durophet.

(±)-α-Methylphenethylamine

$C_9H_{13}N = 135.2$

CAS—300-62-9

A colourless, mobile, slowly volatile liquid. It absorbs carbon dioxide from the air forming a volatile carbonate. B.p. 200° to 203°.

Soluble 1 in 50 of water; very soluble in ethanol, chloroform, and ether; freely soluble in acids.

Amphetamine Phosphate

Synonyms. Benzpropaminum Phosphoricum; Monobasic Racemic Amphetamine Phosphate.

$C_9H_{13}N, H_3PO_4 = 233.2$

CAS—139-10-6

A white crystalline powder with no characteristic melting-point; it sinters at about 150° and decomposes at about 300°.

Freely **soluble** in water; slightly soluble in ethanol; practically insoluble in chloroform and ether.

Amphetamine Sulphate

Synonyms. Phenaminum; Phenopromini Sulphas; Phenylaminopropanum Racemicum Sulfuricum; Psychedrinum.

Proprietary Name. Benzedrine

$(C_9H_{13}N)_2, H_2SO_4 = 368.5$

CAS—60-13-9

A white crystalline powder. M.p. about 300°, with decomposition.

Soluble 1 in 9 of water and 1 in 515 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 9.9 (20°).

Partition Coefficient. Log P (octanol), 1.8.

Colour Tests. Liebermann's Test—red-orange; Marquis Test—orange → brown; Ninhydrin—pink-orange.

Thin-layer Chromatography. System TA—Rf 43; system TB—Rf 15; system TC—Rf 09. (Dragendorff spray, positive; FPN reagent, pink; acidified iodoplatinate solution, positive; Marquis reagent, brown; ninhydrin spray, positive; acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—RI 1123; system GB—RI 1134; system GC—RI 1536; system GF—RI 1315.

High Pressure Liquid Chromatography. System HA— k' 0.9; system HB— k' 8.48; system HC— k' 0.98.

Ultraviolet Spectrum. Aqueous acid—251 nm, 257 nm ($A_1^1 = 14$ a), 263 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 700, 740, 1495, 1090, 1605, 825 (thin film). (See below)

Mass Spectrum. Principal peaks at m/z 44, 91, 40, 42, 65, 45, 39, 43; phenylacetone 43, 91, 134, 92, 65, 39, 63, 135.

Quantification. GAS CHROMATOGRAPHY. In urine: amphetamine and methylamphetamine, detection limit 10 ng/ml, ECD—M. Terada *et al.*, *J. Chromat.*, 1982, 237, 285–292.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma or cerebrospinal fluid—N. Narasimhachari *et al.*, *J. Chromat.*, 1979, 164; *Biomed. Appl.*, 6, 386–393.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: sensitivity 20 ng/ml and 4 ng/ml, respectively, UV detection—B. M. Farrell and T. M. Jeffries, *J. Chromat.*, 1983, 272; *Biomed. Appl.*, 23, 111–128.

Disposition in the Body. Readily absorbed after oral or rectal administration; rapidly distributed extravascularly and taken up, to some extent, by red blood cells. The main metabolic

reaction is oxidative deamination to form phenylacetone, which is then oxidised to benzoic acid and conjugated with glycine to form hippuric acid; minor reactions include aromatic hydroxylation to form 4-hydroxyamphetamine (an active metabolite), β -hydroxylation which is stereoselective for the (+)-isomer of amphetamine, to form norephedrine (phenylpropanolamine), and *N*-oxidation to form a hydroxylamine derivative. The products of aromatic hydroxylation and *N*-oxidation may be conjugated with sulphate or glucuronic acid.

Excretion of amphetamine is markedly dependent on urinary pH, being greatly increased in acid urine. After large doses, amphetamine may be detected in urine for several days. Under uncontrolled urinary pH conditions, about 30% of the dose is excreted unchanged in the urine in 24 hours and a total of about 90% of the dose is excreted in 3 to 4 days. The amount excreted unchanged in 24 hours may increase to 74% of the dose in acid urine and decrease to 1 to 4% in alkaline urine; under alkaline conditions, hippuric acid and benzoic acid account for about 50% of the urinary material. Under normal conditions 16 to 28% is excreted as hippuric acid, about 4% as benzoylglucuronide, 2 to 4% as 4-hydroxyamphetamine and about 2% as norephedrine in 24 hours; small amounts of conjugated 4-hydroxynorephedrine and phenylacetone are also excreted. No elimination in the faeces has been detected.

Amphetamine is a metabolite of benzphetamine, methylamphetamine, and selegiline.

THERAPEUTIC CONCENTRATION. After normal therapeutic doses the plasma concentration is usually below 0.1 $\mu\text{g/ml}$. However, continued use of amphetamine may cause addiction, and ingestion of 10 times the usual therapeutic dose is common among addicts; in such cases the plasma concentration may be up to 3 $\mu\text{g/ml}$.

After a single oral dose containing 10 mg of amphetamine to 4 subjects, peak plasma concentrations of about 0.02 $\mu\text{g/ml}$ were attained (S. H. Wan *et al.*, *Clin. Pharmac. Ther.*, 1978, 23, 585–590).

Steady-state blood concentrations of 2 to 3 $\mu\text{g/ml}$ were observed in a regular user who ingested about 1 g a day (R. H. Cravey and N. C. Jain, *Trauma*, 1973, 15, 49–94).

The intravenous administration of 160 mg of amphetamine to a regular user resulted in a plasma concentration of 0.59 $\mu\text{g/ml}$ after 1 hour (E. Anggard *et al.*, *Scand J. clin. Lab. Invest.*, 1970, 26, 137–143).

TOXICITY. The estimated minimum lethal dose in non-addicted adults is 200 mg. Toxic effects may be produced with blood concentrations of 0.2 to 3 $\mu\text{g/ml}$, and fatalities with concentrations greater than 0.5 $\mu\text{g/ml}$. Deaths from overdosage are comparatively rare.

The following postmortem tissue concentrations were reported in 3 fatalities due to amphetamine (route of administration intravenous in cases 1 and 3, unknown in case 2): blood 0.5, 6, 7 $\mu\text{g/ml}$, kidney 4, –, 8 $\mu\text{g/g}$, liver 45, 35, 12 $\mu\text{g/g}$, urine –, 700, – $\mu\text{g/ml}$ (S. Orrenius and A. C. Maehly, *Z. Rechtsmed.*, 1970, 67, 184–189).

In a fatality due to intravenous administration of amphetamine, the following postmortem tissue concentrations were reported: blood 41 $\mu\text{g/ml}$, liver 23 $\mu\text{g/g}$, urine 39 $\mu\text{g/ml}$ (G. Adjutantis *et al.*, *Medicine, Sci. Law*, 1975, 15, 62–63).

Urine concentrations of <0.5 to 320 $\mu\text{g/ml}$ (mean 76) were reported in 11 fatalities due to amphetamine (P. Holmgren and O. Lindquist, *Z. Rechtsmed.*, 1975, 75, 265–273).

HALF-LIFE. Plasma half-life, 4 to 8 hours when the urine is acidic and about 12 hours in subjects whose urinary pH values are uncontrolled.

VOLUME OF DISTRIBUTION. About 3 to 4 litres/kg.

SALIVA. Plasma : saliva ratio, about 0.35.

PROTEIN BINDING. In plasma, 15 to 40%.

Dose. 20 to 100 mg of amphetamine sulphate daily.

Amphotericin

Antifungal

Synonyms. Amphotericin B; Anfotericina B.

Proprietary Names. Ampho-Moronal; Fungilin; Fungizone. It is an ingredient of Mystecilin (syrup).

A mixture of antifungal polyenes produced by the growth of certain strains of *Streptomyces nodosus* or by any other means.

$\text{C}_{47}\text{H}_{73}\text{NO}_{17}$ = 924.1

CAS—1397-89-3

A yellow to orange powder. It gradually decomposes above 170°. Practically **insoluble** in water, ethanol, chloroform, and ether; soluble 1 in 200 of dimethylformamide and 1 in 20 of dimethyl sulphoxide; soluble in propylene glycol.

Dissociation Constant. pK_a 5.5, 10.0.

Infra-red Spectrum. Principal peaks at wavenumbers 1010, 1065, 1038, 1103, 1183, 1126 (KBr disk).

Quantification. **HIGH PRESSURE LIQUID CHROMATOGRAPHY.** In serum or cerebrospinal fluid: sensitivity 20 ng/ml, UV detection—I. Nilsson-Ehle *et al.*, *J. infect. Dis.*, 1977, 135, 414–422.

Disposition in the Body. Poorly absorbed after oral, intramuscular, or subcutaneous administration. It is slowly excreted in the urine, less than 10% of a dose being excreted unchanged in 24 hours; up to 40% of a dose is excreted in the urine in 7 days and traces are still detectable in urine 2 months after cessation of treatment.

THERAPEUTIC CONCENTRATION.

A mean serum concentration of 1.2 $\mu\text{g/ml}$ was reported in 20 subjects 1 hour after an intravenous infusion of 50 mg (B. T. Fields *et al.*, *Appl. Microbiol.*, 1970, 19, 955–959).

HALF-LIFE. Plasma half-life, about 24 to 48 hours; a longer terminal elimination phase of about 15 days has also been reported.

VOLUME OF DISTRIBUTION. About 4 litres/kg.

CLEARANCE. Plasma clearance, about 0.4 ml/min/kg.

PROTEIN BINDING. In plasma, 90 to 97%.

NOTE. For a review of amphotericin see T. K. Daneshead and D. W. Warnock, *Clin. Pharmacokinet.*, 1983, 8, 19-23.

Dose. Up to 800 mg daily by mouth. Doses of 0.25 to 1 mg/kg daily are given intravenously.

Ampicillin

Antibiotic

Synonyms. Aminobenzylpenicillin; Anhydrous Ampicillin.

Proprietary Names of Ampicillin, Ampicillin Sodium and Ampicillin Trihydrate. A-Cillin; Alpen; Amblosin; Amcill; Amfipen; Amperil; Ampilar; Ampilean; Binotal; Biosan; Britcin; D-Amp; Omnipen; Pen A; Penbritin(e); Pensyn; Pentrexyl; Polycillin; Principen; Robamox; Supen; Totacillin; Vidopen.

(6R)-6-(α -D-Phenylglycylamino)penicillanic acid

$C_{16}H_{19}N_3O_4S = 349.4$

CAS—69-53-4

A white crystalline powder. M.p. about 200°.

Soluble 1 in 170 of water; practically insoluble in ethanol, acetone, carbon tetrachloride, chloroform, and ether.

Ampicillin Sodium

$C_{16}H_{18}N_3NaO_4S = 371.4$

CAS—69-52-3

A white, hygroscopic, crystalline or amorphous powder. Aqueous solutions containing 10% or more deteriorate rapidly on storage. M.p. about 205°, with decomposition.

Soluble 1 in 2 of water and 1 in 50 of acetone; slightly soluble in chloroform; practically insoluble in ether. With ethanol, ampicillin sodium forms a colloidal dispersion which gels on standing.

Ampicillin Trihydrate

$C_{16}H_{19}N_3O_4S \cdot 3H_2O = 403.4$

CAS—7177-48-2

A white crystalline powder.

Soluble 1 in 150 of water; practically insoluble in ethanol, acetone, carbon tetrachloride, chloroform, and ether.

Dissociation Constant. pK_a 2.5 (—COOH), 7.3 (—NH₂), (25°).

Colour Tests. Liebermann's Test—orange.

Suspend 10 mg in 1 ml of water and add 2 ml of a mixture of 2 ml of potassium cupri-tartrate solution and 6 ml of water—red-violet.

Ultraviolet Spectrum. Aqueous acid—257 nm ($A_1^1 = 9.2$ a), 262 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1775, 1693, 1526, 1308, 1497, 1583 (KBr disk).

Quantification. SPECTROFLUORIMETRY. In serum: sensitivity 50 ng/ml—H. J. H. Keshavan *et al.*, *Clin. Chem.*, 1979, 25, 1674-1675.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma, saliva or urine: sensitivity 500 ng/ml, UV detection—T. B. Vree *et al.*, *J. Chromat.*, 1978, 145; *Biomed. Appl.*, 2, 496-501.

POLAROGRAPHY. In serum or urine—S. Schroeder *et al.*, *Pharmazie*, 1978, 33, 432-434.

Disposition in the Body. Readily but incompletely absorbed after oral administration. About 30% of an oral dose is excreted in the

urine in 6 hours as unchanged drug and about 10% as penicilloic acid; after parenteral administration about 75% is excreted unchanged in 6 hours. High concentrations of ampicillin are attained in the bile.

THERAPEUTIC CONCENTRATION.

After an oral dose of 500 mg given to 6 young subjects, peak plasma concentrations of 2.65 to 4.0 μ g/ml (mean 3.4) were attained in about 2 hours; higher concentrations were reported when a similar dose was given to 6 elderly subjects (E. J. Triggs *et al.*, *Eur. J. clin. Pharmac.*, 1980, 18, 195-198).

HALF-LIFE. Plasma half-life, about 1 to 2 hours.

VOLUME OF DISTRIBUTION. About 0.2 to 0.5 litre/kg.

CLEARANCE. Plasma clearance, about 3 to 4 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, 1.8.

PROTEIN BINDING. In plasma, about 20%.

NOTE. For a review of the pharmacokinetics of penicillins see M. Barza and L. Weinstein, *Clin. Pharmacokinet.*, 1976, 1, 297-308.

Dose. 1 to 8 g daily.

Amprolium Hydrochloride

Coccidiostat (Veterinary)

Proprietary Names. It is an ingredient of Amprolmix-UK, Amprol-Plus, Pancoxin, and Supacox.

1-(4-Amino-2-propylpyrimidin-5-ylmethyl)-2-methylpyridiniumchloride hydrochloride

$C_{14}H_{19}ClN_4 \cdot HCl = 315.2$

CAS—121-25-5 (amprolium); 137-88-2 (hydrochloride)

A white powder. M.p. 247°, with decomposition.

Soluble 1 in 2 of water and 1 in 170 of ethanol; practically insoluble in chloroform; very slightly soluble in ether.

Colour Test. Aromaticity (Method 2)—colourless/yellow.

Thin-layer Chromatography. System TA—Rf 02. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—246 nm ($A_1^1 = 420$ b), 262 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1638, 1522, 1593, 787, 1562, 1149 (amprolium, KBr disk).

Amygdalin

Synonym. Amygdalose

Note. The name 'laetrile' is frequently used to describe amygdalin but it has also been used to describe *l*-mandelonitrile- β -glucuronide, a substance which may be derived from amygdalin. *O*-(6-*O*- β -D-Glucopyranosyl- β -D-glucopyranosyl)-D-mandelonitrile

$C_{20}H_{27}NO_{11} = 457.4$

CAS—29883-15-6

A colourless, crystalline, cyanogenic, glycoside present in bitter almond seeds, *Prunus amygdalus* var. *amara*, apricot kernels and other seeds of the Rosaceae. M.p. about 220°; after solidifying the substance remelts at 125° to 130°.

Soluble 1 in 12 of water and 1 in 900 of ethanol; practically insoluble in ether.

Infra-red Spectrum. Principal peaks at wavenumbers 1065, 1025, 695, 758, 1272, 890 (KCl disk).

Mass Spectrum. Principal peaks at m/z 43, 31, 57, 73, 60, 29, 55, 44.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 2 μ g/ml, FID—J. F. Stobaugh, *Analyt. Lett. (Part B)*, 1978, 11, 753–764.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: amygdalin and prunasin, sensitivity 1 μ g/ml, UV detection—A. G. Rauws *et al.*, *Pharm. Weekbl. (Sci. Edn)*, 1982, 4, 172–175.

Disposition in the Body. Poorly absorbed after ingestion and slowly hydrolysed in the gastro-intestinal tract to mandelonitrile- β -glucoside (prunasin), mandelonitrile, and glucose, and finally to benzaldehyde and hydrogen cyanide. After ingestion, about 8 to 32% of a dose is excreted unchanged in the urine; after parenteral administration, only small amounts are hydrolysed and most of a dose is excreted unchanged in the urine. Urinary cyanide and thiocyanate concentrations are not significantly elevated after oral or intravenous administration.

BLOOD CONCENTRATION.

In 6 subjects ingesting 500 mg of amygdalin three times a day, peak plasma concentrations of <1 μ g/ml of amygdalin were attained in 30 to 60 minutes; peak plasma-cyanide concentrations of 0.4 to 2.1 μ g/ml (mean 1.0) were reported 1.5 to 2 hours after a dose on the second day; plasma-thiocyanate concentrations accumulated on repeated administration of amygdalin to about 25 μ g/ml on the last day of ingestion (C. G. Moertel *et al.*, *J. Am. med. Ass.*, 1981, 245, 591–594).

Following an intramuscular injection of 6 g to 1 subject, a peak plasma concentration of 180 μ g/ml was attained in 1.25 hours (M. M. Ames *et al.*, *Res. Commun. chem. Path. Pharmac.*, 1978, 22, 175–185).

TOXICITY. Several reports of cyanide poisoning following administration of amygdalin have been recorded, mostly involving the ingestion of apricot or other fruit kernels. Cyanide release from amygdalin is known to occur in the presence of β -glucosidase enzymes which are present in some raw fruits and vegetables. Toxic effects or fatalities have been associated with blood-cyanide concentrations greater than 2 μ g/ml.

A blood-cyanide concentration of 10 μ g/ml was reported in one subject with toxic effects following daily ingestion of 1500 mg of amygdalin (F. P. Smith *et al.*, *J. Am. med. Ass.*, 1977, 238, 1361).

In a fatality involving amygdalin ingestion, a postmortem blood-cyanide concentration of 2.18 μ g/ml was reported (S. N. Vogel *et al.*, *Clin. Toxicol.*, 1981, 18, 367–383).

NOTE. For a review of the literature on amygdalin see R. F. Chandler *et al.*, *Pharm. J.*, 1984, 232, 330–332.

Amyl Acetate

Solvent

A mixture of isomers, principally isoamyl acetate (3-methylbutyl acetate), *sec*-amyl acetate (2-methylbutyl acetate), and *n*-amyl acetate.

$C_7H_{14}O_2 = 130.2$

CAS—123-92-2 (iso); 53496-15-4 (*sec*); 628-63-7 (*n*)

A colourless, mobile, inflammable liquid. B.p. about 140°.

Refractive index 1.400.

Slightly **soluble** in water; miscible with ethanol and ether.

Mass Spectrum. Principal peaks at m/z 43, 70, 55, 42, 41, 73, 61, 87.

Disposition in the Body.

TOXICITY. The estimated minimum lethal dose is 50 g and the maximum permissible atmospheric concentration is 100 ppm for iso- or *n*-amyl acetate and 125 ppm for *sec*-amyl acetate.

Amyl Alcohol

Solvent

Synonym. Amylic Alcohol

A mixture of mainly 3-methylbutan-1-ol (primary isoamyl alcohol) [(CH₃)₂CH·CH₂·CH₂OH] with some 2-methylbutan-1-ol (primary amyl alcohol) [CH₃·CH₂·CH(CH₃)·CH₂OH].

$C_5H_{12}O = 88.15$

CAS—123-51-3 (3-methylbutan-1-ol); 137-32-6 (2-methylbutan-1-ol)

A colourless liquid obtained by purifying fusel oil. B.p. 128° to 132°. Refractive index 1.4075.

Slightly **soluble** in water; miscible with ethanol, chloroform, and ether.

Mass Spectrum. Principal peaks at m/z 55, 41, 42, 43, 70, 57, 29, 31.

Disposition in the Body.

TOXICITY. It is toxic after ingestion. The estimated minimum lethal dose is 30 g and the maximum permissible atmospheric concentration is 100 ppm.

Amyl Nitrite

Anti-anginal Vasodilator

Synonyms. Isoamyl Nitrite; Isopentyl Nitrite.

It consists of the nitrites of 3-methylbutan-1-ol $[(CH_3)_2CH \cdot CH_2 \cdot CH_2OH]$ and 2-methylbutan-1-ol $[CH_3 \cdot CH_2 \cdot CH(CH_3) \cdot CH_2OH]$, with other nitrites of the homologous series.

$C_5H_{11}NO_2 = 117.1$

CAS—8017-89-8; 110-46-3

A clear, yellow, volatile, inflammable liquid, with a fragrant odour. Incompatible with ethanol. Store in a cool place in airtight containers; protect from light. Wt per ml 0.868 to 0.878 g. B.p. 96°. Refractive index 1.3871.

Practically **insoluble** in water; miscible with ethanol, chloroform, and ether.

Caution. Amyl nitrite forms an explosive mixture with air or oxygen. It is very inflammable and must not be used where it may be ignited.

Colour Tests. To 0.2 ml add 2 ml of a 2% ferrous sulphate solution and 5 ml of *dilute hydrochloric acid*—green-brown; to 0.2 ml add 0.5 ml of aniline and 5 ml of *acetic acid*—orange-red.

Gas Chromatography. *System GA*—RI 680; *system GI*—retention time 20.3 min.

Mass Spectrum. Principal peaks at m/z 70, 43, 55, 41, 57, 42, 71, —.

Disposition in the Body. Absorbed from the mucous membranes after inhalation but rapidly inactivated by hydrolysis. Inactive after ingestion due to hydrolysis in the gastro-intestinal tract.

TOXICITY. Recovery has occurred after the ingestion of 12 ml.

Dose. 0.12 to 0.3 ml, by inhalation.

Amylmetacresol

Antiseptic

Synonym. 6-Pentyl-*m*-cresol

Proprietary Name. It is an ingredient of Strepsils.

5-Methyl-2-pentylphenol

$C_{12}H_{18}O = 178.3$

CAS—1300-94-3

A colourless or slightly yellow, clear liquid or solid crystalline mass, which darkens on keeping. M.p. 24°.

Practically **insoluble** in water; soluble in ethanol and ether.

Ultraviolet Spectrum. Acidified dehydrated alcohol—278 nm ($A_1^1 = 132$ a), 286 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1120, 1225, 1272, 805, 1584, 938 (thin film).

Amylobarbitone

Barbiturate

Synonyms. Amobarbital; Pentymalum.

Proprietary Names. Amal; Amylbarb; Amytal; Etamyl; Eunoc-tal; Neur-Amyl; Stadadorm. It is an ingredient of Dexamyl.

5-Ethyl-5-isopentylbarbituric acid

$C_{11}H_{18}N_2O_3 = 226.3$

CAS—57-43-2

A white crystalline powder. M.p. 155° to 161°.

Soluble 1 in 1500 of water, 1 in 5 of ethanol, 1 in 20 of chloroform, and 1 in 6 of ether; soluble in aqueous solutions of alkali hydroxides and carbonates.

Amylobarbitone Sodium

Synonyms. Amobarbital Sodium; Barbamylum; Soluble Amylobarbitone. **Proprietary Names.** Amylbarb Sodium; Amylobeta; Neur-Amyl Sodium; Sodium Amytal. It is an ingredient of Tuinal.

$C_{11}H_{17}N_2NaO_3 = 248.3$

CAS—64-43-7

A white, hygroscopic, granular powder. M.p. about 156°.

Soluble 1 in less than 1 of water and 1 in 2 of ethanol; practically insoluble in chloroform and ether. Solutions in water decompose on standing.

Dissociation Constant. pK_a 7.9 (25°).

Partition Coefficient. Log P (octanol/pH 7.4), 1.6.

Colour Tests. Koppanyi-Zwicker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. *System TD*— R_f 52; *system TE*— R_f 36; *system TF*— R_f 65; *system TH*— R_f 74. (*Mercuric chloride-diphenylcarbazone reagent*, positive; *mercurous nitrate spray*, black; *Zwicker's reagent*, pink.)

Gas Chromatography. *System GA*—amylobarbitone RI 1718, 3'-hydroxyamylobarbitone RI 1632; *system GF*—RI 2430.

High Pressure Liquid Chromatography. *System HG*— k' 10.91; *system HH*— k' 7.05.

Ultraviolet Spectrum. *Borax buffer 0.05M* (pH 9.2)—240 nm ($A_1^1 = 445$ a); *M sodium hydroxide* (pH 13)—255 nm ($A_1^1 = 364$ b). (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1725, 1696, 1758, 1317, 1240, 850 (KBr disk) (See below).

Mass Spectrum. Principal peaks at m/z 156, 141, 157, 41, 55, 142, 98, 39; 3'-hydroxyamylobarbitone 59, 157, 156, 141, 43, 41, 71, 69.

Quantification. The following are general methods for most barbiturates.

GAS CHROMATOGRAPHY. In plasma or urine: detection limit < 500 pg/ml, AFID—T. Villén and I. Petters, *J. Chromat.*, 1983, 258, 267–270. In plasma: sensitivity < 500 ng/ml, AFID—A. Turcant *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 222–

226. For a review of gas chromatographic methods see D. N. Pillai and S. Dilli, *J. Chromat.*, 1981, 220; *Chromatogr. Rev.*, 25, 253–274.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In blood: detection limit < 1 µg/ml, UV detection—R. Gill *et al.*, *J. Chromat.*, 1981, 226; *Biomed. Appl.*, 25, 117–123.

IMMUNOASSAY. In urine: barbiturates and metabolites, sensitivity 2 µg/ml for quinalbarbitone using EMIT and 10 ng/ml using RIA—B. Law and A. C. Moffat, *J. forens. Sci. Soc.*, 1981, 21, 55–66.

Disposition in the Body. Readily and almost completely absorbed after oral administration; bioavailability about 95%. It is metabolised by hydroxylation to give the major metabolite 3'-hydroxyamylobarbitone, which has about one-third of the

activity of the parent substance. About 80 to 90% of a dose is excreted in the urine in 6 days, of which 30 to 50% is 3'-hydroxyamylobarbitone, up to 30% is *N*-β-D-glucopyranosylamylobarbitone, and about 1% is unchanged drug. The metabolite pattern appears to be genetically determined. 5-(3'-Carboxybutyl)-5-ethylbarbituric acid has also been identified as a metabolite in urine. About 5% of a dose is eliminated in the faeces in 6 days.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 2 to 12 µg/ml.

TOXICITY. The estimated minimum lethal dose is 1.5 g. Toxic effects are associated with plasma concentrations greater than 9 µg/ml and fatalities with postmortem blood concentrations of 9 to 26 to 72 µg/ml.

In a review of 55 cases of fatal overdose, postmortem blood concentrations were in the range 13 to 96 µg/ml (R. C. Gupta and J. Kofoed, *Can. med. Ass. J.*, 1966, 94, 863–865).

In 3 fatalities attributed to amylobarbitone overdose, the following postmortem tissue concentrations, µg/ml or µg/g, were reported:

	Amylo-barbitone	3'-Hydroxyamylo-barbitone
Blood	36, 35, 25	2, —, 2
Bile	198, 178, —	6, —, —
Kidney	32, 59, 87	—, 2, 4
Liver	71, 79, 224	1, 2, 2
Lung	43, 40, 84	—, 2, 4
Spleen	77, 63, 104	—, 1, —
Urine	12, 12, —	9, —, —

(A. E. Robinson and R. D. McDowall, *J. Pharm. Pharmacol.*, 1979, 31, 357–365).

HALF-LIFE. Plasma half-life, 8 to 40 hours (mean 24).

VOLUME OF DISTRIBUTION. About 1 litre/kg.

CLEARANCE. Plasma clearance, about 0.5 ml/min/kg.

SALIVA. Plasma: saliva ratio, about 2.8.

PROTEIN BINDING. In plasma, 40 to 60%.

NOTE. For a review of the clinical pharmacokinetics of barbiturates see D. D. Breimer, *Clin. Pharmacokinet.*, 1977, 2, 93–109.

Dose. 30 to 240 mg daily; up to 600 mg daily has been given.

Androsterone

Androgen

3α-Hydroxy-5α-androstan-17-one

C₁₉H₃₀O₂ = 290.4

CAS—53-41-8

A white crystalline powder. M.p. about 185°.

Practically **insoluble** in water; soluble in ethanol, ether, and in most organic solvents.

Colour Tests. Antimony Pentachloride—yellow → brown; Naphthol-Sulphuric Acid—orange-brown/orange; Sulphuric Acid—yellow.

Gas Chromatography. System GA—RI 2488.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1724, 1000, 1031, 1062, 1242, 1282 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 290, 67, 108, 107, 79, 55, 41, 93.

Disposition in the Body. Androsterone is a naturally occurring androgen which may be isolated from male urine. It is a major metabolite of testosterone.

Anileridine

Narcotic Analgesic

Ethyl 1-(4-aminophenethyl)-4-phenylpiperidine-4-carboxylate

$C_{22}H_{28}N_2O_2 = 352.5$

CAS—144-14-9

A white to yellowish-white crystalline powder. When exposed to light and air it oxidises and darkens in colour. There are 2 crystalline forms which melt at about 80° and about 89°.

Very slightly **soluble** in water; soluble 1 in 2 of ethanol and 1 in 1 of chloroform; soluble in ether but solutions may be turbid.

Anileridine Hydrochloride

Proprietary Name. Leritine (tablets)

$C_{22}H_{28}N_2O_2 \cdot 2HCl = 425.4$

CAS—126-12-5

A white crystalline powder. M.p. about 270°, with decomposition.

Soluble 1 in 5 of water and 1 in 80 of ethanol; practically insoluble in chloroform and ether.

Anileridine Phosphate

Proprietary Name. Leritine (injection)

$C_{22}H_{28}N_2O_2 \cdot H_3PO_4 = 450.5$

CAS—4268-37-5

A white crystalline powder.

Very **soluble** in water. Solutions are unstable above pH 4.

Dissociation Constant. pK_a 3.7, 7.5.

Colour Tests. Diazotisation—red; Marquis Test—orange (slow).

Thin-layer Chromatography. *System TA*— R_f 73. (*Acidified iodoplatinate solution*, positive).

Gas Chromatography. *System GA*— R_I 2850; *system GC*— R_I 3469.

High Pressure Liquid Chromatography. *System HA*— k' 1.1.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm, 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1700, 1120, 1179, 1512, 1219, 1620 (KCl disk).

Mass Spectrum. Principal peaks at m/z 246, 247, 42, 120, 218, 172, 106, 91.

Disposition in the Body. Readily absorbed after oral administration. Metabolised by hydrolysis to anileridinic acid followed by acetylation to acetylanileridinic acid; conjugation with acetic

acid followed by partial de-esterification to acetylanileridinic acid also occurs. After oral administration, 5% of the dose is excreted in the urine as unchanged drug, with 7 to 14% as free anileridinic acid, 1 to 2% as acetylanileridinic acid, 0.5 to 2% as acetylanileridine, and 15 to 35% as diazotisable metabolites, tentatively identified as *p*-acetylamino phenylacetic acid; norpethidine has also been detected in urine.

TOXICITY. The estimated minimum lethal dose is 0.5 g but it may be up to 5 g in addicts.

The following postmortem concentrations were reported in a fatality attributed to oral overdosage of anileridine: blood 0.9 µg/ml, bile 2.4 µg/ml, urine 11.4 µg/ml, vitreous humour 0.07 µg/ml; diazepam was also detected (M. A. Peat and L. Kopjak, *Bull. int. Ass. forens. Toxicol.*, 1979, 14(3), 19).

Dose. Up to the equivalent of 200 mg of anileridine daily.

Aniline*Synonym.* Phenylamine $C_6H_5 \cdot NH_2 = 93.13$

CAS—62-53-3

A colourless or pale yellow, oily liquid, with a characteristic odour. It readily darkens to brown on exposure to air and light. F.p. -6° . B.p. about 183° . Refractive index 1.5863.

Soluble 1 in 30 of water; miscible with ethanol, chloroform, and ether.

Dissociation Constant. pK_a 4.6 (25°).

Partition Coefficient. Log P (octanol), 0.9.

Colour Tests. Coniferyl Alcohol—orange; Diazotisation—red; Liebermann's Test—red-orange; Potassium Dichromate—blue-green (2 min).

Thin-layer Chromatography. System TA—Rf 72. (Acidified potassium permanganate solution, positive; Van Urk reagent, bright yellow.)

Gas Chromatography. System GA—aniline RI 1158, 4-aminophenol RI 1265.

Ultraviolet Spectrum. Aqueous acid—249 nm ($A_1^1 = 13$ b), 255 nm ($A_1^1 = 16$ b), 261 nm ($A_1^1 = 12.5$ b); ethanol—235 nm ($A_1^1 = 1007$ b), 286 nm ($A_1^1 = 179$ b).

Mass Spectrum. 4-Aminophenol: principal peaks at m/z 109, 80, 53, 81, 108, 52, 54, 110.

Quantification. GAS CHROMATOGRAPHY. In postmortem tissues: AFID—J. S. Oliver and D. J. Williams, *Bull. int. Ass. forens. Toxicol.*, 1974, 10(2), 6–7.

Disposition in the Body. Readily absorbed from the skin and mucous membranes. Metabolised to 4-aminophenol and 4-acetamidophenol which are excreted in the urine as glucuronide and sulphate conjugates. *N*-Phenylsulphamic acid (aniline *N*-sulphate) is also a metabolite. The main toxic effect of aniline, the formation of methaemoglobin, is thought to be due to an oxidation product of aniline, phenylhydroxylamine.

Aniline is a metabolite of phenazopyridine.

TOXICITY. The minimum lethal dose may be as low as 1 g although recovery has followed the ingestion of 30 g. Serious toxic effects may occur after exposure for about 1 hour to atmospheric concentrations of 100 to 160 ppm. The maximum permissible atmospheric concentration is 2 ppm. Urinary concentrations of greater than 10 $\mu\text{g/ml}$ of 4-aminophenol may indicate toxic exposure to aniline.

The following postmortem tissue concentrations were reported in a fatality attributed to ingestion of an aniline-based ink: blood 6.3 $\mu\text{g/ml}$, liver 20 $\mu\text{g/g}$, urine 40 $\mu\text{g/ml}$ (J. S. Oliver and D. J. Williams, *ibid.*).

Anisindione*Anticoagulant**Proprietary Names.* Miradon; Unidone.

2-(4-Methoxyphenyl)indan-1,3-dione

 $C_{16}H_{12}O_3 = 252.3$

CAS—117-37-3

A white or creamy-white powder. M.p. 152° to 158° .

Practically **insoluble** in water; soluble in ether and methanol.

Dissociation Constant. pK_a 4.1.

Gas Chromatography. System GA—RI 2273.

Ultraviolet Spectrum. Aqueous acid—273 nm; ethanol—286 nm ($A_1^1 = 1400$ b), 340 nm.

Mass Spectrum. Principal peaks at m/z 252, 237, 253, 181, 238, 77, 76, 209.

Dose. Maintenance, 25 to 250 mg daily.

Antazoline*Antihistamine**Synonyms.* Imidamin; Phenazoline.*N*-Benzyl-*N*-(2-imidazolin-2-ylmethyl)aniline $C_{17}H_{19}N_3 = 265.4$

CAS—91-75-8

Crystals. M.p. about 121° .

Antazoline Hydrochloride*Synonym.* Phenazolinum*Proprietary Name.* Antistin(e) (tablets) $C_{17}H_{19}N_3 \cdot HCl = 301.8$

CAS—2508-72-7

A white crystalline powder. M.p. about 240° , with decomposition.

Soluble 1 in 50 of water and 1 in 16 of ethanol; slightly soluble in chloroform; practically insoluble in ether.

Antazoline Mesylate*Synonym.* Antazoline Methanesulphonate*Proprietary Name.* Antistin (injection) $C_{17}H_{19}N_3 \cdot CH_3SO_3H = 361.5$

CAS—3131-32-6

A white, slightly hygroscopic powder. M.p. 165° to 168° .

Soluble 1 in 6 of water, 1 in 7 of ethanol, and 1 in 12 of chloroform; practically insoluble in ether.

Antazoline Phosphate

Proprietary Name. It is an ingredient of Vasocon A.

$C_{17}H_{19}N_3 \cdot H_3PO_4 = 363.4$

CAS—154-68-7

A white crystalline powder. M.p. 194° to 198°, with decomposition.

Soluble in water; sparingly soluble in methanol; practically insoluble in ether.

Dissociation Constant. pK_a 2.5, 10.1 (25°).

Colour Tests. Liebermann's Test—red; Mandelin's Test—red-violet.

Thin-layer Chromatography. *System TA*—Rf 31; *system TB*—Rf 07; *system TC*—Rf 07. (*Dragendorff spray*, positive; *FPN reagent*, pink; *acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2328; *system GC*—RI 2749.

High Pressure Liquid Chromatography. *System HA*— k' 1.8.

Ultraviolet Spectrum. Aqueous acid—241 nm ($A_1^1 = 578$ a), 291 nm; aqueous alkali—247 nm, 295 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1164, 1599, 1042, 1508, 750, 700 (antazoline mesylate, KBr disk).

Mass Spectrum. Principal peaks at m/z 84, 91, 77, 55, 182, 85, 65, 104.

Quantification. COLORIMETRY. In urine—N. Wahba *et al.*, *Pharmazie*, 1974, 29, 790–791.

Disposition in the Body. Readily absorbed after oral or parenteral administration. About 2% of an oral dose is excreted unchanged in the urine in 24 hours.

Dose. Antazoline hydrochloride has been given in doses of 100 to 600 mg daily.

Apomorphine

Emetic

(6aR) - 5,6,6a,7 - Tetrahydro - 6 - methyl - 4H - dibenzo[de,g]quinoline-10,11-diol

$C_{17}H_{17}NO_2 = 267.3$

CAS—58-00-4

Crystals. M.p. about 195°, with decomposition. The crystals and aqueous solutions oxidise rapidly in light and air, turning green. Slightly **soluble** in water and ether; soluble in ethanol and chloroform.

Apomorphine Hydrochloride

$C_{17}H_{17}NO_2 \cdot HCl \cdot \frac{1}{2}H_2O = 312.8$

CAS—314-19-2 (anhydrous); *41372-20-7* (hemihydrate)

White or greyish-white glistening crystals or microcrystalline powder. Decomposes between 225° and 236°.

Soluble 1 in 50 of water and 1 in 20 of water at 80°; soluble 1 in 50 of ethanol; very slightly soluble in chloroform and ether.

Dissociation Constant. pK_a 7.2, 8.9 (15°).

Colour Tests. Ferric Chloride—blue; Liebermann's Test—black; Marquis Test—violet → black; Methanolic Potassium Hydroxide—green → red; Nessler's Reagent—black.

Thin-layer Chromatography. *System TA*—Rf 83; *system TB*—Rf 00; *system TC*—Rf 21. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2530.

High Pressure Liquid Chromatography. *System HA*— k' 3.7 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—272 nm ($A_1^1 = 626$ a); aqueous alkali—253 nm. (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1265, 1298, 1204, 752, 985, 790 (KBr disk).

Mass Spectrum. Principal peaks at m/z 266, 267, 224, 220, 268, 44, 250, 248.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 1 µg/ml, FID—D. M. Baaske *et al.*, *J. Chromat.*, 1977, 140, 57–64.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 100 ng/ml, fluorescence detection—R. V. Smith and M. R. De Moreno, *J. Chromat.*, 1983, 274; *Biomed. Appl.*, 25, 376–380.

Dose. 100 µg/kg of apomorphine hydrochloride subcutaneously, as a single dose.

Aprindine

Anti-arrhythmic

N-(3-Diethylaminopropyl)-*N*-indan-2-ylaniline

$C_{22}H_{30}N_2 = 322.5$

CAS—37640-71-4

Aprindine Hydrochloride

Proprietary Names. Amidonal; Fibocil; Fiboran.

$C_{22}H_{30}N_2 \cdot HCl = 359.0$

CAS—33237-74-0

A white to yellowish-white microcrystalline powder. M.p. 127° to 130°. Very soluble in water; freely soluble in ethanol and chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 10.1.

Gas Chromatography. System GA—RI 2475.

Ultraviolet Spectrum. Aqueous acid—260 nm, 266 nm ($A_1^1 = 38$ a), 272 nm; ethanol—258 nm ($A_1^1 = 389$ a), 296 nm ($A_1^1 = 47$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 745, 1510, 1602, 1187, 1258, 1035 (aprindine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 113, 86, 116, 98, 117, 115, 58, 84.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 20 ng/ml, AFID—J. F. Nash and R. H. Carmichael, *J. pharm. Sci.*, 1980, 69, 1094–1096.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: aprindine and monodesethylaprindine, sensitivity 20 ng/ml and 50 ng/ml, respectively, UV detection—T. Kobari *et al.*, *J. Chromat.*, 1983, 278; *Biomed. Appl.*, 29, 220–224.

Disposition in the Body. Almost completely absorbed after oral administration; bioavailability about 75%. Extensively meta-

bolised by aromatic hydroxylation and *N*-dealkylation followed by glucuronic acid conjugation; the monodesethyl metabolite, which can be detected in plasma after chronic administration, is active. Less than 1% of a dose is excreted in the urine as unchanged drug and about 40 to 65% as conjugated metabolites; 35 to 60% of the dose is eliminated in the faeces over a period of 5 days.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.7 to 2 µg/ml.

After a single oral dose of 200 mg to 12 subjects, peak plasma concentrations of 0.6 to 2 µg/ml (mean 0.9) were attained in 2 hours (A. F. Fasola and R. Carmichael, *Acta Cardiol.*, 1974, *Suppl.*, 18, 317–333).

Following daily oral doses of 100 to 150 mg, plasma concentrations in 28 patients ranged from 0.73 to 2.55 µg/ml (J. P. Van Durme *et al.*, *Eur. J. clin. Pharmac.*, 1974, 7, 343–346).

TOXICITY. Toxic effects are usually associated with plasma concentrations greater than 2 µg/ml.

Toxic effects were found in 9 patients whose plasma concentrations ranged from 1.2 to 4.9 µg/ml (mean 2.6) (J. P. Van Durme *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, 12 to 66 hours (mean 30) in normal subjects but the half-life is apparently longer in patients with chronic ventricular arrhythmias and myocardial infarction (average, about 50 hours).

VOLUME OF DISTRIBUTION. About 4 litres/kg.

CLEARANCE. Plasma clearance, about 2.5 ml/min/kg in normal subjects; decreased to about 1 ml/min/kg in patients with cardiac disease.

PROTEIN BINDING. In plasma, more than 95% at therapeutic concentrations, decreasing at higher concentrations.

NOTE. For a review of the pharmacokinetics of anti-arrhythmic agents see R. A. Ronfeld, *Am. Heart J.*, 1980, 100, 978–983.

Dose. 50 to 100 mg of aprindine hydrochloride daily; initial doses of up to 200 mg daily may be given.

Aprobarbitone

Barbiturate

Synonyms. Allylisopropylmalonylurea; Allypropymal; Aprobarbital.

Proprietary Name. Alurate

5-Allyl-5-isopropylbarbituric acid

$C_{10}H_{14}N_2O_3 = 210.2$

CAS—77-02-1

A white crystalline powder. M.p. about 142°.

Soluble 1 in 350 of water, 1 in 30 of boiling water, 1 in 2.5 of ethanol, 1 in 40 of chloroform, and 1 in 5 of ether; soluble in aqueous solutions of alkali hydroxides and carbonates.

Aprobarbitone Sodium

$C_{10}H_{13}N_2NaO_3 = 232.2$

CAS—125-88-2

A white, hygroscopic, microcrystalline powder.

Very **soluble** in water; very slightly soluble in ethanol; practically insoluble in ether.

Dissociation Constant. pK_a 8.0 (25°).

Colour Test. Koppanyi-Zwicker Test—violet.

Thin-layer Chromatography. System TD—Rf 48; system TE—Rf 36; system TF—Rf 65; system TH—Rf 66. (Mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown; Zwicker's reagent, pink.)

Gas Chromatography. System GA—RI 1622.

High Pressure Liquid Chromatography. System HG— k' 3.42; system HH— k' 2.22.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—241 nm ($A_1^1 = 451$ a); M sodium hydroxide (pH 13)—257 nm ($A_1^1 = 331$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1693, 1720, 1745, 1316, 1255, 860 (KBr disk).

Mass Spectrum. Principal peaks at m/z 167, 41, 124, 168, 97, 39, 169, 45; *N*-hydroxyaprobarbitone 41, 43, 183, 167, 140, 184, 124, 109.

Quantification. See also under Amylobarbitone.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In urine: aprobarbitone, *N*-hydroxyaprobarbitone and aprobarbitone diol—J. N. T. Gilbert *et al.*, *J. Pharm. Pharmac.*, 1978, 30, 173–175.

Disposition in the Body. Absorbed after oral administration and slowly excreted in the urine, mainly as metabolites, less than 3% of a dose being excreted as unchanged drug in 24 hours. About 12% of a dose is excreted in the urine as the diol derivative and 4% as *N*-hydroxyaprobarbitone in 3 days, together with 9% as unchanged drug.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 10 to 40 $\mu\text{g/ml}$.

TOXICITY. The estimated minimum lethal dose is 2 g. Plasma concentrations greater than 40 $\mu\text{g/ml}$ are usually associated with toxic effects; concentrations greater than 50 $\mu\text{g/ml}$ may be fatal. In 4 cases of death attributed to overdoses ranging from 2.5 to 7.7 g, antemortem serum concentrations ranged from 120 to 150 $\mu\text{g/ml}$. In 44 cases of overdose in which the patients subsequently recovered, the serum concentrations 24 hours after ingestion were in the range 40 to 130 $\mu\text{g/ml}$ (P. Lous, *Acta pharmac. tox.*, 1954, 10, 261–280).

In a number of fatalities attributed to aprobarbitone, a mean postmortem blood concentration of 50 $\mu\text{g/ml}$ in 9 cases and a mean postmortem liver concentration of 83 $\mu\text{g/g}$ in 12 cases were reported (R. Bonnicksen *et al.*, *J. forens. Sci.*, 1961, 6, 411–443).

HALF-LIFE. Plasma half-life, 0.5 to 1.5 days.

PROTEIN BINDING. In plasma, 55 to 70%.

Dose. 40 to 160 mg daily.

Apronal

Hypnotic/Sedative

Synonyms. Allylisopropylacetylurea; Apronalide.

N-(2-Isopropylpent-4-enoyl)urea

$C_9H_{16}N_2O_2 = 184.2$

CAS—528-92-7

Colourless crystals or white crystalline powder. M.p. 194°.

Soluble 1 in 4000 of water, 1 in 50 of ethanol, 1 in 45 of chloroform, and 1 in 100 of ether.

Thin-layer Chromatography. System TD—Rf 33; system TE—Rf 67; system TF—Rf 64. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1676, 1704, 1092, 1620, 1185, 750 (KBr disk).

Mass Spectrum. Principal peaks at m/z 55, 44, 142, 141, 41, 61, 81, 82.

Dose. Apronal was formerly given in doses of 250 to 750 mg daily.

Arecoline

Purgative/Taenifuge (Veterinary)

Methyl 1,2,5,6-tetrahydro-1-methylnicotinate

$C_8H_{13}NO_2 = 155.2$

CAS—63-75-2

Arecoline is an alkaloid which is obtained from the seeds of *Areca catechu* (Palmae).

An oily liquid which is a strong base. B.p. 209°.

Miscible with water, ethanol, chloroform, and ether.

Arecoline Hydrobromide

$C_8H_{13}NO_2 \cdot HBr = 236.1$

CAS—300-08-3

A white crystalline powder. Unstable in light. M.p. 172° to 175°.

Soluble 1 in 1 of water and 1 in 10 of ethanol; very slightly soluble in chloroform and ether.

Dissociation Constant. pK_a 7.4 (20°).

Thin-layer Chromatography. System TA—Rf 53. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1712, 1262, 1135, 1282, 1020, 1650 (KCl disk).

Mass Spectrum. Principal peaks at m/z 155, 96, 140, 43, 42, 81, 94, 53.

Ascorbic Acid

Vitamin

Synonyms. L-Ascorbic Acid; Cevitamic Acid; Vitamin C.

Proprietary Names of Ascorbic Acid or Sodium Ascorbate. Adenex; Alba-Ce; Ascorbef; Ascorbicap; CC-Kaps; Cebion(e); Cecon; Cemill; Cenolate; Cetane; Cevalin; Cevi-Bid; Ce-Vi-Sol; C-Long; Duoscorb; Megascorb; Redoxon; Roscorbic; Vitascorb; Viterra C. Ascorbic acid is an ingredient of Ce-Cobalin, Oralcer, and Reactivan.

The enolic form of 3-oxo-L-gulofuranolactone

$C_6H_8O_6 = 176.1$

CAS—50-81-7

Colourless crystals or white or very pale yellow crystalline powder. Solutions, especially when made alkaline, deteriorate rapidly in air. M.p. about 190°, with decomposition.

Soluble 1 in 3 to 1 in 3.5 of water, 1 in 25 of ethanol, and 1 in 10 of methanol; soluble in acetone; practically insoluble in chloroform and ether.

Sodium Ascorbate

$C_6H_7NaO_6 = 198.1$

CAS—134-03-2

White or very faintly yellow crystals or crystalline powder. It gradually darkens on exposure to light.

Soluble 1 in 1.3 of water; very slightly soluble in ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 4.2, 11.6 (25°).

Colour Tests. Ammoniacal Silver Nitrate—black; Benedict's Reagent—red; Nessler's Reagent—black; Palladium Chloride—black.

Ultraviolet Spectrum. Aqueous acid—243 nm ($A_1^1 = 556$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1026, 1111, 1312, 1136, 1653, 990 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 29, 41, 39, 42, 69, 116, 167, 168.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum or urine: electrochemical detection—L. A. Pachla and P. T. Kissinger, *Analyt. Chem.*, 1976, 48, 364–367. In urine: UV detection—E. S. Wagner *et al.*, *J. Chromat.*, 1979, 163; *Biomed. Appl.*, 5, 225–229. In postmortem tissues: UV detection—W. J. Allender, *J. analyt. Toxicol.*, 1982, 6, 202–204.

Disposition in the Body. Readily absorbed after oral administration; the proportion of a dose absorbed tends to decrease with increasing dose; it is widely distributed in the body tissues. The concentration of ascorbic acid is higher in leucocytes and platelets than in erythrocytes and plasma. Ascorbic acid is metabolised to dehydroascorbic acid, 2,3-diketogulonic acid, oxalate, and carbon dioxide; some conjugation with sulphate occurs to form ascorbate-3-sulphate. Ascorbic acid in excess of the body's requirements is rapidly eliminated in the urine. About 85% of an intravenous dose, given to subjects previously saturated with the vitamin, is excreted in the urine in 24 hours, with about 70% of the dose excreted unchanged and 15% as dehydroascorbic acid and diketogulonic acid. The amount normally present in the body is in excess of 1.5 g.

BLOOD CONCENTRATION. Concentrations in plasma and in leucocytes are normally about 5 to 12 µg/ml and 25 to 30 µg/10⁸ cells respectively; these concentrations exhibit circadian and seasonal rhythms.

PROTEIN BINDING. In plasma, about 25%.

Dose. 0.2 to 3 g daily.

Aspirin

Analgesic

Synonyms. Acetylsalicylic Acid; Salicylic Acid Acetate.

Proprietary Names. Alka-Seltzer; Angiers; Aspro; Claradin; Disprin; Genasprin; Solprin.

Aspirin is an ingredient of many proprietary preparations—see *Martindale, The Extra Pharmacopoeia*, 28th Edn.

O-Acetylsalicylic acid

C₉H₈O₄ = 180.2

CAS—50-78-2

Colourless or white crystals or white crystalline powder or granules. It is stable in dry air but gradually hydrolyses in contact with moisture to acetic and salicylic acids. M.p. about 143°.

Soluble 1 in 300 of water, 1 in 6 of ethanol, 1 in 17 of chloroform, and 1 in 20 of ether; soluble in solutions of acetates and citrates and, with decomposition, in solutions of alkali hydroxides and carbonates.

Dissociation Constant. pK_a 3.5 (25°).

Partition Coefficient. Log *P* (octanol/pH 7.4), −1.1.

Colour Test. McNally's Test—red (after hydrolysis).

Thin-layer Chromatography. *System TD*—aspirin Rf 18, salicylic acid Rf 07, salicylic acid Rf 00; *system TE*—aspirin Rf 16, salicylic acid Rf 11, salicylic acid Rf 00; *system TF*—aspirin Rf 30, salicylic acid Rf 25, salicylic acid Rf 00.

Gas Chromatography. *System GA*—RI 1309.

High Pressure Liquid Chromatography. *System HD*—aspirin *k'* 0.5, salicylic acid *k'* 0.7; *system HW*—aspirin *k'* 2.7, salicylic acid *k'* 4.6.

Ultraviolet Spectrum. Aqueous acid—230 nm (*A*₁¹ = 466 a), 278 nm (*A*₁¹ = 68 a); aqueous alkali—231 nm (*A*₁¹ = 409 b), 298 nm (*A*₁¹ = 190 b).

Infra-red Spectrum. Principal peaks at wavenumbers 1183, 1688, 1305, 1755, 925, 1219 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 120, 43, 138, 92, 121, 39, 64, 63; salicylic acid 120, 92, 138, 64, 39, 63, 121, 65; salicylic acid 121, 120, 69, 92, 195, 39, 93, 45.

Quantification. GAS CHROMATOGRAPHY. In plasma: aspirin, salicylic acid, and salicylamide, detection limit 200 to 500 ng/ml for all three compounds, FID—M. J. Rance *et al.*, *J. Pharm. Pharmac.*, 1975, 27, 425–429.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: aspirin, salicylic acid, and salicyluric acid, sensitivity 50 ng/ml for aspirin in plasma; also aspirin metabolites in urine, UV detection—J. N. Buskin *et al.*, *Clin. Chem.*, 1982, 28, 1200–1203. In plasma or urine: aspirin and its major metabolites, detection limits in plasma 100 ng/ml for aspirin and salicyluric acid, 500 ng/ml for salicylic acid, and 200 ng/ml for gentisic acid, UV detection—R. H. Rumble *et al.*, *J. Chromat.*, 1981, 225; *Biomed. Appl.*, 14, 252–260.

Disposition in the Body. Readily absorbed after oral administration and rapidly hydrolysed to salicylic acid which is the active agent. Salicylic acid is conjugated with glucuronic acid and glycine to form acyl and ether glucuronides and salicyluric acid; some hydroxylation also occurs to give dihydroxy and trihydroxy derivatives of salicylic acid. Aspirin is excreted almost entirely in the urine with about 50 to 80% of a dose as salicyluric acid, 10 to 30% as salicyl *O*-glucuronide, 5% as salicyl ester glucuronide, and 5 to 10% as free salicylic acid, together with small amounts of gentisic acid, gentisuric acid, and unchanged drug; salicylates are reabsorbed by the renal tubules from acid urine and thus alkaline diuresis increases the rate of salicylate elimination; about 85% of a dose is excreted as free salicylic acid if the urine is made alkaline.

Aspirin is a metabolite of aloxiprin and benorylate.

THERAPEUTIC CONCENTRATION. In plasma, salicylic acid usually in the range 20 to 100 µg/ml for analgesia and 150 to 300 µg/ml for anti-inflammatory effect.

After a single oral dose of 900 mg given to 5 subjects, peak plasma-aspirin concentrations of 16 to 50 µg/ml (mean 37) were attained in about 14 minutes, and peak plasma-salicylic acid concentrations of 47 to 113 µg/ml (mean 78) were reported at 0.5 to 1 hour (B. E. Cham *et al.*, *Ther. Drug Monit.*, 1980, 2, 365–372).

Following daily oral doses of 3.9 g to 8 subjects for 8 days, steady-state plasma-salicylic acid concentrations of 105 to 227 µg/ml (mean 173) were reported; by the 36th day of treatment the steady-state plasma concentrations had declined to 45 to 208 µg/ml (mean 129) (R. H. Rumble *et al.*, *Br. J. clin. Pharmacol.*, 1980, 9, 41–45).

TOXICITY. The estimated minimum lethal dose is 15 g. Plasma concentrations of salicylic acid greater than 300 µg/ml are likely to produce toxic reactions and concentrations greater than 500 µg/ml are associated with moderate to severe intoxication. The maximum permissible atmospheric concentration is 5 mg/m³.

In a review of 62 fatalities attributed to salicylate poisoning, the following postmortem tissue concentrations were reported: blood 61 to 7320 µg/ml (mean 661, 52 cases), brain 22 to 700 µg/g (mean 218, 20 cases), kidney 19 to 1200 µg/g (mean 408, 21 cases), liver 13 to 1000 µg/g (mean 437, 24 cases), spleen 103 to 1230 µg/g (mean 421, 16 cases), urine 180 to 1350 µg/ml (mean 593, 15 cases) (C. J. Rehling, *Poison Residues in Human Tissues*, in *Progress in Chemical Toxicology*, Vol. 3, A. Stolman (Ed.), London, Academic Press Inc., 1967, pp. 363–386).

HALF-LIFE. Plasma half-life, aspirin about 17 minutes, salicylic acid dose-dependent (2 to 4 hours after doses of less than 3 g, increasing to about 19 hours after large doses).

VOLUME OF DISTRIBUTION. Aspirin about 0.15 litre/kg, salicylic acid about 0.1 to 0.2 litre/kg (dose-dependent).

PROTEIN BINDING. In plasma, salicylic acid about 90% at concentrations below 100 µg/ml, decreasing to 50% at concentrations above 400 µg/ml.

NOTE. For reviews of the pharmacokinetics of salicylates see M. Mandelli and G. Tognoni, *Clin. Pharmacokinet.*, 1980, 5, 424–440, and G. Levy, *Pediatrics*, 1978, 62, *Suppl.*, 865–872.

Dose. Usually 1.2 to 4 g daily; doses of up to 8 g daily are given in acute rheumatic disorders.

Atenolol

Beta-adrenoceptor Blocking Agent

Proprietary Names. Tenormin(e). It is an ingredient of Tenoretic.

2-[4-(2-Hydroxy-3-isopropylaminopropoxy)phenyl]acetamide

C₁₄H₂₂N₂O₃ = 266.3

CAS—29122-68-7

Crystals. M.p. 146° to 148°.

Dissociation Constant. pK_a 9.6 (24°).

Partition Coefficient. Log *P* (octanol), 0.23.

Colour Tests. Liebermann's Test—black; Nessler's Reagent—yellow-brown (slow).

Thin-layer Chromatography. System TA—Rf 45; system TB—Rf 00; system TC—Rf 02.

Gas Chromatography. System GA—RI 2355.

High Pressure Liquid Chromatography. System HA—k' 1.3.

Ultraviolet Spectrum. Aqueous acid—274 nm (*A*₁¹ = 48 b), 280 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1633, 1245, 1510, 1184, 805, 820.

Mass Spectrum. Principal peaks at *m/z* 72, 30, 56, 98, 43, 107, 41, 73.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 5 ng/ml, ECD—M. Ervik *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 341–347.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or whole blood: sensitivity 2 ng/ml, fluorescence detection—Y. G. Yee *et al.*, *J. Chromat.*, 1979, 171, 357–362. In plasma, urine, or breast-milk: sensitivity <50 ng/ml, fluorescence detection—D. W. Holt *et al.*, *Br. J. clin. Pharmacol.*, 1982, 14, 148P–149P.

THIN-LAYER CHROMATOGRAPHY. In plasma or urine: detection limits 5 ng/ml in plasma and 500 ng/ml in urine, fluorescence detection—M. Schaefer and E. Mutschler, *J. Chromat.*, 1979, 169, 477–481.

Disposition in the Body. Rapidly but incompletely absorbed after oral administration; bioavailability about 50%. It is excreted almost entirely as unchanged drug, 35 to 50% of an oral dose being excreted in the urine and 30 to 50% in the faeces, in 24 hours; small amounts of 2-hydroxyatenolol and atenolol glucuronide are excreted in the urine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 100 mg given to 12 subjects, peak plasma concentrations of 0.41 to 0.87 µg/ml (mean 0.6) were attained in about 3 hours (J. McAinsh *et al.*, *Biopharm. Drug Disp.*, 1980, 1, 323–332).

Following daily oral doses of 25, 50 and 100 mg to 7, 7, and 6 subjects respectively, mean maximum steady-state plasma concentrations of 0.12, 0.22, and 0.39 µg/ml were reported 4 hours after a dose; the corresponding mean trough concentrations were 0.02, 0.04, and 0.07 µg/ml (T. Ishizaki *et al.*, *Br. J. clin. Pharmacol.*, 1983, 16, 17–25).

TOXICITY. Atenolol is relatively non-toxic; a case of ingestion of 1.2 g with subsequent recovery has been reported.

HALF-LIFE. Plasma half-life, 4 to 14 hours (mean 7).

VOLUME OF DISTRIBUTION. About 0.5 to 1.5 litre/kg.

CLEARANCE. Plasma clearance, about 2 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 0.8 to 0.9.

PROTEIN BINDING. In plasma, less than 5%.

NOTE. For reviews of the pharmacokinetics of atenolol see R. C. Heel *et al.*, *Drugs*, 1979, 17, 425–460, and W. Kirch and K. G. Görg, *Eur. J. drug Met. Pharmacokinet.*, 1982, 7, 81–91.

Dose. 50 to 100 mg daily.

Atrazine

Herbicide

2-Chloro-4-ethylamino-6-isopropylamino-1,3,5-triazine
 $C_8H_{14}ClN_5 = 215.7$
 CAS—1912-24-9

Colourless crystals. M.p. 173° to 175°.

Practically **insoluble** in water; soluble 1 in 20 of chloroform, 1 in 80 of ether, and 1 in 55 of methanol.

Thin-layer Chromatography. System TA—Rf 77.

Gas Chromatography. System GA—RI 1655; system GK—retention time 0.79 relative to caffeine.

Ultraviolet Spectrum. Ethanol—263 nm ($A_1^1 = 195$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1539, 1612, 1295, 804, 1161, 1121 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 58, 44, 200, 68, 215, 41, 42.

Atropine

Anticholinergic

Synonym. (±)-Hyoscyamine

Proprietary Names. Atropinol. It is an ingredient of Riddofan and Riddovydrin.

(1*R*,3*r*,5*S*)-Tropan-3-yl (±)-tropate

$C_{17}H_{23}NO_3 = 289.4$

CAS—51-55-8

An alkaloid obtained from *Duboisia* spp. and other solanaceous plants, or prepared by synthesis.

Colourless crystals or white crystalline powder. M.p. 114° to 118°.

Soluble 1 in 400 of water, 1 in 50 of boiling water, 1 in 3 of ethanol, 1 in 1 of chloroform, and 1 in 60 of ether.

Atropine Sulphate

Proprietary Names. Atropisol; Atropt; Dosatropine; Liotropina. It is an ingredient of Antrocol, Enuretrol, Mydrapred, Mydracaine, and Taumastman.

(C₁₇H₂₃NO₃)₂·H₂SO₄·H₂O = 694.8

CAS—55-48-1 (anhydrous); 5908-99-6 (monohydrate)

Colourless crystals or white crystalline powder. It effloresces in dry air. M.p. about 190°, with decomposition, after drying at 135° for 15 minutes.

Soluble 1 in less than 1 of water and 1 in 4 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 9.9 (20°).

Partition Coefficient. Log *P* (octanol), 1.8.

Colour Test. Liebermann's Test—red-orange.

Thin-layer Chromatography. System TA—Rf 18; system TB—Rf 06; system TC—Rf 03. (*Dragendorff* spray, positive; *acidified iodoplatinate* solution, positive; *Marquis* reagent, pink.)

Gas Chromatography. System GA—RI 2199; system GF—RI 2660.

High Pressure Liquid Chromatography. System HA—k' 3.9 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm (A₁¹ = 6.3 c), 264 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1720, 1035, 1153, 1163, 1063, 1204 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 124, 82, 94, 83, 42, 96, 103, 67.

Quantification. RADIOIMMUNOASSAY. In plasma or serum: atropine and hyoscyamine, detection limit 2.5 ng/ml for both compounds—R. Virtanen *et al.*, *Acta pharmac. tox.*, 1980, 47, 208–212.

Disposition in the Body. Readily absorbed from mucous membranes, skin and the gastro-intestinal tract but not from the stomach. About 80 to 90% of a dose is excreted in the urine in 24 hours, 50% of the dose as unchanged drug, less than 2% as tropic acid and tropine, and about 30% as unknown metabolites. Traces of the dose are eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

Following an intravenous dose of 1 mg to 6 subjects, plasma concentrations of about 0.25 μg/ml were observed at 2 minutes decreasing to 0.005 μg/ml at 20 minutes; following an intramuscular dose of 1 mg to 4 subjects, peak plasma concentrations of about 0.003 μg/ml were attained in 30 minutes (L. Berghem *et al.*, *Br. J. Anaesth.*, 1980, 52, 597–601).

TOXICITY. The amount of a toxic dose appears to vary considerably with individuals. Fatalities are reported to have occurred with doses of 50 to 100 mg but recovery has occurred after administration of 1 g; doses of 10 mg or less may be lethal in children or in susceptible individuals.

A man was found dead after having ingested an unknown amount of atropine sulphate tablets. The blood contained 0.2 μg/ml and the urine 1.5 μg/ml of atropine (B. W. Corbett and A. J. McBay, *Bull. int. Ass. forens. Toxicol.*, 1978, 14(1), 36–37).

HALF-LIFE. Plasma half-life, about 2 to 4 hours; a longer terminal phase of 13 to 38 hours has also been reported.

VOLUME OF DISTRIBUTION. About 2 to 3 litres/kg.

CLEARANCE. Plasma clearance, about 8 ml/min/kg.

PROTEIN BINDING. In plasma, about 50%.

Dose. Usually 0.25 to 2 mg of atropine sulphate daily.

Atropine Methobromide*Anticholinergic*

Synonyms. Atropine Methylbromide; Methylatropine Bromide; Mydrasine.

(1*R*,3*r*,5*S*)-8-Methyl-3-[(\pm)-tropoyloxy]tropanium bromide

$C_{18}H_{26}BrNO_3 = 384.3$

CAS—2870-71-5

Colourless crystals or a white crystalline powder. M.p. about 215°, with decomposition.

Soluble 1 in 1 of water and 1 in 20 of ethanol; very slightly soluble in dehydrated alcohol; practically insoluble in chloroform and ether.

Colour Tests. Aromaticity (Method 2)—colourless/yellow; Liebermann's Test—orange.

Crystals. M.p. 160° to 161°.

Azacyclonol Hydrochloride

Synonym. Azacyclonolium Chloride

Proprietary Name. Frenquel

$C_{18}H_{21}NO \cdot HCl = 303.8$

CAS—1798-50-1

Small white crystals or crystalline powder. M.p. 270° to 281°.

Soluble 1 in 200 of water and 1 in 1000 of ethanol; practically insoluble in acetone, chloroform, ether, and light petroleum.

Colour Tests. Liebermann's Test—brown; Mandelin's Test—red; Marquis Test—yellow.

Thin-layer Chromatography. System TA—Rf 10; system TB—Rf 00; system TC—Rf 03. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2243.

High Pressure Liquid Chromatography. System HA—k' 1.2.

Ultraviolet Spectrum. Aqueous acid—253 nm, 259 nm ($A_1^1 = 17.4$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 702, 745, 1316, 1063, 971, 1155 (KBr disk).

Mass Spectrum. Principal peaks at m/z 85, 84, 183, 105, 56, 77, 55, 30.

Dose. Azacyclonol hydrochloride has been given in doses of 100 to 800 mg daily.

Atropine Methonitrate*Anticholinergic*

Synonym. Methylatropine Nitrate

Proprietary Names. Eumydrin. It is an ingredient of Asma-Vydrin, Brovon, PIB, Riddobron and Rybarvin.

(1*R*,3*r*,5*S*)-8-Methyl-3-[(\pm)-tropoyloxy]tropanium nitrate

$C_{18}H_{26}N_2O_6 = 366.4$

CAS—52-88-0

Colourless crystals or a white crystalline powder. M.p. about 167°.

Soluble 1 in less than 1 of water and 1 in 13 of ethanol; practically insoluble in chloroform and ether. Aqueous solutions are unstable.

Colour Tests. Aromaticity (Method 2)—colourless/violet (transient); Liebermann's Test—orange.

Thin-layer Chromatography. System TA—Rf 02; system TN—Rf 95; system TO—Rf 35. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—252 nm ($A_1^1 =$ about 5), 258 nm ($A_1^1 =$ about 5), 264 nm ($A_1^1 =$ about 4).

Infra-red Spectrum. Principal peaks at wavenumbers 1159, 1045, 1718, 1176, 700, 1212 (Nujol mull).

Atropine Oxide*Anticholinergic*

Atropine *N*-oxide

$C_{17}H_{23}NO_4 = 305.4$

CAS—4438-22-6

A very hygroscopic, crystalline powder. M.p. 127° to 128°; it decomposes at 135°.

Soluble in ethanol and chloroform; practically insoluble in ether.

Atropine Oxide Hydrochloride

Proprietary Names. Génatropine; X-tro.

$C_{17}H_{23}NO_4 \cdot HCl = 341.8$

CAS—4574-60-1

Crystals. M.p. 192° to 193°.

Thin-layer Chromatography. System TA—Rf 21. (Acidified iodoplatinate solution, positive.)

Infra-red Spectrum. Principal peaks at wavenumbers 1164, 1730, 1118, 1026, 1056, 1195.

Azacyclonol*Tranquilliser*

α -Phenyl- α -4-piperidylbenzyl alcohol

$C_{18}H_{21}NO = 267.4$

CAS—115-46-8

Azaperone*Tranquilliser (Veterinary)*

Proprietary Name. Suicalm

4'-Fluoro-4-[4-(2-pyridyl)piperazin-1-yl]butyrophenone

$C_{19}H_{22}FN_3O = 327.4$

CAS—1649-18-9

A white to yellowish-white microcrystalline powder. M.p. 90° to 95°.

Practically **insoluble** in water; soluble 1 in 29 of ethanol, 1 in 4 of chloroform, and 1 in 31 of ether; soluble in dilute organic acids.

Partition Coefficient. Log *P* (octanol), 3.3.

Colour Tests. Cyanogen Bromide—orange; Mandelin's Test—yellow.

Thin-layer Chromatography. System *TA*—Rf 66. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2705.

Ultraviolet Spectrum. Aqueous acid—242 nm ($A_1^1 = 800$ a), 312 nm; methanol—247 nm ($A_1^1 = 1260$ b), 300 nm ($A_1^1 = 200$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1587, 1669, 775, 1236, 1222, 1152 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 107, 165, 123, 95, 121, —, —, —.

Azapetine

Vasodilator

Synonym. Azepine

6-Allyl-6,7-dihydro-5*H*-dibenz[*c,e*]azepine

$C_{17}H_{17}N = 235.3$

CAS—146-36-1

Azapetine Phosphate

Proprietary Name. Ilidar

$C_{17}H_{17}N, H_3PO_4 = 333.3$

CAS—130-83-6

Crystals. M.p. 211° to 215°, with decomposition.

Soluble at least 1 in 100 of water.

Colour Test. Mandelin's Test—brown.

Thin-layer Chromatography. System *TA*—Rf 70; system *TB*—Rf 57; system *TC*—Rf 67. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 1939.

Ultraviolet Spectrum. Aqueous acid—248 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 748, 918, 1063, 990, 1111, 1639 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 165, 234, 194, 235, 193, 196, 166, 179.

Dose. The equivalent of 75 to 225 mg of azapetine has been given daily.

Azapropazone

Analgesic

Synonym. Apazone

Proprietary Names. Prolixan; Rheumox.

5 - Dimethylamino - 9 - methyl - 2 - propylpyrazolo[1,2 - *a*][1,2,4]benzotriazine-1,3(2*H*)-dione dihydrate

$C_{16}H_{20}N_4O_2 \cdot 2H_2O = 336.4$

CAS—13539-59-8 (anhydrous)

Almost colourless crystals. M.p. 228° (anhydrous); 247° to 248° (dihydrate).

Partition Coefficient. Log *P* (octanol/pH 7.4), 1.0.

Colour Tests. Liebermann's Test—grey-green; Mandelin's Test—grey-green.

Thin-layer Chromatography. System *TA*—Rf 68; system *TB*—Rf 53; system *TC*—Rf 05.

Gas Chromatography. System *GA*—RI 2461; system *GF*—RI 3010.

Ultraviolet Spectrum. Azapropazone dihydrate: aqueous acid—250 nm ($A_1^1 = 1040$ b); aqueous alkali—255 nm ($A_1^1 = 1080$ b), 325 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1590, 1640, 1500, 1133, 1270, 1695.

Mass Spectrum. Principal peaks at m/z 160, 300, 189, 145, 188, 301, 161, 42.

Quantification. COLORIMETRY. In serum: sensitivity 10 µg/ml—D. S. Farrier, *Arzneimittel-Forsch.*, 1974, 24, 747–751.

ULTRAVIOLET SPECTROPHOTOMETRY. In plasma: comparison with gas chromatographic and colorimetric methods—H. Leach, *Curr. med. Res. Opinion*, 1976, 4, 35–43.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: detection limits 400 ng/ml for azapropazone and 1.5 to 3 µg/ml for 6-hydroxyazapropazone, UV detection—B. J. Kline *et al.*, *Arzneimittel-Forsch.*, 1983, 33, 504–506.

Disposition in the Body. Readily absorbed after oral administration. About 95% of a dose is excreted in the urine, of which about 60% is unchanged drug and about 20% is the inactive metabolite, 6-hydroxyazapropazone.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 600 mg, administered to 6 subjects, plasma concentrations of 34 to 54 µg/ml (mean 43) were attained in 4 hours (A. E. S. Ritch *et al.*, *Br. J. clin. Pharmacol.*, 1982, 14, 116–119).

Steady-state plasma concentrations of 32 to 89 µg/ml (mean 57) were reported during the daily administration of 800 mg to 10 subjects (S. Thune, *Curr. med. Res. Opinion*, 1976, 4, 70–75).

HALF-LIFE. Plasma half-life, 8 to 24 hours (mean 15), increased in elderly subjects and in subjects with impaired renal or liver function.

VOLUME OF DISTRIBUTION. About 0.2 litre/kg.

CLEARANCE. Plasma clearance, 0.1 to 0.2 ml/min/kg.

PROTEIN BINDING. In plasma, about 99%.

Dose. 0.6 to 1.2 g daily.

Azatadine

Antihistamine

6,11 - Dihydro - 11 - (1 - methyl - 4 - piperidylidene) - 5H - benzo[5,6]cyclohepta[1,2-b]pyridine

$C_{20}H_{22}N_2 = 290.4$

CAS—3964-81-6

Azatadine Maleate

Proprietary Names. Idulian; Optimine; Zadine. It is an ingredient of Congesteze.

$C_{20}H_{22}N_2 \cdot 2C_4H_4O_4 = 522.6$

CAS—3978-86-7

A white crystalline powder. M.p. 145° to 154°.

Soluble in water, ethanol, chloroform, dimethylformamide, and methanol; practically insoluble in ether.

Colour Tests. Cyanogen Bromide—pink; Marquis Test—violet.

Thin-layer Chromatography. System TA—Rf 39. (Acidified potassium permanganate solution, strong reaction.)

Gas Chromatography. System GA—RI 2415.

Ultraviolet Spectrum. Aqueous acid—283 nm ($A_1^1 = 330$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 752, 1271, 1124, 803, 984, 795 (KBr disk).

Dose. 2 to 4 mg of azatadine maleate daily.

Azathioprine

Immunosuppressant

Proprietary Names. Azamune; Imuran; Imurek; Imurel.

6-(1-Methyl-4-nitroimidazol-5-ylthio)purine

 $C_9H_7N_7O_2S = 277.3$

CAS—446-86-6

A pale yellow powder. M.p. about 238°, with decomposition. Practically **insoluble** in water; very slightly soluble in ethanol and chloroform; sparingly soluble in dilute mineral acids; soluble in dilute solutions of alkali hydroxides but decomposes in stronger solutions.

Dissociation Constant. pK_a 8.2 (25°).

Thin-layer Chromatography. System TA—Rf 53; system TB—Rf 03; system TC—Rf 08.

Ultraviolet Spectrum. Aqueous acid—280 nm ($A_1^1 = 600$ a); aqueous alkali—285 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1237, 1306, 1580, 832, 1500, 1531 (KBr disk).

Mass Spectrum. Principal peaks at m/z 231, 42, 119, 232, 92, 65, 67, 74.

Quantification. SPECTROFLUORIMETRY. In plasma: azathioprine and mercaptopurine, sensitivity 10 ng/ml—J. L. Maddocks, *Br. J. clin. Pharmacol.*, 1979, 8, 273–278.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: azathioprine and mercaptopurine, sensitivity 40 ng/ml for azathioprine and 5 ng/ml for mercaptopurine, UV detection—T. L. Ding and L. Z. Benet, *J. Chromat.*, 1979, 163; *Biomed. Appl.*, 5, 281–288.

Wavelength

Disposition in the Body. Absorbed after oral administration and distributed throughout the body. It is readily metabolised to mercaptopurine, which is the major active metabolite, and to 1-methyl-4-nitro-5-(S-glutathionyl)imidazole; other metabolites include 1-methyl-4-nitroimidazole, 1-methyl-4-nitro-5-thioimidazole, and 6-thiouric acid; mercaptopurine is further metabolised to its ribonucleotide, thioinosinic acid, which is the active moiety. About 50% of a dose is excreted in the urine in 24 hours, mainly as thiouric acid and other metabolites with about 10% consisting of unchanged drug; about 12% of a dose is eliminated in the faeces in 48 hours.

THERAPEUTIC CONCENTRATION.

After daily oral doses of 50 to 100 mg to 3 renal transplant patients, peak steady-state plasma concentrations of 0.05 to 0.08 µg/ml of mercaptopurine were reported 1 hour after a dose (T. L. Ding and L. Z. Benet, *ibid.*).

HALF-LIFE. Plasma half-life, azathioprine about 3 hours, mercaptopurine about 0.5 to 1.5 hours.

PROTEIN BINDING. In plasma, about 30%.

Dose. 1 to 5 mg/kg daily, by mouth.

Azinphos-methyl

Pesticide

Synonym. DBD

Proprietary Name. Gusathion

S-(3,4-Dihydro-4-oxobenzo[d][1,2,3]-triazin-3-ylmethyl) OO-dimethyl phosphorodithioate

 $C_{10}H_{12}N_3O_3PS_2 = 317.3$

CAS—86-50-0

Colourless crystals. It is rapidly hydrolysed in alkaline or acid media. M.p. 73° to 74°.

Soluble 1 in 30 000 of water; soluble in ethanol, methanol, and propylene glycol.

Colour Tests. Palladium Chloride—brown; Phosphorus Test—yellow.

Thin-layer Chromatography. System TW—Rf 68.

Gas Chromatography. System GA—RI 2430; system GK—retention time 1.60 relative to caffeine.

Ultraviolet Spectrum. Hexane—285 nm ($A_1^1 = 280$ b), 302 nm, 315 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1000, 1666, 833, 781, 1041, 775.

Mass Spectrum. Principal peaks at m/z 77, 160, 132, 44, 105, 104, 93, 76.

Disposition in the Body.

TOXICITY. Azinphos-methyl is less toxic than mevinphos or parathion. The maximum permissible atmospheric concentration is 0.2 mg/m^3 .

Bacampicillin

Antibiotic

Synonym. Carampicillin

1-(Ethoxycarbonyloxy)ethyl (6R)-6-(α -D-phenylglycylamino)-penicillanate

$\text{C}_{21}\text{H}_{27}\text{N}_3\text{O}_7\text{S} = 465.5$

CAS—50972-17-3

Bacampicillin Hydrochloride

Proprietary Names. Ambaxin; Penglobe; Spectrobid.

$\text{C}_{21}\text{H}_{27}\text{N}_3\text{O}_7\text{S} \cdot \text{HCl} = 502.0$

CAS—37661-08-8

A white crystalline powder.

Soluble 1 in 15 of water, 1 in 7 of ethanol, and 1 in 10 of chloroform; practically insoluble in ether.

Ultraviolet Spectrum. Water—258 nm, 263 nm ($A_1^1 = 13$ b), 269 nm; aqueous alkali—310 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1770, 1075, 1788, 1263, 1687, 1744 (bacampicillin hydrochloride, KBr disk).

Dose. 0.8 to 2.4 g of bacampicillin hydrochloride daily.

Bacitracin

Antibiotic

Proprietary Names. Baciguent; Bacitin. It is an ingredient of Ototripts and Polybactrin Soluble GU.

CAS—1405-87-4

Bacitracin is a polypeptide produced by the growth of an organism of the *licheniformis* group of *Bacillus subtilis*. A white to pale buff hygroscopic powder.

Freely **soluble** in water; soluble in ethanol; practically insoluble in chloroform and ether.

Bacitracin Zinc

Synonyms. Bacitracins Zinc Complex; Zinc Bacitracin.

Proprietary Names. It is an ingredient of Cicatrene, Cicatrex, Cicatrin, Dispray Antibiotic, Polyfax and Tribiotic.

CAS—1405-89-6

A white, pale buff or tan, hygroscopic powder.

Soluble 1 in 900 of water and 1 in 500 of ethanol; very slightly soluble in ether; practically insoluble in chloroform.

Ultraviolet Spectrum. Bacitracin zinc: aqueous acid—252 nm ($A_1^1 = 18$ b).

Baclofen

Muscle Relaxant

Synonym. Aminomethyl Chlorohydrocinnamic Acid

Proprietary Name. Lioresal

4-Amino-3-(4-chlorophenyl)butyric acid

$\text{C}_{10}\text{H}_{12}\text{ClNO}_2 = 213.7$

CAS—1134-47-0

A white crystalline solid. M.p. about 207° .

Slightly **soluble** in water; poorly soluble in organic solvents.

Dissociation Constant. pK_a 3.9, 9.6.

Colour Test. Liebermann's Test—orange.

Thin-layer Chromatography. System TD—Rf 01; system TE—Rf 00; system TF—Rf 00.

Gas Chromatography. System GA—RI 2010.

Ultraviolet Spectrum. Aqueous acid—259 nm, 266 nm ($A_1^1 = 11.3$ a), 274 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1527, 835, 1574, 1495, 1624, 1095 (KBr disk).

Mass Spectrum. Principal peaks at m/z 30, 138, 195, 140, 103, 197, 77, 196.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 50 ng/ml, ECD—P. H. Degen and W. Riess, *J. Chromat.*, 1976, 117, 399–405.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In serum or cerebrospinal fluid: sensitivity 5 ng/ml—C. G. Swahn *et al.*, *J. Chromat.*, 1979, 162; *Biomed Appl.*, 4, 433–438.

Disposition in the Body. Rapidly absorbed after oral administration. About 80% of a dose is excreted in the urine in 24 hours, mostly as unchanged drug. About 15% of a dose is metabolised, mainly to the deaminated derivative; about 20% of a dose may be eliminated in the faeces as unchanged drug and metabolites.

THERAPEUTIC CONCENTRATION.

After an oral dose of 40 mg to 1 subject, a peak plasma concentration of unchanged drug of about 0.6 µg/ml was attained in 2 hours; a peak concentration of metabolites of about 0.1 µg/ml was attained in about 4 hours (J. W. Faigle and H. Keberle, *Postgrad. med. J.*, 1972, 48 (Oct.), *Suppl.*, 9–13).

TOXICITY. Recovery has occurred after the ingestion of 1.5 g. Coma, respiratory failure and severe seizures occurred in a 39-year-old female subject after ingestion of 450 mg; following treatment, the patient regained consciousness within 36 hours, at which time a plasma concentration of 0.2 µg/ml was reported; the plasma half-life was found to be 35 hours (K. Ghose *et al.*, *Postgrad. med. J.*, 1980, 56, 865–867).

HALF-LIFE. Plasma half-life, about 2 to 4 hours.

PROTEIN BINDING. In plasma, about 30%.

Dose. 15 to 60 mg daily; maximum of 100 mg daily.

Bamethan

Vasodilator

2-Butylamino-1-(4-hydroxyphenyl)ethanol

$C_{12}H_{19}NO_2 = 209.3$

CAS—3703-79-5

Crystals. M.p. 123.5° to 125°.

Bamethan Sulphate

Proprietary Names. Vasculat; Vasculit.

$(C_{12}H_{19}NO_2)_2 \cdot H_2SO_4 = 516.6$

CAS—5716-20-1

Soluble in water.

Dissociation Constant. pK_a 9.0, 10.2 (25°).

Colour Tests. Folin-Ciocalteu Reagent—blue; Liebermann's Test—violet-brown; Mandelin's Test—blue → green.

Thin-layer Chromatography. *System TA*—Rf 55; *system TB*—Rf 04; *system TC*—Rf 06. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. *System GA*—RI 1920.

High Pressure Liquid Chromatography. *System HA*— k' 0.9.

Ultraviolet Spectrum. Aqueous acid—275 nm ($A_1^1 = 64$ a); aqueous alkali—242 nm, 290 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 832, 1228, 1066, 1264, 1494, 1108 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 30, 57, 108, 44, 29, 84, 41.

Disposition in the Body. Rapidly absorbed after oral administration. About 80% of a dose is excreted in the urine in 24 hours, with about 30% of the dose as unchanged drug.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 25 mg given to 5 subjects, peak serum concentrations of 0.04 to 0.11 µg/ml (mean 0.07) were attained in 0.5 to 1 hour (J. H. Hengstmann and B. Steinkamp, *Arzneimittel-Forsch.*, 1981, 31, 843–848).

HALF-LIFE. Plasma half-life, about 2.5 hours.

VOLUME OF DISTRIBUTION. 2.5 to 5 litres/kg (mean 3.7).

CLEARANCE. Plasma clearance, 12 to 20 ml/min/kg (mean 16).

REFERENCE. J. H. Hengstmann and B. Steinkamp, *ibid.*

Dose. 100 mg of bamethan sulphate daily.

Bamifylline

Xanthine Bronchodilator

8 - Benzyl - 7 - [2 - (N - ethyl - 2 - hydroxyethylamino)ethyl]-theophylline

$C_{20}H_{27}N_5O_3 = 385.5$

CAS—2016-63-9

Crystals. M.p. 80°.

Bamifylline Hydrochloride

Proprietary Name. Trentadil

$C_{20}H_{27}N_5O_3 \cdot HCl = 421.9$

CAS—20684-06-4

A crystalline solid. M.p. about 185°.

Soluble in water.

Colour Test. Amalic Acid Test—orange/violet.

Thin-layer Chromatography. *System TA*—Rf 65; *system TB*—Rf 00; *system TC*—Rf 54. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—278 nm ($A_1^1 = 310$ a); methanol—277 nm ($A_1^1 = 280$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1650, 1698, 1538, 729, 1041, 1205 (KBr disk).

Mass Spectrum. Principal peaks at m/z 102, 84, 58, 56, 42, 30, 103, 91.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: bamifylline and desalkyl metabolites, sensitivity 10 ng/ml, UV detection—G. Nicot *et al.*, *J. Chromat.*, 1983, 277; *Biomed. Appl.*, 28, 239–249.

Dose. Bamifylline hydrochloride has been given in doses of 0.9 to 1.8 g daily.

Bamipine

Antihistamine

N - Benzyl - N - (1 - methyl - 4 - piperidyl)aniline

$C_{19}H_{24}N_2 = 280.4$

CAS—4945-47-5

Crystals. M.p. about 115°.

Soluble 1 in 75 of water.

Bamipine Hydrochloride

Proprietary Names. Soventol; Taumidine.

$C_{19}H_{24}N_2 \cdot 2HCl = 353.3$

CAS—61732-85-2

A white crystalline powder. M.p. 208° to 209°.

Colour Tests. Liebermann's Test—red-orange; Mandelin's Test—brown.

Thin-layer Chromatography. *System TA*—Rf 49; *system TB*—Rf 40; *system TC*—Rf 43. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2211.

Ultraviolet Spectrum. Aqueous acid—257 nm ($A_1^1 = 16$ b); methanol—251 nm ($A_1^1 = 439$ b), 298 nm ($A_1^1 = 62$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 745, 1593, 725, 1495, 690, 1275 (KBr disk).

Mass Spectrum. Principal peaks at m/z 97, 43, 71, 70, 96, 91, 98, 42.

Dose. Bampine hydrochloride has been given in doses of 75 to 400 mg daily.

Barbitone

Barbiturate

Synonyms. Barb; Barbitol; Diemalum; Diethylmalonylurea; Malonal.

5,5-Diethylbarbituric acid

$C_8H_{12}N_2O_3 = 184.2$

CAS—57-44-3

Colourless crystals or white crystalline powder. M.p. 188° to 192° .

Soluble 1 in 160 of water, 1 in 13 of boiling water, 1 in 15 of ethanol, 1 in 6 of acetone, 1 in 75 of chloroform, and 1 in 40 of ether; soluble in ethyl acetate and in solutions of alkali carbonates and hydroxides.

Barbitone Sodium

Synonyms. Diemalnatium; Soluble Barbitone.

$C_8H_{11}N_2NaO_3 = 206.2$

CAS—144-02-5

A white crystalline powder. A solution in water slowly decomposes. M.p. about 190° .

Soluble 1 in 5 of water and 1 in 600 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 8.0 (25°).

Colour Tests. Koppanyi-Zwicker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. System TD—Rf 41; system TE—Rf 31; system TF—Rf 61; system TH—Rf 51. (Mercuric chloride-diphenylcarbazone reagent, positive; mercurous nitrate spray, black; Zwicker's reagent, pink.)

Gas Chromatography. System GA—RI 1497; system GF—RI 2230.

High Pressure Liquid Chromatography. System HG— k' 1.11; system HH— k' 0.63.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—239 nm ($A_1^1 = 549$ a); M sodium hydroxide (pH 13)—254 nm ($A_1^1 = 427$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1680, 1720, 1767, 1320, 1245, 875 (KBr disk).

Mass Spectrum. Principal peaks at m/z 156, 141, 55, 155, 98, 39, 82, 43.

Quantification. See under Amytobarbitone.

Disposition in the Body. Readily absorbed after oral administration. It is excreted slowly in the urine almost entirely as unchanged drug; about 2% of a dose is excreted in 8 hours, about 16% in 32 hours and detectable amounts may still be present in the urine after 16 days.

Barbitone is a metabolite of metharbitone.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 5 to 30 $\mu\text{g/ml}$.

TOXICITY. The estimated minimum lethal dose is 2 g. Toxic effects may be produced with blood concentrations of about 20 $\mu\text{g/ml}$ or more and concentrations greater than 90 $\mu\text{g/ml}$ may be lethal.

In 6 cases of acute poisoning, the amounts ingested ranged from 5 to about 25 g. In 2 cases, death ensued after 150 and 160 hours when the serum concentrations were about 100 and 170 $\mu\text{g/ml}$ respectively. In the other 4 cases, the serum concentrations on awakening from coma were 70 to 150 $\mu\text{g/ml}$ (P. Lou, *Acta pharmac. tox.*, 1954, 10, 147-165 and 261-280).

HALF-LIFE. Plasma half-life, about 2 days.

VOLUME OF DISTRIBUTION. About 0.5 litre/kg.

SALIVA. Plasma: saliva ratio, about 1.

PROTEIN BINDING. In plasma, less than 20%.

Dose. Barbitone has been given in a dose of 300 to 600 mg.

Barbituric Acid

Synonym. Malonylurea

Pyrimidine-2,4,6-trione

$C_4H_4N_2O_3 = 128.1$

CAS—67-52-7

Crystals. M.p. about 248°, with some decomposition.

Dissociation Constant. pK_a 4.0.

Thin-layer Chromatography. *System TD*—Rf 00; *system TE*—Rf 00; *system TF*—Rf 00; *system TH*—Rf 03.

Ultraviolet Spectrum. *Borax buffer 0.05M* (pH 9.2)—257 nm; *M sodium hydroxide* (pH 13)—259 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1710, 1734, 1750, 1225, 775, 1190 (KBr disk).

Mass Spectrum. Principal peaks at m/z 42, 128, 85, 43, 44, 41, 70, 69.

Beclamide

Anticonvulsant

Synonyms. Benzchlorpropamide; Chloroethylphenamide.

Proprietary Names. Neuracen; Nydrane; Posedrine.

N-Benzyl-3-chloropropionamide

$C_{10}H_{12}ClNO = 197.7$

CAS—501-68-8

Colourless crystals. M.p. 91° to 94°.

Practically **insoluble** in water; soluble 1 in 14 of ethanol, 1 in 5 of chloroform, and 1 in less than 100 of ether.

Colour Test. Liebermann's Test—red-orange.

Thin-layer Chromatography. *System TA*—Rf 65; *system TB*—Rf 08; *system TC*—Rf 65. (*Acidified potassium permanganate solution*, positive, developing slowly.)

Gas Chromatography. *System GA*—RI 1480 and 1678.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm, 264 nm; methanol—252 nm, 258 nm ($A_1^1 = 9.6$ b), 264 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1640, 696, 736, 1558, 1275, 1290 (KBr disk).

Mass Spectrum. Principal peaks at m/z 91, 106, 197, 162, 107, 148, 27, 63.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 200 ng/ml, FID—O. P. Jones *et al.*, *Br. J. clin. Pharmac.*, 1975, 2, 364–365.

Disposition in the Body. Absorbed after oral administration. Less than 0.5% of a dose is excreted in the urine as unchanged drug in 24 hours; a metabolite, tentatively identified as an *N*-hydroxybenzyl-3-chloropropionamide, has been detected in the urine as a glucuronide conjugate.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 1 g to 6 subjects, peak plasma concentrations of 8.7 to 18.9 $\mu\text{g/ml}$ (mean 13) were attained in 1 to 4 hours (H. Leach *et al.*, *Br. J. clin. Pharmac.*, 1975, 2, 377P–378P).

Dose. 1.5 to 4 g daily.

Beclomethasone

Corticosteroid

Synonyms. Beclometasone; 9 α -Chloro-16 β -methylprednisolone. 9 α -Chloro-11 β ,17 α ,21-trihydroxy-16 β -methylpregna-1,4-diene-3,20-dione
 $\text{C}_{22}\text{H}_{29}\text{ClO}_5 = 408.9$
 CAS—4419-39-0

Beclomethasone Dipropionate

Proprietary Names. Aldecin; Becloforte; Beclovent; Beconase; Becotide; Clenil; Propaderm; Sanasthmyl; Turbinal; Vancenase; Vanceril; Viarox. It is an ingredient of Ventide.

$\text{C}_{28}\text{H}_{37}\text{ClO}_7 = 521.0$

CAS—5534-09-8

A white to creamy-white powder. M.p. about 212°, with decomposition. Practically **insoluble** in water; soluble 1 in 60 of ethanol and 1 in 8 of chloroform; freely soluble in acetone.

Colour Tests. Naphthol-Sulphuric Acid—green/brown-yellow; Sulphuric Acid—orange (slow).

Thin-layer Chromatography. Beclomethasone dipropionate: *system TP*—Rf 75; *system TQ*—Rf 38; *system TR*—Rf 89; *system TS*—Rf 42, streaking may occur. (p-Toluenesulphonic acid solution, positive.)

High Pressure Liquid Chromatography. *System HT*—k' 4.2.

Ultraviolet Spectrum. Beclomethasone dipropionate: dehydrated alcohol—239 nm ($A_1^1 = 292$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1190, 1658, 1730, 1608, 890, 1053 (beclomethasone dipropionate, KBr disk).

Dose. Usually 300 to 400 μg of beclomethasone dipropionate daily, by aerosol inhalation; maximum of 2 mg daily.

Bemegride

Respiratory Stimulant

Synonym. Methetharimide

Proprietary Names. Eukraton; Megimide.

3-Ethyl-3-methylglutarimide

$\text{C}_8\text{H}_{13}\text{NO}_2 = 155.2$

CAS—64-65-3

White flakes or crystalline powder. M.p. 126° to 128°.

Soluble 1 in 170 of water, 1 in 30 of ethanol, 1 in 12 of acetone, 1 in 4 of chloroform, and 1 in 100 of ether; soluble in aqueous solutions of alkali hydroxides.

Bemegride SodiumC₈H₁₂NNaO₂ = 177.2

CAS—25334-00-3

A fine white powder.

Soluble 1 in 11 of water and 1 in 20 of ethanol; practically insoluble in acetone and ether.**Dissociation Constant.** pK_a 11.6.**Colour Tests.** Koppanyi–Zwikker Test—violet; Mercurous Nitrate—black.**Thin-layer Chromatography.** System TD—Rf 52; system TE—Rf 68; system TF—Rf 53. (Mercuric chloride–diphenylcarbazone reagent, positive; mercurous nitrate spray, black.)**Gas Chromatography.** System GA—RI 1373; system GC—RI 1253.**Ultraviolet Spectrum.** No significant absorption, 230 to 360 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1680, 1277, 1730, 860, 1160, 1145 (KBr disk).**Mass Spectrum.** Principal peaks at *m/z* 55, 83, 82, 41, 113, 70, 29, 69.**Disposition in the Body.** Metabolised by hydroxylation of the ethyl side-chain and excreted in the urine as unchanged drug and as the hydroxy metabolite.**Dose.** Bemegride has been given in doses of 25 to 50 mg intravenously, repeated as necessary.**Benactyzine***Tranquilliser*

2-Diethylaminoethyl benzilate

C₂₀H₂₅NO₃ = 327.4

CAS—302-40-9

Crystals. M.p. 51°.

Benactyzine Hydrochloride*Proprietary Name.* It is an ingredient of Deprol.C₂₀H₂₅NO₃·HCl = 363.9

CAS—57-37-4

A white crystalline powder. M.p. 177° to 181°.

Soluble 1 in 14 of water and 1 in 22 of ethanol; very slightly soluble in ether.**Dissociation Constant.** pK_a 6.6.**Colour Tests.** Liebermann's Test—orange → brown; Marquis Test—orange → green → blue; Sulphuric Acid—orange.**Thin-layer Chromatography.** System TA—Rf 66; system TB—Rf 40; system TC—Rf 53. (Acidified iodoplatinate solution, positive.)**Gas Chromatography.** System GA—RI 2248.**High Pressure Liquid Chromatography.** System HA—k' 1.7.**Ultraviolet Spectrum.** Aqueous acid—252 nm, 258 nm (A₁¹ = 14 a), 262 nm, 264 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 695, 1723, 1231, 1054, 1162, 751 (KBr disk).**Mass Spectrum.** Principal peaks at *m/z* 86, 105, 77, 87, 182, 99, 183, 58.**Disposition in the Body.** Rapidly metabolised and excreted.**Dose.** 3 to 9 mg of benactyzine hydrochloride daily.**Benapryzine***Anticholinergic**Synonym.* Benaprizine2-(*N*-Ethylpropylamino)ethyl benzilateC₂₁H₂₇NO₃ = 341.4

CAS—22487-42-9

**Benapryzine Hydrochloride**C₂₁H₂₇NO₃·HCl = 377.9

CAS—3202-55-9

A white crystalline powder. M.p. about 166°.

Soluble 1 in 35 of water, 1 in 56 of dehydrated alcohol, 1 in 120 of acetone, and 1 in 8 of chloroform.**Ultraviolet Spectrum.** Aqueous acid—251 nm, 257 nm, 261 nm, 264 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1753, 1215, 700, 690, 1180, 1020 (benapryzine hydrochloride, KCl disk).**Dose.** 150 to 200 mg of benapryzine hydrochloride daily.**Bendrofluazide***Diuretic**Synonyms.* Bendroflumethiazide; Benzydroflumethiazide.*Proprietary Names.* Aprinox; Berkoxide; Centyl; Naturetin; Neo-NaClex; Pluryl; Polidiuril; Salural; Sinesalin; Urizide. It is an ingredient of Abicol, Corgaretic, Inderetic, Inderex, Prestim, Rauzide, and Tenavoid.3-Benzyl-3,4-dihydro-6-trifluoromethyl-2*H*-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxideC₁₅H₁₄F₃N₃O₄S₂ = 421.4

CAS—73-48-3

A white or cream-coloured crystalline powder. M.p. about 220°, with decomposition.

Practically **insoluble** in water and chloroform; soluble 1 in 17 of ethanol, 1 in 1.5 of acetone, and 1 in 500 of ether.

Dissociation Constant. pK_a 8.5 (25°).

Colour Tests. Koppanyi-Zwicker Test—violet; Liebermann's Test—blue; Sulphuric Acid—violet.

Thin-layer Chromatography. System TD—Rf 25; system TE—Rf 52; system TF—Rf 71. (Location under ultraviolet light, violet fluorescence.)

High Pressure Liquid Chromatography. System HN— k' 15.35.

Ultraviolet Spectrum. Aqueous acid—273 nm ($A_1^1 = 585$ a), 325 nm; aqueous alkali—273 nm ($A_1^1 = 410$ a), 330 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1170, 1155, 1306, 1518, 1621, 750 (KBr disk). There are 2 polymorphic forms.

Mass Spectrum. Principal peaks at m/z 330, 118, 91, 319, 219, 64, 92, 421.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 5 ng/ml, ECD—B. Beerman *et al.*, *Eur. J. clin. Pharmac.*, 1976, 10, 293–295.

Disposition in the Body. Readily and almost completely absorbed after oral administration. Up to about 30% of a dose is excreted unchanged in the urine in 48 hours; the remainder is excreted as unidentified metabolites.

THERAPEUTIC CONCENTRATION.

A single oral dose of 10 mg given to 9 subjects, produced peak plasma concentrations of 0.07 to 0.10 µg/ml in 1.6 to 2.4 hours (B. Beerman *et al.*, *Clin. Pharmac. Ther.*, 1977, 22, 385–388).

Peak plasma concentrations of 0.04 to 0.06 µg/ml (mean 0.05) were reported 2 hours after a dose, following administration of 5 mg daily to 8 hypertensive patients (B. Beerman *et al.*, *Eur. J. clin. Pharmac.*, 1978, 13, 119–124).

HALF-LIFE. Plasma half-life, about 9 hours.

VOLUME OF DISTRIBUTION. About 1.5 litres/kg.

PROTEIN BINDING. In plasma, about 94%.

NOTE. For a review of the clinical pharmacokinetics of diuretics see B. Beerman and M. Groschinsky-Grind, *Clin. Pharmacokin.*, 1980, 5, 221–245.

Dose. 2.5 to 10 mg daily.

Benethamine

Pharmaceutical Adjuvant

N-Benzylphenethylamine
 $C_{15}H_{17}N = 211.3$

Soluble in chloroform.

Colour Tests. Liebermann's Test—red-orange; Marquis Test—orange-brown → brown.

Thin-layer Chromatography. System TA—Rf 64; system TB—Rf 48; system TC—Rf 59. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1798.

Ultraviolet Spectrum. Water—258 nm ($A_1^1 = 12$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 696, 745, 1111, 1022, 1592, 1067 (KBr disk).

Mass Spectrum. Principal peaks at m/z 91, 120, 65, 121, 92, 105, 77, 118.

Benorylate

Analgesic

Synonyms. Benorilate; Fenasprate.

Proprietary Names. Benoral; Benortan; Salipran.

4-Acetamidophenyl *O*-acetylsalicylate

$C_{17}H_{15}NO_5 = 313.3$

CAS—5003-48-5

A white crystalline powder. M.p. 178° to 181°. Practically **insoluble** in water; soluble 1 in 88 of ethanol, 1 in 22 of acetone, 1 in 18 of chloroform, and 1 in 900 of ether.

Colour Tests. Liebermann's Test—black; Mandelin's Test—green; Marquis Test—violet.

Thin-layer Chromatography. System TA—Rf 67; system TB—Rf 00; system TC—Rf 51. (Marquis reagent, positive.)

Gas Chromatography. System GA—benorylate RI 1840, aspirin RI 1309, paracetamol RI 1687.

High Pressure Liquid Chromatography. System HD—benorylate k' 0.7, aspirin k' 0.5, paracetamol k' 0.1; system HW—benorylate k' 22.4, aspirin k' 2.7, paracetamol k' 0.32.

Ultraviolet Spectrum. Dehydrated alcohol—240 nm ($A_1^1 = 740$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1182, 1050, 1661, 1730, 1248, 1194, (KBr disk).

Mass Spectrum. Principal peaks at m/z 121, 163, 151, 109, 43, 122, 108, 65; aspirin 120, 43, 138, 92, 121, 39, 64, 63; paracetamol 109, 151, 43, 80, 108, 81, 53, 52.

Quantification. See also under Aspirin and Paracetamol.

GAS CHROMATOGRAPHY. In plasma: aspirin and salicylic acid, sensitivity 2 µg/ml for aspirin, FID—A. Cailleux *et al.*, *Therapie*, 1979, 34, 73–79.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: benorylate and paracetamol, sensitivity 200 ng/ml for benorylate and 400 ng/ml for paracetamol, UV detection—A. Cailleux *et al.*, *ibid.*

Disposition in the Body. Readily absorbed after oral administration. It is hydrolysed in the blood to aspirin and paracetamol, and about 85% of a dose is excreted in the urine in 72 hours by the normal metabolic routes for these substances. About 15% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

Following oral administration of 4 g as a suspension to 20 subjects, mean peak plasma concentrations of 2.2 µg/ml of benorylate and about 120 µg/ml of salicylate were attained in 0.5 and 3 hours respectively (M. Aylward *et al.*, *Scand. J. Rheumatol.*, 1976, *Suppl.* 13, 9–12).

HALF-LIFE. Plasma half-life, about 1 hour.

Dose. 4.5 to 8 g daily.

Benoxaprofen

Analgesic

Proprietary Names. Opren; Oraflex.

2-[2-(4-Chlorophenyl)benzoxazol-5-yl]propionic acid

$C_{16}H_{12}ClNO_3 = 301.7$

CAS—51234-28-7

A cream-coloured solid. M.p. 189° to 190°.

Dissociation Constant. pK_a 3.5.

Thin-layer Chromatography. System TG—Rf 14. (Ludy Tenger reagent, orange.)

Gas Chromatography. System GD—retention time of methyl derivative 1.98 relative to $n-C_{16}H_{34}$.

High Pressure Liquid Chromatography. System HD— k' 11.3; system HV—retention time 0.98 relative to meclofenamic acid.

Ultraviolet Spectrum. Aqueous alkali—244 nm ($A_1^1 = 295$ b), 309 nm ($A_1^1 = 900$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 728, 1695, 833, 1086, 1050, 1010 (KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 256, 301, 91, 258, 119, 65, 257, 303.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 10 ng/ml, ECD—D. H. Chatfield and T. J. Woodage, *J. Chromat.*, 1978, 153, 101–106.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: detection limit 25 ng/ml, UV detection—L. Ekman *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 478–481.

Disposition in the Body. Readily absorbed after oral administration. About 15% of a dose is excreted in the urine in 24 hours, mainly as the glucuronic acid conjugate, together with small

amounts of unchanged drug. In 5 days about 60% of a dose is excreted in the urine and 40% is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 400 mg, administered to 4 subjects, a mean peak plasma concentration of 45 µg/ml was attained in 2 to 4 hours (G. L. Smith *et al.*, *Br. J. clin. Pharmac.*, 1977, 4, 585–590).

TOXICITY. Because of reports of adverse reactions and fatalities, benoxapropfen was withdrawn worldwide in 1982.

HALF-LIFE. Plasma half-life, about 30 to 35 hours; increased in renal impairment.

PROTEIN BINDING. In plasma, more than 99%.

Dose. Benoxapropfen has been given in doses of 600 mg daily.

Benperidol

Tranquilliser

Synonym. Benzperidol

Proprietary Names. Anquil; Frenactil; Glianimon.

1-[1-[3-(4-Fluorobenzoyl)propyl]-4-piperidyl]benzimidazolin-2-one

$C_{22}H_{24}FN_3O_2 = 381.4$

CAS—2062-84-2

An off-white amorphous powder or crystals. It darkens slowly on exposure to light. M.p. 170° to 175°.

Practically **insoluble** in water; soluble 1 in 1000 of ethanol, 1 in 4 of chloroform, and 1 in 625 of ether; sparingly soluble in dilute mineral acids.

Colour Tests. Koppanyi-Zwicker Test—violet; Mandelin's Test—violet; Mercurous Nitrate—black.

High Pressure Liquid Chromatography. System HA—k' 1.1.

Ultraviolet Spectrum. Aqueous acid—231 nm, 249 nm ($A_1^1 = 348$ b), 279 nm; aqueous alkali—248 nm ($A_1^1 = 445$ b), 288 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1694, 757, 1587, 1162, 1204, 1219.

Mass Spectrum. Principal peaks at m/z 230, 109, 82, 187, 243, 363, 42, 123.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 30 ng/ml, FID—M. P. Quaglio *et al.*, *Boll. chim.-farm.*, 1982, 121, 276–284.

Dose. 0.25 to 1.5 mg daily.

Benserazide

Dopa-decarboxylase Inhibitor

Synonym. Serazide

DL-2-Amino-3-hydroxy-2'-(2,3,4-trihydroxybenzyl)propionohydrazide

$C_{10}H_{15}N_3O_5 = 257.2$

CAS—322-35-0

Benserazide Hydrochloride

Proprietary Names. It is an ingredient of Madopar and Prolopa.

$C_{10}H_{15}N_3O_5 \cdot HCl = 293.7$

CAS—14919-77-8; 14046-64-1

An off-white crystalline powder.

Soluble 1 in 3 of water, 1 in 118 of ethanol, 1 in 66 of acetone, 1 in 180 of chloroform, and 1 in 455 of ether.

Colour Tests. Ammoniacal Silver Nitrate—black; *p*-Dimethylaminobenzaldehyde—red/-; Ferric Chloride—green-brown; Folin-Ciocalteu Reagent—blue; Methanolic Potassium Hydroxide—red; Millon's Reagent—red-orange; Nessler's Reagent—black; Palladium Chloride—orange → brown; Potassium Dichromate—brown.

Thin-layer Chromatography. System TA—Rf 01; system TB—Rf 00; system TC—Rf 01.

Ultraviolet Spectrum. Aqueous acid—272 nm ($A_1^1 = 36.5$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1500, 1665, 1593, 1195, 1570, 1265 (KBr disk).

Mass Spectrum. Principal peaks at m/z 60, 42, 88, 30, 31, 43, 29, 70.

Disposition in the Body. Rapidly absorbed after oral administration and appears to be rapidly metabolised. About 50 to 60% of an oral dose and 80% of an intravenous dose is excreted in the urine in 24 hours, and about 30% and 10% of the respective doses are eliminated in the faeces in 7 days.

THERAPEUTIC CONCENTRATION.

After an oral dose of 50 mg of ^{14}C -benserazide hydrochloride, peak plasma concentrations of about 1 $\mu\text{g/ml}$ were attained in 1 hour (D. E. Schwartz *et al.*, *Eur. J. clin. Pharmac.*, 1974, 7, 39–45).

Dose. Usually the equivalent of 50 mg of benserazide daily, increasing to 100 to 250 mg daily (given in combination with levodopa in the treatment of parkinsonism).

Benzaldehyde

Flavouring Agent

Synonym. Artificial Essential Oil of Almond

$\text{C}_6\text{H}_5 \cdot \text{CHO} = 106.1$

CAS—100-52-7

A clear, colourless, strongly refractive liquid, with a characteristic odour of bitter almonds. It becomes yellowish on storage and oxidises in air to benzoic acid. B.p. about 179°. Refractive index, at 20°, 1.544 to 1.5465.

Soluble 1 in 350 of water; miscible with ethanol and ether.

Gas Chromatography. System GA—RI 947; system GI—retention time 34.2 min.

Ultraviolet Spectrum. Ethanol—245 nm ($A_1^1 = 1294$ b), 279 nm ($A_1^1 = 126$ b), 289 nm ($A_1^1 = 105$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1700, 1210, 1601, 1175, 1318, 753 (thin film).

Mass Spectrum. Principal peaks at m/z 77, 106, 105, 51, 50, 78, 52, 39.

Quantification. GAS CHROMATOGRAPHY. In blood: detection and identification of volatile compounds using head-space analysis and FID—J. D. Ramsey and R. J. Flanagan, *J. Chromat.*, 1982, 240, 423–444.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In serum: head-space analysis—A. Zlatkis *et al.*, *J. Chromat.*, 1974, 91, 379–383.

Benzalkonium Chloride

Cationic Disinfectant

Proprietary Names. Benzalchlor-50; Cetal Conc. A and B; Empigen BAC; Hyamine 3500; Laudamonium; Morpan BC; Ovules Pharmatex; Quartamon; Roccal; Sabol; Silquat B10; Silquat B50; Vantoc CL; Zephiran. It is an ingredient of Polycide, Stomosol, and Timodine.

A mixture of alkylbenzyltrimethylammonium chlorides of the general formula $[\text{C}_6\text{H}_5 \cdot \text{CH}_2 \cdot \text{N}(\text{CH}_3)_3 \cdot \text{R}]\text{Cl}$, in which R represents a mixture of the alkyls from C_8H_{17} to $\text{C}_{18}\text{H}_{37}$.

CAS—8001-54-5

A white or yellowish-white amorphous powder, thick gel, or gelatinous pieces. A solution in water gives a clear, colourless or pale yellow, syrupy liquid, which foams strongly when shaken. Very **soluble** in water, ethanol, and acetone; practically insoluble in ether.

Ultraviolet Spectrum. Water—256 nm ($A_1^1 = 4.9$ b), 262 nm ($A_1^1 = 5.8$ b), 268 nm ($A_1^1 = 4.6$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 702, 726, 780, 875, 1618, 1211 (thin film).

Benzbromarone

Uricosuric

Proprietary Names. Desuric; Nancaricin; Normurat; Uricovac M.

3,5-Dibromo-4-hydroxyphenyl 2-ethylbenzofuran-3-yl ketone

$\text{C}_{17}\text{H}_{12}\text{Br}_2\text{O}_3 = 424.1$

CAS—3562-84-3

Yellowish crystals. M.p. 151°.

Ultraviolet Spectrum. Methanolic acid—237 nm ($A_1^1 = 666$ b), 274 nm (inflection), 281 nm ($A_1^1 = 314$ b); aqueous alkali—240 nm ($A_1^1 = 440$ b), 281 nm (inflection), 355 nm ($A_1^1 = 513$ b).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: benzbromarone and benzarone, detection limits 140 and 90 ng/ml, respectively, UV detection—H. Vergin and G. Bishop, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 383–386.

Disposition in the Body. Incompletely absorbed after oral administration. It is metabolised by debromination to bromobenzarone and benzarone which are both active metabolites. About 50% of a dose is excreted in the bile as free and conjugated (glucuronide) metabolites and less than 10% of a dose is excreted in the urine.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 100 mg to 7 subjects, peak plasma concentrations of 1.4 to 2.9 µg/ml (mean 2.2) of benzbromarone and 0.6 to 1.2 µg/ml (mean 0.8) of benzarone were attained in about 3 and 6 hours respectively (H. Ferber *et al.*, *Eur. J. clin. Pharmac.*, 1981, 19, 431-435).

HALF-LIFE. Plasma half-life, benzbromarone about 3 hours, benzarone about 13 hours.

NOTE. For a review of benzbromarone see R. C. Heel *et al.*, *Drugs*, 1977, 14, 349-366.

Dose. Usually 100 mg daily; up to 300 mg daily has been given.

Benzene

Solvent

Synonym. Phenyl Hydride

C_6H_6 = 78.11

CAS—71-43-2

A clear, colourless, mobile, inflammable liquid, with a characteristic aromatic odour, which burns with a smoky flame. B.p. 80°. It solidifies when cooled to 0°.

Practically **immiscible** with water; miscible with dehydrated alcohol, acetone, ether, and glacial acetic acid.

Gas Chromatography. *System GA*—RI 660; *system GI*—retention time 14.8 min.

Ultraviolet Spectrum. Ethanol—255 nm (A_1^1 = 28 b).

Mass Spectrum. Principal peaks at m/z 78, 77, 52, 51, 50, 39, 79, 74.

Quantification. GAS CHROMATOGRAPHY. In blood or tissues: head-space analysis, FID—W. D. Collom and C. L. Winek, *Clin. Toxicol.*, 1970, 3, 125-130. In tissues—C. A. Snyder *et al.*, *Am. ind. Hyg. Ass. J.*, 1977, 38, 272-276. In urine: phenol, detection limit 10 ng/ml, FID—D. L. Rick *et al.*, *J. analyt. Toxicol.*, 1982, 6, 297-300.

Disposition in the Body. Benzene is absorbed from the gastrointestinal tract, through the skin, and from the lungs. About 50% of inhaled benzene is retained in the body; eventually up to 50% of the retained benzene may be eliminated via the lungs, only very small amounts (approximately 0.1%) appearing unchanged in the urine. The remainder of the retained benzene is excreted in the urine, mainly as phenol together with small amounts of catechol and quinol. The excretion of phenol is highest in the first 24 hours and is complete within 48 hours of exposure. The phenolic metabolites are excreted mainly in the conjugated form as ethereal sulphates and glucuronides.

TOXICITY. The maximum permissible atmospheric concentration is 10 ppm or 30 mg/m³. Chronic poisoning may result from exposure to low concentrations over a period of time; 1500 ppm for an hour causes marked depression of the central nervous system and 7500 ppm for half an hour or 20 000 ppm for a few minutes may cause death; chronic inhalation of as little as 100 ppm is likely to cause severe bone marrow depression. The ingestion of 10 ml has caused death.

In a death attributed to inhalation of benzene vapours (glue sniffing), the postmortem concentration of benzene in the blood was 0.94 µg/ml and in the kidney 5.5 µg/g (W. D. Collom and C. L. Winek, *Clin. Toxicol.*, 1970, 3, 125-130).

The following postmortem tissue concentrations were reported in a fatality due to the ingestion of benzene: blood 38 µg/ml, brain 253 µg/g, kidney 21 µg/g, liver 105 µg/g, urine 20 µg/ml (A. Alha *et al.*, *Bull. int. Ass. forens. Toxicol.*, 1975, 11(3), 9).

A 3-year-old child drank some benzene and died 2 hours later; postmortem concentrations were: brain 250 µg/g, kidney 20 µg/g, liver 800 µg/g (A. Heyndrickx *et al.*, *J. Pharm. Belg.*, 1966, 21, 406-408).

HALF-LIFE. Plasma half-life, 9 to 24 hours.

NOTE. For a review of the effects on health of benzene inhalation see T. J. Haley, *Clin. Toxicol.*, 1977, 11, 531-548.

Benzene Hexachloride

Pesticide

Synonyms. BHC; HCH; Hexachlorocyclohexane; Technical Benzene Hexachloride.

$C_6H_6Cl_6$ = 290.8

CAS—319-84-6 (α); 319-85-7 (β); 58-89-9 (γ); 319-86-8 (δ); 6108-10-7 (ϵ)

A mixture of the several isomers of 1,2,3,4,5,6-hexachlorocyclohexane; it contains not less than 12% of the gamma isomer. Benzene hexachloride has five known isomers designated alpha, beta, gamma, delta, and epsilon; of these only the gamma isomer (see Lindane) is outstandingly active as an insecticide.

White to light brown granules, flakes or powder, with a characteristic musty odour. M.p. α 159°, β 312°, γ 112°, δ 138°, ϵ 219°.

Practically **insoluble** in water; its solubility in organic solvents depends on the proportions of the various isomers present.

Gas Chromatography. *System GA*— α -isomer RI 1690, β -isomer RI 1710, δ -isomer RI 1755, γ -isomer RI 1745.

Infra-red Spectrum. Principal peaks at wavenumbers 688, 855, 704, 781, 917, 957 (Nujol mull).

Quantification. See under Lindane.

Disposition in the Body. Absorbed after ingestion, inhalation or through the skin. It is stored in the body fat and adrenal glands. The β -isomer accumulates on chronic exposure (see under Lindane).

TOXICITY. Benzene hexachloride has a greater chronic toxicity than lindane. Ingestion of 20 to 30 g may produce serious toxic effects but death is unlikely unless it is dissolved in an organic solvent.

Benzethonium Chloride

Cationic Disinfectant

Proprietary Names. Hyamine 1622; Phemerol Chloride.

Benzyl dimethyl(2 - {2 - [4 - (1,1,3,3 - tetramethylbutyl)-phenoxy]ethoxy}ethyl)ammonium chloride

$C_{27}H_{42}ClNO_2$ = 448.1

CAS—121-54-0

White crystals. A solution in water foams strongly when shaken. M.p. after drying, 158° to 163°.

Soluble 1 in 0.6 of water, 1 in 0.6 of ethanol, and 1 in 1 of chloroform; slightly soluble in ether; practically insoluble in light petroleum.

Colour Test. Marquis Test—orange.

Thin-layer Chromatography. System TA—Rf 03. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—263 nm, 269 nm ($A_1^1 = 29$ c), 274 nm ($A_1^1 = 28$ c). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1240, 1505, 1120, 826, 1063, 769 (KBr disk).

Use. Used as 0.1 to 0.2% solutions.

Benzhexol

Anticholinergic

Synonym. Trihexyphenidyl

1-Cyclohexyl-1-phenyl-3-piperidinopropan-1-ol

$C_{20}H_{31}NO = 301.5$

CAS—144-11-6

M.p. 114°.

Benzhexol Hydrochloride

Synonyms. Cyclodolum; Trihexyphenidyl Chloride.

Proprietary Names. Anti-Spas; Aparkane; Artane; Artilan; Broflex; Novohegidyl; Parkinane; Peragit; Pipanol; Tremin; Trixyl.

$C_{20}H_{31}NO, HCl = 337.9$

CAS—52-49-3

A white or creamy-white crystalline powder. M.p. about 250°, with decomposition.

Soluble 1 in 100 of water, 1 in 22 of ethanol, 1 in 15 of chloroform, and 1 in 10 of methanol; practically insoluble in ether.

Colour Tests. Mandelin's Test—grey-green; Marquis Test—grey-violet.

Thin-layer Chromatography. System TA—Rf 68; system TB—Rf 65; system TC—Rf 61. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2219.

High Pressure Liquid Chromatography. System HA— k' 1.8.

Ultraviolet Spectrum. Aqueous acid—252 nm ($A_1^1 = 6$ c), 258 nm ($A_1^1 = 7$ c), 264 nm ($A_1^1 = 6$ c).

Infra-red Spectrum. Principal peaks at wavenumbers 702, 756, 973, 1206, 1196, 935 (benzhexol hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 98, 105, 55, 41, 99, 77, 218, 84.

Disposition in the Body. Absorbed after oral administration; disappears rapidly from the tissues.

Toxicity. In some patients, doses of more than 12 mg daily may produce severe mental disturbance and excitement.

The following postmortem concentrations were observed in a 16-year-old youth who experienced hallucinations and was found dead in a nearby lake 2 days after the ingestion of 20 mg of benzhexol: blood 0.03 µg/ml, urine 0.38 µg/ml (L. Kopjak and T. A. Jennison, *Bull. int. Ass. forens. Toxicol.*, 1976, 12(1), 8).

Dose. 1 to 15 mg of benzhexol hydrochloride daily.

Benzilium Bromide

Anticholinergic

Proprietary Names. Portyn; Ulcoban.

3-Benziloyloxy-1,1-diethylpyrrolidinium bromide

$C_{22}H_{28}BrNO_3 = 434.4$

CAS—1050-48-2

A white crystalline powder. M.p. 203° to 204°.

Soluble in water.

Colour Tests. The following tests are performed on benzilium nitrate (see page 128): Liebermann's Test—brown; Marquis Test—orange → green → blue; Sulphuric Acid—orange.

Thin-layer Chromatography. System TA—Rf 03. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm ($A_1^1 = 11$ a), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1728, 1220, 1190, 1162, 690, 1052 (KBr disk).

Quantification. GAS CHROMATOGRAPHY-MASS SPECTROMETRY. In plasma: sensitivity 5 ng/ml—H. Dahlström *et al.*, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 511–513.

Dose. 30 to 70 mg daily.

Benziodarone

Anti-anginal Vasodilator

Proprietary Name. Amplivix

2-Ethylbenzofuran-3-yl 4-hydroxy-3,5-di-iodophenyl ketone

$C_{17}H_{12}I_2O_3 = 518.1$

CAS—68-90-6

A yellowish powder. M.p. 167°.

Soluble 1 in about 500 of water at 25°, and 1 in about 100 of water at 45°; soluble in acetone and chloroform.

Thin-layer Chromatography. System TD—Rf 62; system TE—Rf 23; system TF—Rf 58.

Ultraviolet Spectrum. Methanol—240 nm ($A_1^1 = 1280$ b), 275 nm, 357 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1618, 756, 1577, 1135, 1293, 1176 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 518, 173, 264, 519, 373, 376, 520, 249.

Dose. Benziodarone has been given in initial doses of 600 mg daily and maintenance doses of 300 to 400 mg daily.

Benzocaine

Local Anaesthetic

Synonyms. Anaesthesinum; Anesthamine; Éthoforme; Ethyl Aminobenzoate.

Proprietary Names. Americaine; Anaesthesin. It is an ingredient of AAA, Audicort, Auralgan, Auralgicin, Auraltone, Merocaine, Transvasin, Tyrosolven, and Tyrozets.

Ethyl 4-aminobenzoate

$C_9H_{11}NO_2 = 165.2$

CAS—94-09-7

Colourless crystals or white crystalline powder. M.p. 88° to 92°. **Soluble** 1 in 2500 of water, 1 in 8 of ethanol, 1 in 2 of chloroform, and 1 in 4 of ether; soluble in dilute acids.

Dissociation Constant. pK_a 2.8 (25°).

Colour Test. Diazotisation—red.

Thin-layer Chromatography. *System TA*—Rf 67; *system TB*—Rf 06; *system TC*—Rf 57; *system TD*—Rf 56; *system TE*—Rf 77; *system TF*—Rf 62; *system TL*—Rf 66. (Ninhydrin spray, positive; acidified potassium permanganate solution, positive; Van Urk reagent, bright yellow.)

Gas Chromatography. *System GA*—benzocaine RI 1555, 4-aminobenzoic acid RI 1547; *system GF*—RI 2100.

High Pressure Liquid Chromatography. *System HA*— k' 0.1; *system HQ*— k' 20.06; *system HR*— k' 1.61.

Ultraviolet Spectrum. Aqueous acid—272 nm ($A_1^1 = 90$ c), 278 nm; aqueous alkali—285 nm ($A_1^1 = 930$ a); ethanol—293 nm ($A_1^1 = 1238$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1280, 1680, 1598, 1170, 1315, 1634 (KBr disk).

Mass Spectrum. Principal peaks at m/z 120, 165, 92, 65, 137, 39, 121, 93; 4-aminobenzoic acid 137, 120, 92, 65, 39, 138, 121, 63.

Disposition in the Body. Benzocaine is metabolised by hydrolysis to 4-aminobenzoic acid. At the concentrations normally used (2 to 10%) it is comparatively non-irritant and non-toxic, having only about one-tenth the toxicity of cocaine. The maximum safe amount for topical use is 5000 mg (25 ml of a 20% w/v solution).

Benzoctamine

Tranquilliser

N - (9,10 - Dihydro - 9,10 - ethanoanthracen - 9 - ylmethyl)-methylamine

$C_{18}H_{19}N = 249.4$

CAS—17243-39-9

Benzoctamine Hydrochloride

Proprietary Name. Tacitin(e)

$C_{18}H_{19}N \cdot HCl = 285.8$

CAS—10085-81-1

A white crystalline powder. M.p. about 315°, with decomposition.

Soluble in water, ethanol, and chloroform; sparingly soluble in acetone and ether.

Colour Tests. Mandelin's Test—blue-green; Marquis Test—red-violet.

Thin-layer Chromatography. *System TA*—Rf 59; *system TB*—Rf 57; *system TC*—Rf 52. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2082; *system GF*—RI 2445.

High Pressure Liquid Chromatography. *System HA*— k' 1.7.

Ultraviolet Spectrum. Aqueous acid—264 nm, 271 nm ($A_1^1 = 57$ a). (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 757, 743, 732, 1134, 1060, 1020 (KBr disk).

Mass Spectrum. Principal peaks at m/z 218, 44, 191, 221, 219, 178, 42, 180.

Dose. 30 to 60 mg of benzocaine hydrochloride daily.

Benzoic Acid

Preservative

Synonyms. Benzenecarboxylic Acid; Phenylformic Acid.

Proprietary Names. It is an ingredient of Aserbine and Malatex.

$C_6H_5 \cdot COOH = 122.1$

CAS—65-85-0

Colourless, light feathery crystals or white scales or powder. M.p. 121° to 124° . It sublimes on heating.

Soluble 1 in about 350 of water, 1 in 20 of boiling water, 1 in 3 of ethanol, 1 in 5 of chloroform, and 1 in 3 of ether; freely soluble in acetone.

Sodium Benzoate

$C_6H_5 \cdot CO_2Na = 144.1$

CAS—532-32-1

A white, amorphous, granular, flaky or crystalline powder.

Soluble 1 in 2 of water and 1 in 90 of ethanol.

Dissociation Constant. pK_a 4.2 (25°).

Partition Coefficient. Log P (octanol), 1.9.

Thin-layer Chromatography. *System TD*—Rf 26; *system TE*—Rf 07; *system TF*—Rf 39.

Gas Chromatography. *System GA*—RI 1180.

Ultraviolet Spectrum. Aqueous acid—230 nm ($A_1^1 = 923$ a), 273 nm ($A_1^1 = 85$ a); methanol—227 nm ($A_1^1 = 895$ a), 272 nm ($A_1^1 = 73$ a), 280 nm ($A_1^1 = 61$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 709, 1689, 1296, 667, 935, 685 (KBr disk).

Mass Spectrum. Principal peaks at m/z 105, 77, 51, 122, 50, 39, 74, 76; hippuric acid 105, 135, 51, 134, 77, 106, 50, 78.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 10 ng/ml, ECD—A. Sioufi and F. Pommier, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 161–168.

Disposition in the Body. Benzoic acid is metabolised in the liver by conjugation with glycine and is rapidly and completely excreted in the urine as hippuric acid. Normal urinary excretion of hippuric acid is 1 to 2.5 g daily, equivalent to 0.7 to 1.7 g of

benzoic acid. When taken in large doses, a proportion may be excreted as benzoylglucuronic acid.

Benzoic acid may be found in the urine as a metabolite of benzaldehyde, and is also a metabolite of numerous other compounds.

Uses. Benzoic acid is used as a preservative in a concentration of 0.1%. Sodium benzoate is given by mouth in a dose of 6 g, to test liver function.

Benzonatate

Cough Suppressant

Synonyms. Benzonatine; Benzononatine.

Proprietary Name. Tessalon

3,6,9,12,15,18,21,24,27-Nonaaoctacosyl 4-butylaminobenzoate

$C_{13}H_{18}NO_2(OCH_2CH_2)_nOCH_3$, where n has an average value of 8.

CAS—104-31-4 (where $n = 8$)

A clear, pale yellow, viscous liquid.

Miscible with water, ethanol, chloroform, and ether.

Colour Tests. Aromaticity (Method 2)—yellow/red; Liebermann's Test (at 100°)—blue.

Thin-layer Chromatography. *System TA*—Rf 61. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—not eluted.

Ultraviolet Spectrum. Ethanol—308 nm ($A_1^1 = 473$ c).

Infra-red Spectrum. Principal peaks at wavenumbers 1095, 1605, 1266, 1172, 1698, 1527 (KBr disk).

Mass Spectrum. Principal peaks at m/z 176, 59, 132, 150, 45, 193, 105, 29.

Dose. 300 to 600 mg daily.

Benzoyllecgonine

Alkaloid

Synonym. Ecgonine Benzoate

(1*R*,2*R*,3*S*,5*S*)-2-Carboxytropan-3-yl benzoate

$C_{16}H_{19}NO_4$ = 289.3

CAS—519-09-5

An alkaloid obtained from coca leaves, *Erythroxylum coca* (Erythroxylaceae) and its varieties.

The hydrated form occurs as crystals and melts at 86°. The anhydrous form melts at 195°, with decomposition.

Very **soluble** in hot water; soluble in ethanol; practically insoluble in ether; soluble in dilute acids and alkalis.

Thin-layer Chromatography. System *TA*—Rf 21; system *TB*—Rf 00; system *TC*—Rf 01. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2570.

High Pressure Liquid Chromatography. System *HA*— k' 0.9 (tailing peak); system *HQ*— k' 5.68.

Ultraviolet Spectrum. Aqueous acid—234 nm (A_1^1 = 376 a), 274 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1275, 1720, 1618, 717, 1116, 1316.

Mass Spectrum. Principal peaks at m/z 124, 82, 168, 77, 105, 42, 94, 83.

Quantification. See under Cocaine.

Disposition in the Body. Benzoyllecgonine is the first hydrolysis product formed in the metabolism of cocaine; it is then further hydrolysed to ecgonine.

Benzphetamine

Anorectic

(+)-*N*-Benzyl-*N*α-dimethylphenethylamine

$C_{17}H_{21}N$ = 239.4

CAS—156-08-1

A liquid.

Practically **immiscible** with water; miscible with ethanol, chloroform, and ether.

Benzphetamine Hydrochloride

Proprietary Names. Didrex; Inapétyl.

$C_{17}H_{21}N \cdot HCl$ = 275.8

CAS—5411-22-3

A white crystalline powder. M.p. about 131°.

Freely **soluble** in water, ethanol, and chloroform; slightly soluble in ether.

Dissociation Constant. pK_a 6.6.

Colour Test. Marquis Test—orange.

Thin-layer Chromatography. System *TA*—Rf 73; system *TB*—Rf 67; system *TC*—Rf 70. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, brown.)

Gas Chromatography. System *GA*—benzphetamine RI 1855, amphetamine RI 1123, methylamphetamine RI 1176; system *GB*—benzphetamine RI 1895, amphetamine RI 1134, methylamphetamine RI 1200; system *GC*—benzphetamine RI 2172, amphetamine RI 1536, methylamphetamine RI 1722; system *GF*—benzphetamine RI 2050, amphetamine RI 1315, methylamphetamine RI 1335.

High Pressure Liquid Chromatography. *System HA*—benzphetamine k' 1.2, amphetamine k' 0.9, methylamphetamine k' 2.0; *system HC*—benzphetamine k' 0.15, amphetamine k' 0.98, methylamphetamine k' 2.07.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm ($A_1^1 = 19$ c), 262 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1497, 740, 698, 1028, 1125, 1220 (KBr disk).

Mass Spectrum. Principal peaks at m/z 91, 148, 149, 65, 92, 42, 56, 39.

Quantification. ENZYME IMMUNOASSAY—GAS CHROMATOGRAPHY. In urine: benzphetamine, amphetamine, and methylamphetamine, sensitivity 150 ng/ml for benzphetamine and 50 ng/ml for amphetamine and methylamphetamine—R. D. Budd and N. C. Jain, *J. analyt. Toxicol.*, 1978, 2, 241.

Disposition in the Body. Readily absorbed after oral administration and mainly excreted in the urine as amphetamine and methylamphetamine; very little is excreted as unchanged drug.

Dose. 25 to 150 mg of benzphetamine hydrochloride daily.

Benzquinamide

Anti-emetic

3-Diethylcarbamoyl-1,3,4,6,7,11b-hexahydro-9,10-dimethoxy-2H-benzo[a]quinolizin-2-yl acetate

$C_{22}H_{32}N_2O_5 = 404.5$

CAS—63-12-7

A yellowish crystalline powder. M.p. 130° to 131.5°.

Soluble in dilute acetic acid.

Benzquinamide Hydrochloride

Proprietary Name. Emete-con

$C_{22}H_{32}N_2O_5 \cdot HCl = 441.0$

CAS—113-69-9

Dissociation Constant. pK_a 5.9.

Colour Tests. Liebermann's Test—black; Marquis Test—yellow; Sulphuric Acid—orange.

Thin-layer Chromatography. *System TA*—Rf 65; *system TB*—Rf 07; *system TC*—Rf 69. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. *System HA*— k' 0.3.

Ultraviolet Spectrum. Aqueous acid—282 nm ($A_1^1 = 95$ b). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1244, 1733, 1633, 1204, 1515, 1123 (KBr disk).

Mass Spectrum. Principal peaks at m/z 205, 244, 191, 345, 206, 72, 272, 246.

Quantification. GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma: sensitivity 10 ng/ml—D. C. Hobbs and A. G. Connolly, *J. Pharmacokinet. Biopharm.*, 1978, 6, 477–485.

Disposition in the Body. Readily absorbed after oral administration; bioavailability about 35%. Metabolised by *O*-demethylation, deacetylation and *N*-dealkylation. After an oral dose, up to about 7% is excreted unchanged in the urine in 24 hours.

THERAPEUTIC CONCENTRATION.

Following oral administration of 200 mg to 20 subjects, a mean peak plasma concentration of 0.6 µg/ml was attained in 1.2 hours. Following intramuscular injection of 50 mg to 20 subjects, a mean peak plasma concentration of 0.7 µg/ml was attained in 0.26 hour (D. C. Hobbs and A. G. Connolly, *ibid.*).

HALF-LIFE. Plasma half-life, about 1 hour.

VOLUME OF DISTRIBUTION. About 1 litre/kg.

REFERENCE. D. C. Hobbs and A. G. Connolly, *ibid.*

Dose. The equivalent of 50 mg of benzquinamide by intramuscular injection, repeated as necessary.

Benzthiazide*Diuretic*

Proprietary Names. Aquatag; Exna; Hydrex. It is an ingredient of Decaserpyl Plus and Dytide.

3-Benzylthiomethyl-6-chloro-2*H*-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxide

$C_{15}H_{14}ClN_3O_4S_3 = 431.9$

CAS—91-33-8

A white crystalline powder. M.p. about 240°.

Practically **insoluble** in water, chloroform, and ether; slightly soluble in ethanol; soluble 1 in 100 of acetone; freely soluble in dimethylformamide and in solutions of alkalis.

Colour Tests. Koppányi-Zwicker Test—violet; Liebermann's Test—red-brown; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TD—Rf 14; system TE—Rf 09; system TF—Rf 51.

Gas Chromatography. System GA—RI 2680.

High Pressure Liquid Chromatography. System HN—k' 9.32.

Ultraviolet Spectrum. Aqueous acid—283 nm ($A_1^1 = 292$ a); aqueous alkali—297 nm ($A_1^1 = 310$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1180, 1160, 1310, 1502, 1620, 1590 (KBr disk).

Mass Spectrum. Principal peaks at m/z 91, 121, 65, 122, 309, 64, 230, 123.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma, urine or faeces: sensitivity 10 ng/ml in plasma and 50 ng/ml in urine, UV detection—M. C. Meyer *et al.*, *Biopharm. Drug Disp.*, 1982, 3, 1–9.

Disposition in the Body. Poorly absorbed after oral administration. Less than 10% of a dose is excreted in the urine as unchanged drug in 48 hours, and about 80% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

Following an oral dose of 50 mg to 4 subjects, peak plasma concentrations of about 0.008 and 0.02 µg/ml were attained in 3 hours in 2 subjects; in the remaining 2 subjects benzthiazide was not detectable in the plasma (M. C. Meyer *et al.*, *ibid.*).

HALF-LIFE. Derived from urinary excretion data, about 10 to 15 hours.

REFERENCE. M. C. Meyer *et al.*, *ibid.*

Dose. 50 to 200 mg daily.

Benztropine*Anticholinergic*

Synonym. Benzatropine

(1*R*,3*r*,5*S*)-3-Benzhydryloxytropane

$C_{21}H_{25}NO = 307.4$

CAS—86-13-5

Soluble in chloroform.

Benztrapine Mesylate

Synonyms. Benztrapine Methanesulphonate; Tropine Diphenylmethyl Ether.

Proprietary Names. Bensylate; Cogentin.

$C_{21}H_{25}NO \cdot CH_3SO_3S = 403.5$

CAS—132-17-2

A white, slightly hygroscopic, crystalline powder. M.p. 141° to 145° .

Soluble 1 in 0.7 of water, 1 in 1.5 of ethanol, and 1 in 2 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 10.0 (20°).

Partition Coefficient. Log *P* (heptane), 0.4.

Colour Tests. Mandelin's Test—yellow; Marquis Test—yellow.

Thin-layer Chromatography. *System TA*—Rf 13; *system TB*—Rf 26; *system TC*—Rf 06. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2314.

High Pressure Liquid Chromatography. *System HA*— k' 3.7 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—253 nm, 259 nm ($A_1^1 = 14.5$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1054, 700, 742, 1191, 1204, 1075 (KBr disk).

Mass Spectrum. Principal peaks at m/z 83, 140, 82, 124, 96, 97, 42, 125.

Disposition in the Body. Absorbed after oral administration.

TOXICITY.

In a fatality attributed to the ingestion of an unknown quantity of benztrapine tablets, the following postmortem concentrations were reported: blood 0.7 $\mu\text{g/ml}$, liver 1.6 $\mu\text{g/g}$, urine 0.8 $\mu\text{g/ml}$. In a second case a liver concentration of 2.3 $\mu\text{g/g}$ was found (G. del Villar and M. Liddy, *Bull. int. Ass. forens. Toxicol.*, 1976, 12(2), 11–12).

Dose. 0.5 to 6 mg of benztrapine mesylate daily.

Benzylamine

Analgesic

Synonym. Benzindamine

3-(1-Benzyl-1*H*-indazol-3-yloxy)-*NN*-dimethylpropylamine

$C_{19}H_{23}N_3O = 309.4$

CAS—642-72-8

M.p. 38° to 39° .

Benzylamine Hydrochloride

Proprietary Names. Aflofen; A-Termadol; Diffam; Imotryl; Multum; Tantum; Verax.

$C_{19}H_{23}N_3O \cdot HCl = 345.9$

CAS—132-69-4

A white crystalline powder. M.p. about 159° .

Soluble 1 in 1 of water, 1 in 8 of ethanol, and 1 in 4 of chloroform; practically insoluble in ether.

Colour Test. Mandelin's Test—brown-green.

Thin-layer Chromatography. *System TA*—Rf 44; *system TB*—Rf 36; *system TC*—Rf 22. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2368.

Ultraviolet Spectrum. Aqueous acid—307 nm ($A_1^1 = 144$ c). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1529, 740, 1491, 1613, 1182, 1141 (KBr disk).

Mass Spectrum. Principal peaks at m/z 85, 58, 86, 91, 84, 70, 42, 225.

Quantification. ULTRAVIOLET SPECTROPHOTOMETRY. In plasma or urine—K. Andersson and H. Larsson, *Arzneimittel-Forsch.*, 1974, 24, 1686–1688.

Disposition in the Body. Absorbed after oral administration. About 50% of a dose is excreted unchanged in the urine.

THERAPEUTIC CONCENTRATION.

An oral dose of 1 mg/kg produced a blood concentration of about 0.8 µg/ml within 2 hours and a significant concentration was maintained for several hours (B. Catanese *et al.*, *Arzneimittel-Forsch.*, 1966, 16, 1354–1357).

PROTEIN BINDING. A fraction of benzydamine is bound to proteins in the blood.

REFERENCE. B. Catanese *et al.*, *ibid.*

Dose. 150 to 200 mg of benzydamine hydrochloride daily.

Benzyl Alcohol

Local Anaesthetic/Disinfectant

Synonyms. Phenylcarbinol; Phenylmethanol.

$C_6H_5 \cdot CH_2OH = 108.1$

CAS—100-51-6

A colourless liquid with a faint aromatic odour. Wt per ml 1.043 to 1.046 g. B.p. 203° to 208°.

Soluble 1 in 25 of water; miscible with ethanol, chloroform, and ether.

Gas Chromatography. *System GA—RI 1046.*

Ultraviolet Spectrum. Methanol—252 nm ($A_1^1 = 14$ b), 258 nm ($A_1^1 = 17$ b), 264 nm ($A_1^1 = 13$ b).

Mass Spectrum. Principal peaks at m/z 79, 77, 108, 101, 51, 50, 39, 40.

Use. Topically in concentrations of up to 10%.

Benzyl Benzoate

Acaricide

Proprietary Names. Antiscabiosum Mago; Ascabiol; Benzemul; Scabanca.

$C_6H_5 \cdot CO \cdot O \cdot CH_2 \cdot C_6H_5 = 212.2$

CAS—120-51-4

Colourless crystals or a clear colourless oily liquid. B.p. about 320°.

Practically **insoluble** in water; miscible with ethanol, acetone, carbon disulphide, chloroform, and ether.

Gas Chromatography. *System GA—RI 1738.*

Ultraviolet Spectrum. Ethanol—230 nm ($A_1^1 = 843$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1263, 1706, 1106, 713, 698, 1067 (thin film).

Mass Spectrum. Principal peaks at m/z 77, 105, 91, 51, 65, 212, 50, 78.

Disposition in the Body. Rapidly hydrolysed to benzoic acid and benzyl alcohol; benzyl alcohol then undergoes further oxidation to benzoic acid followed by conjugation with glycine to form hippuric acid. Excreted in the urine mainly as hippuric acid.

Uses. Topically as a 25% application; a 5% solution is used as an insect repellent.

Benzyl Nicotinate

Topical Vasodilator

Proprietary Names. Rubriment. It is an ingredient of Bayolin.

$C_{13}H_{11}NO_2 = 213.2$

CAS—94-44-0

A liquid.

Colour Tests. Cyanogen Bromide—red-orange; Liebermann's Test—brown; Sulphuric Acid—orange.

Thin-layer Chromatography. *System TA—Rf 63; system TB—Rf 42; system TC—Rf 71. (Acidified potassium permanganate solution, positive.)*

Ultraviolet Spectrum. Methanol—262 nm ($A_1^1 = 152$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1278, 1724, 1108, 740, 699, 1587 (KCl disk).

Use. Topically in a concentration of 2.5%.

Benzylmorphine

Narcotic Analgesic/Antitussive

3-O-Benzylmorphine

$C_{24}H_{25}NO_3 = 375.5$

CAS—14297-87-1

A colourless crystalline powder. M.p. 132°.

Soluble 1 in 2500 of water.

Benzylmorphine Hydrochloride

$C_{24}H_{25}NO_3 \cdot HCl = 411.9$

CAS—630-86-4

A colourless microcrystalline powder.

Soluble 1 in 200 of water and 1 in 160 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 8.1 (20°).

Colour Test. Marquis Test—red → violet.

Thin-layer Chromatography. *System TA—Rf 41; system TB—Rf 06; system TC—Rf 23. (Acidified iodoplatinate solution, positive.)*

Gas Chromatography. *System GA—RI 3015.*

High Pressure Liquid Chromatography. *System HC—K 1.03 (tailing peak); system HC—K 1.03.*

Ultraviolet Spectrum. Aqueous acid—284 nm ($A_1^1 = 48$ b). (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1274, 1040, 1502, 1017, 763, 1056.

Mass Spectrum. Principal peaks at m/z 284, 91, 375, 81, 42, 36, 285, 175.

Dose. Benzylmorphine hydrochloride was formerly given in doses of 8 to 30 mg.

Benzylpenicillin

Antibiotic

Synonyms. Crystalline Penicillin G; Penicillin; Penicillin G.

Note. The name 'benzylpenicillin' and its synonyms are commonly used to describe either benzylpenicillin potassium or benzylpenicillin sodium.

(6*R*)-6-(2-Phenylacetamido)penicillanic acid

$C_{16}H_{18}N_2O_4S = 334.4$

CAS—61-33-6

An antimicrobial acid produced by the growth of certain strains of *Penicillium notatum*.

Benzylpenicillin Potassium

Proprietary Names. Abbocillin-G; Crystapen G; Falapen; Hyasorb; M-Cillin B; Megacillin; Novopen; P-50; Paclin G; Pentids; Pfizerpen; Sugracillin.

Note. Megacillin is also used as a proprietary name for clemizole penicillin, phenoxymethylpenicillin, and procaine penicillin.

$C_{16}H_{17}KN_2O_4S = 372.5$

CAS—113-98-4

A white, finely crystalline powder. M.p. 214° to 217°, with decomposition. Very **soluble** in water; soluble in ethanol; practically insoluble in chloroform and ether.

Benzylpenicillin Sodium

Proprietary Names. Crystapen; Gonopen; Spécilline G. It is an ingredient of Bicillin and Triplopen.

Note. Bicillin is also used as a proprietary name for benzathine penicillin.

$C_{16}H_{17}N_2NaO_4S = 356.4$

CAS—69-57-8

A white to slightly yellow, finely crystalline powder.

Very **soluble** in water; soluble in ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 2.8 (25°).

Ultraviolet Spectrum. Benzylpenicillin sodium: water—257 nm ($A_1^1 = 7$ b), 264 nm, 325 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1620, 1777, 1500, 1310, 1700, 703 (benzylpenicillin sodium, KBr disk).

Disposition in the Body. About 30% of an oral dose is absorbed, the remainder being inactivated by gastric acid; maximum concentrations are attained about 1 hour after oral administration. After intramuscular injection it is rapidly absorbed, peak concentrations being attained in 15 to 30 minutes. About 60 to 90% of an intramuscular dose is excreted in the urine, mainly in the first few hours; the urinary material consists of unchanged drug and penicilloic acid (about 20% of the dose). Biliary excretion also occurs.

THERAPEUTIC CONCENTRATION. In plasma, minimum inhibitory concentration 0.006 to 2 µg/ml.

HALF-LIFE. Plasma half-life, about 0.5 to 1 hour; increased in infants, elderly subjects and in renal impairment.

DISTRIBUTION IN BLOOD. Plasma : whole blood ratio, 1.6.

PROTEIN BINDING. In plasma, 45 to 65%.

NOTE. For a review of the pharmacokinetics of penicillin antibiotics see M. Barza and L. Weinstein, *Clin. Pharmacokinet.*, 1976, 1, 297–308.

Dose. 0.6 to 2.4 g daily, given parenterally; up to 24 g daily in severe infections.

Bephenium Hydroxynaphthoate*Anthelmintic**Synonym.* Naphthammonum*Proprietary Name.* Alcopar(a)

Benzyltrimethyl(2-phenoxyethyl)ammonium 3-hydroxy-2-naphthoate

 $C_{28}H_{29}NO_4 = 443.5$ *CAS*—7181-73-9 (bephenium); 3818-50-6 (hydroxynaphthoate)

A yellow to greenish-yellow crystalline powder, which gives a green fluorescence when examined under ultraviolet light. M.p. 168° to 173°, with decomposition.

Practically **insoluble** in water; soluble 1 in 50 of ethanol.

Colour Tests. Mandelin's Test—green; Marquis Test—red-violet.

Thin-layer Chromatography. *System TA*—Rf 77. (*Acidified potassium permanganate solution*, positive.)

Ultraviolet Spectrum. Methanol—234 nm ($A_1^1 = 1300$ b), 263 nm, 270 nm, 283 nm, 295 nm, 352 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1233, 768, 1653, 1590, 858, 726 (KBr disk).

Quantification. COLORIMETRY. In urine—E. W. Rogers, *Br. med. J.*, 1958, 2, 1576–1577.

Disposition in the Body. Poorly absorbed after oral administration; less than 1% of a dose is excreted in the urine in 24 hours.

Dose. The equivalent of 2.5 g of bephenium, as a single dose.

Berberine*Alkaloid*

5,6 - Dihydro - 9,10 - dimethoxybenzo[g] - 1,3 - benzodioxolo[5,6-a]quinolinizinium hydroxide

 $C_{20}H_{19}NO_5 = 353.4$ *CAS*—2086-83-1 ($C_{20}H_{18}NO_4^+$); 117-74-8 ($C_{20}H_{18}NO_4 \cdot OH$)

A quaternary alkaloid present in hydrastis, in various species of *Berberis*, and in many other plants.

Yellow crystals. M.p. 144°.

Soluble 1 in 4.5 of water and 1 in 100 of ethanol; very slightly soluble in ether.

Berberine Hydrochloride*Synonym.* Berberine Chloride $C_{20}H_{18}ClNO_4 \cdot 2H_2O = 407.8$ *CAS*—633-65-8 (anhydrous); 5956-60-5 (dihydrate)

Bright yellow acicular crystals or powder.

Soluble 1 in 400 of water; freely soluble in boiling water; soluble in ethanol; practically insoluble in chloroform and ether.

Berberine Sulphate*Synonyms.* Berberine Acid Sulphate; Berberine Bisulphate. $C_{20}H_{18}NO_4 \cdot HSO_4 = 433.4$ *CAS*—633-66-9

Bright yellow acicular crystals or dark yellow powder.

Soluble 1 in about 150 of water; slightly soluble in ethanol.

Partition Coefficient. Log *P* (octanol), −2.1.

Colour Tests. Mandelin's Test—blue-green → brown; Marquis Test—green.

Thin-layer Chromatography. *System TA*—Rf 07. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2070.

Ultraviolet Spectrum. Aqueous acid—264 nm ($A_1^1 = 554$ b), 345 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1505, 1271, 1234, 1030, 1587, 1098 (KBr disk).

Mass Spectrum. Principal peaks at m/z 321, 278, 320, 292, 306, 191, 322, 304.

Quantification. GAS CHROMATOGRAPHY-MASS SPECTROMETRY. In urine: sensitivity 1 ng/ml—H. Miyazaki *et al.*, *J. Chromat.*, 1978, 152, 79–86.

Disposition in the Body. After oral administration, less than 0.1% of a dose is excreted in the urine unchanged in 24 hours.

Dose. Berberine sulphate has been given in doses of 150 mg daily.

Betahistine

Vasodilator

N-Methyl-2-(2-pyridyl)ethylamine

$C_8H_{12}N_2 = 136.2$

CAS—5638-76-6

A liquid. B.p. about 114°.

Miscible with water, ethanol, chloroform, and ether.

Betahistine Hydrochloride

Proprietary Names. Betaseric; Microser; Serc; Vasomotal.

$C_8H_{12}N_2 \cdot 2HCl = 209.1$

CAS—5579-84-0

A white or creamy-white, hygroscopic, crystalline powder. M.p. about 152°.

Freely soluble in water; soluble in ethanol and methanol; practically insoluble in carbon tetrachloride, chloroform, and ether.

Dissociation Constant. pK_a 3.5, 9.7.

Thin-layer Chromatography. System TA—Rf 10. (Acidified iodoplatinate solution, strong reaction.)

Gas Chromatography. System GA—RI 1235.

High Pressure Liquid Chromatography. System HA— k' 3.1.

Ultraviolet Spectrum. Aqueous acid—261 nm ($A_1^1 = 358$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1585, 1560, 1290, 762, 1238, 1145 (KBr disk).

Mass Spectrum. Principal peaks at m/z 79, 105, 104, 51, 78, 52, 50, 77.

Quantification. GAS CHROMATOGRAPHY. In serum: sensitivity 600 ng/ml, FID—J. F. Douglas and T. L. Hohing, *Experientia*, 1978, 34, 499–500.

Disposition in the Body. Readily absorbed after oral administration; peak plasma concentrations of the metabolites are attained in 3 to 5 hours. Most of a dose is excreted in the urine as metabolites.

Dose. 24 to 48 mg of betahistine hydrochloride daily.

Betaine

Treatment of Hypochlorhydria

Synonyms. Glycine Betaine; Glycocoll Betaine; Lcine; Oxyneurine; Trimethylglycine.

(Carboxymethyl)trimethylammonium hydroxide inner salt

$C_5H_{11}NO_2 = 117.1$

CAS—107-43-7

Deliquescent crystals. M.p. about 310°, with decomposition.

Soluble 1 in 0.6 of water and 1 in 11 of ethanol; sparingly soluble in ether; soluble 1 in 2 of methanol.

Betaine Hydrochloride

Proprietary Names. It is an ingredient of Acidol-Pepsin and Kloreif.

$C_5H_{11}NO_2 \cdot HCl = 153.6$

CAS—590-46-5

Colourless crystals or white crystalline powder. When dissolved in water betaine hydrochloride hydrolyses and almost 25% of its weight of hydrochloric acid is formed. M.p. about 230°, with decomposition.

Soluble 1 in 2 of water and 1 in 20 of ethanol (90%); practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 1.8 (25°).

Colour Test. To an aqueous solution add iodine solution—red precipitate.

Thin-layer Chromatography. System TA—Rf 23. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1731, 1206, 885, 994, 902, 1250 (KBr disk).

Dose. 0.18 to 3.5 g of betaine hydrochloride daily.

Betamethasone

Corticosteroid

Synonyms. Flubenisolone; 9 α -Fluoro-16 β -methylprednisolone.

Proprietary Names. Betnelan; Betnesol; Celeston(e); Desacort-Beta; Minisone; No-Reumar; Pertene.

9 α -Fluoro-11 β ,17 α ,21-trihydroxy-16 β -methylpregna-1,4-diene-3,20-dione

$C_{22}H_{29}FO_5 = 392.5$

CAS—378-44-9

Betamethasone is a synthetic glucocorticoid and an isomer of dexamethasone.

A white to creamy-white crystalline powder. M.p. about 240°, with decomposition. A solution in dioxan is dextrorotatory. Practically **insoluble** in water; soluble 1 in 75 of ethanol, 1 in 15 of warm ethanol, and 1 in 1100 of chloroform; very slightly soluble in ether; sparingly soluble in acetone and methanol.

Betamethasone Acetate

$C_{24}H_{31}FO_6 = 434.5$

CAS—987-24-6

A white to creamy-white powder. M.p. about 165° and, with decomposition, 200° to 220°.

Practically **insoluble** in water; soluble 1 in 9 of ethanol and 1 in 16 of chloroform; freely soluble in acetone.

Betamethasone Benzoate

Proprietary Names. Beben; Benisone; Uticort.

$C_{29}H_{33}FO_6 = 496.6$

CAS—22298-29-9

A white powder. M.p. about 220°, with decomposition.

Practically **insoluble** in water; soluble in ethanol, chloroform, and methanol.

Betamethasone Dipropionate

Proprietary Name. Diprosone

$C_{28}H_{37}FO_7 = 504.6$

CAS—5593-20-4

A white or creamy-white powder. M.p. 170° to 179°, with decomposition. Practically **insoluble** in water; sparingly soluble in ethanol; freely soluble in acetone and chloroform.

Betamethasone Sodium Phosphate

Synonym. Betamethasone Disodium Phosphate

Proprietary Names. Bentelan; Betameson; Betnesol; Celeston(e); Emilan; Paucisone; Vista-Methasone.

$C_{22}H_{28}FNa_2O_8P = 516.4$

CAS—151-73-5

A white hygroscopic powder.

Soluble 1 in 2 of water and 1 in 350 of dehydrated alcohol; freely soluble in methanol; practically insoluble in acetone, chloroform, and ether.

Betamethasone Valerate

Synonym. 9 α -Fluoro-16 β -methylprednisolone 17-Valerate

Proprietary Names. Bedermin; Betacort; Betaderm; Betnelan-V; Betnesol-V; Betneval; Betnovat(e); Bextasol; Celestoderm(-V); Celestone-V; Dermovaleas; Ecoval; Valisone.

$C_{27}H_{37}FO_6 = 476.6$

CAS—2152-44-5

A white to creamy-white powder. M.p. about 190°, with decomposition. Practically **insoluble** in water; soluble 1 in 12 to 1 in 16 of ethanol, 1 in 2 of chloroform, and 1 in 50 of isopropyl alcohol; freely soluble in acetone; slightly soluble in ether.

Note. In alkaline media betamethasone 17-valerate undergoes a rearrangement to betamethasone 21-valerate.

Colour Tests. Antimony Pentachloride—green \rightarrow brown; Naphthol-Sulphuric Acid—green-brown/orange-brown; Sulphuric Acid—pink-orange.

Thin-layer Chromatography. Betamethasone: *system TP*—Rf 30; *system TQ*—Rf 00; *system TR*—Rf 00; *system TS*—Rf 00. (*DPST solution.*) Betamethasone valerate: *system TP*—Rf 58; *system TQ*—Rf 27; *system TR*—Rf 20; *system TS*—Rf 02, streaking may occur. (*DPST solution.*) Betamethasone sodium phosphate remains on the baseline in all systems.

Ultraviolet Spectrum. Betamethasone: ethanol—240 nm ($A_1^1 = 390$ a). Betamethasone sodium phosphate: water—241 nm ($A_1^1 = 296$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1660, 1617, 1606, 1710, 1056, 907 (KBr disk).

Mass Spectrum. Principal peaks at m/z 121, 43, 122, 223, 147, 91, 41, 135.

Dose. 0.5 to 9 mg daily.

Betanaphthol

Parasiticide

Synonyms. β -Naftol; Naphthol.

2-Naphthol

$C_{10}H_8O = 144.2$

CAS—135-19-3

White crystalline leaflets or powder; stable in air but darkens on exposure to light. M.p. 121° to 123°. B.p. 285° to 286°.

Soluble 1 in 1000 of cold water, 1 in 80 of boiling water, 1 in 2 of ethanol, and 1 in 1.5 of ether; soluble in chloroform and in solutions of alkali hydroxides.

Colour Tests. Ferric Chloride—green; Liebermann's Test—green.

To 200 mg add 2 ml of an 8% sodium hydroxide solution and 1 drop of chloroform, then warm—blue.

Ultraviolet Spectrum. Ethanol—274 nm ($A_1^1 = 326$ b), 285 nm ($A_1^1 = 230$ b), 322 nm ($A_1^1 = 120$ b), 330 nm ($A_1^1 = 140$ b).

Disposition in the Body. Rapidly absorbed from the gastrointestinal tract and may be absorbed through intact skin. It is excreted mainly as the glucuronide and gives a reddish tint to the urine.

TOXICITY. The estimated minimum lethal dose is 2 g. Severe nephritis and fatalities have occurred following its absorption through intact skin.

Bethanechol Chloride

Parasympathomimetic

Synonym. Carbamylmethylcholine Chloride

Proprietary Names. Duvoid; Mechothane; Myotonachol; Myotonine Chloride; Urecholine; Urocarb; Vesicholine.

(2-Carbamoyloxypropyl)trimethylammonium chloride

$C_7H_{17}ClN_2O_2 = 196.7$

CAS—674-38-4 (bethanechol); 590-63-6 (chloride)

Colourless or white hygroscopic crystals, or white crystalline powder. There are two crystalline forms, one melts at about 211° and the other at about 219°.

Soluble 1 in 1 of water and 1 in 10 of ethanol, less soluble in dehydrated alcohol; practically insoluble in chloroform and ether.

Thin-layer Chromatography. System TA—Rf 02. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1712, 1014, 1300, 1062, 1094, 946 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 58, 42, 143, 85, 171, 157, 102.

Dose. 15 to 200 mg daily.

Bethanidine

Antihypertensive

Synonym. Betanidine

1-Benzyl-2,3-dimethylguanidine

$\text{C}_{10}\text{H}_{15}\text{N}_3 = 177.2$

CAS—55-73-2

Crystals. M.p. 195° to 197°.

Bethanidine Sulphate

Proprietary Names. Esbaloid; Esbatal; Regulin.

$(\text{C}_{10}\text{H}_{15}\text{N}_3)_2 \cdot \text{H}_2\text{SO}_4 = 452.6$

CAS—114-85-2

A white crystalline powder. M.p. about 280°.

Soluble 1 in 1 of water and 1 in 30 of ethanol; practically insoluble in ether.

Dissociation Constant. pK_a 12 (20°).

Colour Tests. Liebermann's Test—orange → brown; Marquis Test—orange-red.

Thin-layer Chromatography. System TA—Rf 01; system TB—Rf 00; system TC—Rf 00. (Dragendorff spray, positive.)

Gas Chromatography. System GA—RI 1925.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm ($A_1^1 = 11$ a), 264 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1630, 1111, 1174, 701, 1192, 1066 (bethanidine sulphate, KBr disk).

Mass Spectrum. Principal peaks at m/z 71, 91, 106, 177, 57, 72, 65, 30.

Quantification. SPECTROFLUORIMETRY. In plasma: sensitivity 4 ng/ml—C. N. Corder *et al.*, *J. pharm. Sci.*, 1975, 64, 785–788.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma or urine: guanethidine and other guanido-containing drugs, sensitivity 1 ng/ml—J. H. Hengstmann *et al.*, *Analyt. Chem.*, 1974, 46, 34–39.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit 20 ng/ml, UV detection—J. R. Shipe *et al.*, *Clin. Chem.*, 1983, 29, 1793–1795.

Disposition in the Body. Readily but incompletely absorbed after oral administration. It does not appear to be metabolised. After an intravenous dose, about 90% is excreted unchanged in the urine in 3 to 4 days; after an oral dose, 50 to 85% is excreted in the urine and up to about 50% is eliminated in the faeces.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.02 to 0.5 µg/ml.

After a single oral dose of 10 mg to 3 subjects, peak plasma concentrations of about 0.02 to 0.15 µg/ml were attained in 2 hours (C. N. Corder *et al.*, *J. pharm. Sci.*, 1975, 64, 785-788).

After daily oral administration of 30 to 150 mg in divided doses to 12 subjects, steady-state plasma concentrations of 0.02 to 0.5 µg/ml (mean 0.12) were reported (C. N. Corder *et al.*, *J. clin. Pharmacol.*, 1978, 18, 249-258).

HALF-LIFE. The plasma half-life is multiphasic and there is considerable intersubject variation; after intravenous administration, plasma half-lives of about 2 to 6 hours and terminal half-lives of several days have been reported.

PROTEIN BINDING. In plasma, not significantly bound.

Dose. 20 to 200 mg of bethanidine sulphate daily.

Bezafibrate

Lipid Regulating Agent

Proprietary Names. Bezalip; Cedur.

2-[4-(2-*p*-Chlorobenzamidoethyl)phenoxy]-2-methylpropionic acid

$C_{19}H_{20}ClNO_4 = 361.8$

CAS—41859-67-0

An off-white crystalline powder. M.p. 183° to 186°.

Practically **insoluble** in water; slightly soluble in ethanol, acetone, and methanol; soluble in dimethylformamide.

Ultraviolet Spectrum. Methanol—230 nm ($A_1^1 = 644$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1715, 1540, 1610, 1140, 1500, 1220 (KBr disk).

Dose. 400 to 600 mg daily.

Bezitramide

Narcotic Analgesic

Synonym. Burgodin

4-[4-(2,3-Dihydro-2-oxo-3-propionyl-1*H*-benzimidazol-1-yl)piperidino]-2,2-diphenylbutyronitrile

$C_{31}H_{32}N_4O_2 = 492.6$

CAS—15301-48-1

A white, amorphous or crystalline powder. M.p. 145° to 149°.

Practically **insoluble** in water and ethanol; soluble 1 in 45 of acetone, 1 in 2 of chloroform, and 1 in 400 of ether.

Colour Test. Mandelin's Test—violet → orange.

Thin-layer Chromatography. System *TA*—Rf 71; system *TB*—Rf 41; system *TC*—Rf 79. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. System *HA*— k' 0.2.

Ultraviolet Spectrum. After solution in chloroform and dilution with acid isopropyl alcohol—251 nm ($A_1^1 = 118$ b), inflexion at 274 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1733, 755, 1708, 700, 1286, 1054 (KBr disk).

Mass Spectrum. Principal peaks at m/z 286, 300, 96, 42, 244, 230, 301, 82.

Quantification. GAS CHROMATOGRAPHY. In urine: 3-cyano-3,3-diphenylpropionic acid, sensitivity 600 ng/ml, AFID—H. H. van Rooy *et al.*, *J. Chromat.*, 1978, 148, 447-452.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In urine: 1,3-dihydro-1-(piperidin-4-yl)benzimidazol-2-one, sensitivity 150 ng/ml, UV detection—H. H. van Rooy and C. Soe-Agnie, *J. Chromat.*, 1978, 156, 189-195.

Disposition in the Body. Absorbed after oral administration. It is metabolised by hydrolysis to 3-cyano-3,3-diphenylpropionic acid and 1,3-dihydro-1-(piperidin-4-yl)benzimidazol-2-one which are excreted in the urine.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 5 mg to 7 subjects, peak plasma concentrations (bezitramide plus major metabolite) of about 0.005 µg/ml were attained in about 3 hours; in 3 of the subjects, plasma concentrations remained fairly constant over a period of 7 hours; in a further 2 subjects, distinct secondary peak plasma concentrations were observed (D. K. F. Meijer *et al.*, *Eur. J. clin. Pharmacol.*, 1984, 27, 615-618).

Dose. Bezitramide has been given in doses of 5 mg; maximum of 30 mg in 24 hours.

Bialamicol

Anti-amoebic

Synonyms. Biallylamicol; Biethylamicol.

3,3'-Diallyl-5,5'-bis(diethylaminomethyl)biphenyl-4,4'-diol

$C_{28}H_{40}N_2O_2 = 436.6$

CAS—493-75-4

Bialamicol Hydrochloride

Proprietary Name. Camoform

$C_{28}H_{40}N_2O_2 \cdot 2HCl = 509.6$

CAS—3624-96-2

A white crystalline powder. M.p. about 210°.

Soluble 1 in 5 of water, 1 in 40 of ethanol, and 1 in 150 of chloroform; slightly soluble in ether.

Colour Tests. Folin-Ciocalteu Reagent—blue; Liebermann's Test—green.

Dissolve 100 mg in 2 ml of water and add 2 ml of *nitric acid*—intense orange-red.

Thin-layer Chromatography. System *TA*—Rf 74; system *TB*—Rf 62; system *TC*—Rf 80.

Ultraviolet Spectrum. Aqueous acid—266 nm ($A_1^1 = 440$ a).

Mass Spectrum. Principal peaks at m/z 58, 30, 363, 44, 72, 29, 27, 364.

Disposition in the Body. Rapidly absorbed from the gastrointestinal tract and stored in high concentrations in the liver, lungs and tissues. Slowly excreted in the bile and eliminated in the faeces.

Dose. Bialamilcol hydrochloride has been given in doses of 0.75 to 1.5 g daily.

Bibenzonium Bromide

Cough Suppressant

Synonym. Diphenetholine Bromide

Proprietary Name. Lysobex

[2-(1,2-Diphenylethoxy)ethyl]trimethylammonium bromide

$C_{19}H_{26}BrNO = 364.3$

CAS—59866-76-1 (bibenzonium); 15585-70-3 (bromide)

Crystals. M.p. 142° to 144°.

Very **soluble** in water and ethanol; practically insoluble in ether.

Colour Tests. The following tests are performed on bibenzonium nitrate (see page 128): Mandelin's Test—green; Marquis Test—brown.

Thin-layer Chromatography. System *TA*—Rf 02. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 1923.

Ultraviolet Spectrum. Aqueous acid—253 nm, 258 nm ($A_1^1 = 11.4$ b), 264 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 705, 1095, 749, 759, 1020, 952 (KBr disk).

Dose. 40 to 120 mg daily.

Biperiden

Anticholinergic

1-(Bicyclo[2.2.1]hept-5-en-2-yl)-1-phenyl-3-piperidinopropan-1-ol

$C_{21}H_{29}NO = 311.5$

CAS—514-65-8

A white crystalline powder. M.p. 112° to 116°.

Practically **insoluble** in water; soluble 1 in 75 of ethanol, 1 in 2 of chloroform, and 1 in 14 of ether.

Biperiden Hydrochloride

Proprietary Names. Akineton (tablets); Akinophyl.

$C_{21}H_{29}NO \cdot HCl = 347.9$

CAS—1235-82-1

A white crystalline powder. M.p. about 275°, with decomposition.

Slightly **soluble** in water, ethanol, chloroform, and ether; sparingly soluble in methanol.

Biperiden Lactate

Proprietary Name. Akineton (injection)

$C_{21}H_{29}NO \cdot C_3H_5O_3 = 401.5$

CAS—7085-45-2

Colour Tests. Liebermann's Test—brown; Marquis Test—red-brown; Sulphuric Acid—orange-brown.

Thin-layer Chromatography. System *TA*—Rf 64; system *TB*—Rf 68; system *TC*—Rf 64. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2266.

Ultraviolet Spectrum. Aqueous acid—252 nm, 259 nm ($A_1^1 = 5.6$ b), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 702, 735, 1121, 997, 760, 1153 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 98, 218, 99, 55, 41, 42, 77, 84.

Quantification. GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In plasma: sensitivity 250 pg/ml, AFID-Th. Le Bris and E. Brode, *Arzneimittel-Forsch.*, 1985, 35, 149–151.

Disposition in the Body. Rapidly absorbed after oral administration.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 4 mg to 6 subjects, peak plasma concentrations of 0.004 to 0.006 $\mu\text{g/ml}$ were attained in 1.5 hours (M. Hollman *et al.*, *Eur. J. clin. Pharmac.*, 1984, 27, 619–621).

HALF-LIFE. Plasma half-life, about 18 hours.

Dose. 2 to 12 mg of biperiden hydrochloride daily, by mouth. Biperiden lactate is given parenterally in doses of 5 to 20 mg daily.

Bisacodyl

Purgative

Proprietary Names. Bisacolax; Biscolax; Contlax; Deficol; Delco-Lax; Dulcolax; Laco; Laxbene; Perilax; Theralax; Toilax. It is an ingredient of Dulcodos.

4,4'-(2-Pyridylmethylene)di(phenyl acetate)

$\text{C}_{22}\text{H}_{19}\text{NO}_4 = 361.4$

CAS—603-50-9

A white crystalline powder. M.p. 131° to 135°.

Very slightly **soluble** in water; soluble 1 in 100 of ethanol, 1 in 35 of chloroform, and 1 in 170 of ether; sparingly soluble in methanol; soluble in dilute acids.

Colour Tests. Liebermann's Test—red-brown; Mandelin's Test—violet; Marquis Test—violet.

Thin-layer Chromatography. System *TA*—Rf 74; system *TB*—Rf 15; system *TC*—Rf 76. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2820.

Ultraviolet Spectrum. Aqueous acid—264 nm ($A_1^1 = 270$ a); methanolic potassium hydroxide—248 nm ($A_1^1 = 650$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1212, 1198, 1754, 1162, 1500, 909 (KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 361, 277, 319, 276, 199, 318, 362, 43.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In urine: bisacodyl diphenol, sensitivity 1 $\mu\text{g/ml}$, UV detection—L. Loof *et al.*, *Ther. Drug Monit.*, 1980, 2, 345–349.

THIN-LAYER CHROMATOGRAPHY-COLORIMETRY. In urine: bisacodyl diphenol—R. Jauch *et al.*, *Arzneimittel-Forsch.*, 1975, 25, 1796–1800.

Disposition in the Body. Variably absorbed after oral administration and metabolised by deacetylation to the active metabolite, bis(4-hydroxyphenyl)-2-pyridylmethane (bisacodyl diphenol). Up to about 30% of a dose is excreted in the urine in 48 hours as bisacodyl diphenol glucuronide; about 50% of a dose is eliminated in the faeces as unconjugated bisacodyl diphenol.

Dose. 5 to 10 mg daily.

Bitoscanate

Anthelmintic

Phenylene-1,4-bis(isothiocyanate)
 $C_8H_4N_2S_2 = 192.3$
CAS—4044-65-9

A yellowish-white crystalline powder. M.p. 130° to 132°. Practically **insoluble** in water; soluble in ethanol, chloroform, and ether.

Colour Tests. Mandelin's Test—brown-violet; Palladium Chloride—orange.

Thin-layer Chromatography. *System TA*—Rf 65. (*Acidified potassium permanganate solution*, positive.)

Ultraviolet Spectrum. Ethanol—296 nm, 311 nm ($A_1^1 = 1795$ a).

Disposition in the Body. Partly absorbed after oral administration. About 28% of a dose is excreted in the urine in 30 days and 55% is eliminated in the faeces, mainly in the first week.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 100 mg of ^{14}C -labelled bitoscanate to 6 subjects, peak blood concentrations of total radioactivity equivalent to 0.58 to 2.1 $\mu g/ml$ (mean 1.4) of bitoscanate were reported at about 24 hours (O. E. Christ *et al.*, *Arzneimittel-Forsch.*, 1970, 20, 756–762).

HALF-LIFE. Plasma half-life (total radioactivity), about 26 hours.

REFERENCE. O. E. Christ *et al.*, *ibid.*

Dose. 100 mg at 12-hourly intervals for 3 doses.

Brallobarbitone

Barbiturate

Synonym. Brallobarbitol

Proprietary Name. It is an ingredient of Vesparax.

5-Allyl-5-(2-bromoallyl)barbituric acid

$C_{10}H_{11}BrN_2O_3 = 287.1$

CAS—561-86-4

M.p. 168° to 169°.

Colour Test. Vanillin Reagent—brown-orange/brown-orange.

Thin-layer Chromatography. *System TD*—Rf 52; *system TE*—Rf 30; *system TF*—Rf 69; *system TH*—Rf 47.

Gas Chromatography. *System GA*—brallobarbitone RI 1858, 5-acetonyl-5-allylbarbituric acid RI 1795; *system GF*—RI 2765.

High Pressure Liquid Chromatography. *System HG*— k' 3.09; *system HH*— k' 1.72.

Ultraviolet Spectrum. *Borax buffer 0.05M* (pH 9.2)—240 nm ($A_1^1 = 304$ b); *M sodium hydroxide* (pH 13)—256 nm ($A_1^1 = 236$ b).

Mass Spectrum. Principal peaks at m/z 207, 41, 39, 124, 91, 165, 122, 44.

Quantification. See under Amylobarbitone.

Disposition in the Body. Absorbed after oral administration. About 5% of a dose is excreted in the urine as unchanged drug, 9% as 5-acetonyl-5-allylbarbituric acid and less than 1% each as 5-acetonyl-5-(2-bromoallyl)barbituric acid and 5-allyl-5-(2-hydroxypropyl)barbituric acid.

Ultraviolet Spectrum. Aqueous acid—263 nm, 272 nm ($A_1^1 = 22$ a), 278 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1188, 1012, 1032, 1120, 680, 815 (KBr disk).

TOXICITY.

In 10 fatalities involving the ingestion of a preparation containing brallobarbitone, quinalbarbitone and hydroxyzine, the following post-mortem concentrations, $\mu\text{g/g}$ (mean, n) were reported:

	Brallobarbitone	Quinalbarbitone
Blood	9.8–25 (16.3, 9)	10–33.4 (17.7, 9)
Brain	1.9–24.1 (12.7, 10)	8.6–50 (29.3, 10)
Kidney	8.9–28.1 (20.4, 10)	14.5–83.4 (30.6, 10)
Liver	14.9–241 (50.2, 10)	23.1–231 (95.7, 10)
Urine	1.8–201 (40.8, 6)	1.0–7.1 (4.0, 6)

(G. Sticht and H. Kaferstein, *Z. Rechtsmed.*, 1980, 85, 169–175).

In an overdose involving the ingestion of more than 3 g of brallobarbitone (in combination with quinalbarbitone), plasma concentrations of 106 $\mu\text{g/ml}$ of brallobarbitone and 57 $\mu\text{g/ml}$ of quinalbarbitone were reported 6 hours and 4 hours, respectively, after ingestion; the subject slowly recovered after treatment by haemoperfusion (G. de Groot *et al.*, *Vet. Hum. Toxicol.*, 1979, 21, 8–11).

Bretylum Tosylate

Anti-arrhythmic/Antihypertensive

Synonym. Bretylum Tosilate

Proprietary Names. Bretylate; Bretylol.

(2-Bromobenzyl)ethyltrimethylammonium toluene-4-sulphonate

$\text{C}_{11}\text{H}_{17}\text{BrN}, \text{C}_7\text{H}_7\text{O}_3\text{S} = 414.4$

CAS—59-41-6 (bretylum); 61-75-6 (tosylate).

A white crystalline powder. M.p. about 98°.

Soluble 1 in 1 of water and 1 in 0.4 of ethanol; practically insoluble in ether.

Thin-layer Chromatography. System TA—Rf 01; system TN—Rf 94; system TO—Rf 40. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. System HA—k' 4.3 (tailing peak).

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 5 ng/ml, ECD—C.-M. Lai *et al.*, *J. pharm. Sci.*, 1980, 69, 681–683. In plasma, urine or myocardial tissue: sensitivity 1 ng/ml, ECD—E. Patterson *et al.*, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 33–39.

Disposition in the Body. Poorly absorbed after oral administration; bioavailability about 25%. Excreted mainly in the urine as unchanged drug but a high proportion of bretylum is also excreted into the bile. After intravenous infusion about 70% of the dose is excreted in the urine in 24 hours and 90% in 48 hours. After chronic oral dosing about 20% of a dose is excreted in the 24-hour urine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 5 mg/kg to 10 subjects, peak serum concentrations of 0.04 to 0.14 $\mu\text{g/ml}$ (mean 0.08) were attained in 1 to 8

hours; following intravenous infusion of 5 mg/kg over 30 minutes to the same subjects, serum concentrations at the end of the infusion were reported to be in the range 1.1 to 2.4 µg/ml (mean 1.9) (J. L. Anderson *et al.*, *Clin. Pharmac. Ther.*, 1980, 28, 468–478).

HALF-LIFE. Plasma half-life, about 7 to 10 hours, increased in renal impairment.

VOLUME OF DISTRIBUTION. About 8 litres/kg.

CLEARANCE. Plasma clearance, about 11 ml/min/kg.

PROTEIN BINDING. In plasma, not significantly bound.

NOTE. For further information on bretylium tosylate see E. R. Garrett *et al.*, *Biopharm. Drug Disp.*, 1982, 3, 129–164.

Dose. 5 to 10 mg/kg by intramuscular injection. Bretylium tosylate has been given by mouth in doses of 0.3 to 1.2 g daily.

Bromazepam

Tranquilliser

Proprietary Names. Lexotan; Lexotanil.

7-Bromo-1,3-dihydro-5-(2-pyridyl)-2H-1,4-benzodiazepin-2-one

C₁₄H₁₀BrN₃O = 316.2

CAS—1812-30-2

A pale yellow crystalline solid. M.p. about 247°.

Dissociation Constant. pK_a 2.9, 11.0.

Partition Coefficient. Log P (octanol/pH 7.4), 1.6.

Colour Test. Formaldehyde–Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 61; system TB—Rf 12; system TC—Rf 41; system TD—Rf 13; system TE—Rf 62; system TF—Rf 20.

Gas Chromatography. System GA—bromazepam RI 2663, 3-hydroxybromazepam RI 2537; system GG—RI 3280.

High Pressure Liquid Chromatography. System HI—k' 2.32; system HK—k' 2.99.

Ultraviolet Spectrum. Aqueous acid—239 nm, 345 nm; aqueous alkali—237 nm (A₁¹ = 920 b), 348 nm; methanol—233 nm (A₁¹ = 1050 b), 320 nm (A₁¹ = 61 b).

Infra-red Spectrum. Principal peaks at wavenumbers 1685, 825, 750, 802, 1315, 1230.

Mass Spectrum. Principal peaks at m/z 236, 317, 315, 288, 316, 286, 208, 78; 3-hydroxybromazepam 79, 78, 52, 105, 304, 314, 316, 51.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 5 ng/ml, ECD—U. Klotz, *J. Chromat.*, 1981, 222; *Biomed. Appl.*, 11, 501–506.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 5 ng/ml, UV detection—H. Hirayama *et al.*, *J. Chromat.*, 1983, 277; *Biomed. Appl.*, 28, 414–418.

Disposition in the Body. Well absorbed after oral administration. About 70% of a dose is excreted in the urine in 72 hours, including about 2% of the dose as unchanged bromazepam, about 28% as the glucuronide of 3-hydroxybromazepam, about

39% as the glucuronide of 2-amino-3-hydroxy-5-bromobenzoylpyridine, and less than 1% as 2-(2-amino-5-bromobenzoyl)pyridine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 12 mg, administered to 10 subjects, peak plasma concentrations of 0.11 to 0.17 µg/ml (mean 0.13) were attained in 1 to 4 hours. Steady-state concentrations of 0.08 to 0.15 µg/ml (mean 0.12) were measured during dosing of 6 subjects with 9 mg daily (S. A. Kaplan *et al.*, *J. Pharmacokinet. Biopharm.*, 1976, 4, 1–16).

HALF-LIFE. Plasma half-life, 8 to 19 hours (mean 12).

VOLUME OF DISTRIBUTION. About 0.9 litre/kg.

PROTEIN BINDING. In plasma, 40 to 70%.

Dose. Usually 6 to 9 mg daily; up to 36 mg daily has been given.

Bromhexine*Mucolytic Expectorant**N*-(2-Amino-3,5-dibromobenzyl)-*N*-cyclohexylmethylamine $C_{14}H_{20}Br_2N_2 = 376.1$

CAS—3572-43-8

**Bromhexine Hydrochloride***Proprietary Names.* Bisolvon; Broncokin; Dakryo Biciron; Ophthosol. It is an ingredient of Alupent Expectorant and Bisolvomycin. $C_{14}H_{20}Br_2N_2 \cdot HCl = 412.6$

CAS—611-75-6

A white crystalline powder. M.p. about 235°.

Soluble 1 in 250 of water, 1 in 100 of ethanol, 1 in 300 of chloroform, and 1 in 50 of methanol; practically insoluble in acetone; soluble in glacial acetic acid.**Thin-layer Chromatography.** *System TA*—Rf 75; *system TB*—Rf 67; *system TC*—Rf 79. (*Acidified iodoplatinate solution*, positive.)**Gas Chromatography.** *System GA*—RI 2337.**High Pressure Liquid Chromatography.** *System HA*— k' 0.4.**Ultraviolet Spectrum.** Aqueous acid—245 nm ($A_1^1 = 259$ a), 310 nm; aqueous alkali—262 nm, 317 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1602, 1031, 1074, 1548, 1122, 857 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 70, 112, 293, 264, 44, 42, 305, 41.**Quantification.** GAS CHROMATOGRAPHY. In plasma: sensitivity 1 ng/ml, ECD—A. P. DeLeenheer and L. M. R. Vandecasteele-Thienpont, *J. pharm. Sci.*, 1980, 69, 99–100.

Wavelength

**HIGH PRESSURE LIQUID CHROMATOGRAPHY.** In plasma or urine: detection limit 4 ng/ml in plasma and 2 ng/ml in urine, UV detection—E. Bechgaard and A. Nielsen, *J. Chromat.*, 1982, 228; *Biomed. Appl.*, 17, 392–397.**Disposition in the Body.** Well absorbed after oral administration but undergoes considerable first-pass metabolism including conjugation with glucuronic acid or sulphate; ambroxol, *trans*-4-(2-amino-3,5-dibromobenzylamino)cyclohexanol, is an active metabolite of bromhexine. About 70% of an oral dose is excreted in the urine in 24 hours as metabolites with less than 1% as unchanged drug.**THERAPEUTIC CONCENTRATION.**Following single oral doses of 32 mg to 10 subjects, peak plasma concentrations of 0.01 to 0.14 μ g/ml (mean 0.04) were attained in 0.5 to 2.5 hours (E. Bechgaard and A. Nielsen, *Biopharm. Drug Disp.*, 1982, 3, 337–344).**HALF-LIFE.** Derived from plasma and urinary data, about 6 hours.**REFERENCE.** E. Bechgaard and A. Nielsen, *ibid.***Dose.** 24 to 64 mg of bromhexine hydrochloride daily.**Bromocriptine***Dopaminergic Agent**Synonyms.* 2-Bromo- α -ergocryptine; Bromocryptine; 2-Bromoergocryptine.2-Bromo-12'-hydroxy-5' α -isobutyl-2'-isopropylergotaman-3',6',18-trione $C_{32}H_{40}BrN_5O_5 = 654.6$

CAS—25614-03-3

Crystals. M.p. 215° to 218°, with decomposition.

Bromocriptine Mesylate

Synonym. Bromocriptine Methanesulphonate

Proprietary Names. Parlodel; Pravidel.

$C_{32}H_{40}BrN_5O_5 \cdot CH_4O_3S = 750.7$

CAS—22260-51-1

A yellowish-white crystalline powder. M.p. 192° to 196°, with decomposition.

Thin-layer Chromatography. *System TA*—Rf 72; *system TB*—Rf 00; *system TC*—Rf 69.

High Pressure Liquid Chromatography. *System HP*— k' 44.3.

Ultraviolet Spectrum. Aqueous acid—306 nm ($A_1^1 = 138$ b); aqueous alkali—239 nm ($A_1^1 = 373$ b), 300 nm ($A_1^1 = 144$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1170, 1633, 1217, 1660, 1715, 1045 (bromocriptine mesylate).

Mass Spectrum. Principal peaks at m/z 70, 43, 154, 71, 41, 209, 86, 195.

Quantification. GAS CHROMATOGRAPHY. In plasma: comparison with GC-MS and HPLC, sensitivity 500 pg/ml for GC and 1 ng/ml for GC-MS and HPLC—N. E. Larsen *et al.*, *J. Chromat.*, 1979, 174, 341–349.

RADIOIMMUNOASSAY. In plasma: sensitivity 100 pg/ml—H. F. Schran *et al.*, *Clin. Chem.*, 1979, 25, 1928–1933.

Disposition in the Body. Rapidly absorbed after oral administration. It undergoes extensive first-pass metabolism by hydrolysis and isomerisation to 2-bromolysergic acid and 2-bromoisolysergic acid, and by hydroxylation, further oxidation and conjugation to produce a large number of metabolites. About 7% of a dose is excreted in the urine as metabolites together with a small fraction as unchanged drug. About 70% of a dose is eliminated in the faeces via the bile within 5 days of a single oral dose.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 25 mg to 9 subjects, peak plasma concentrations of 0.001 to 0.004 µg/ml were attained in about 90 minutes; after single doses of 50 and 100 mg to 7 and 5 subjects, respectively, peak plasma concentrations of 0.003 to 0.020 µg/ml (mean 0.01) and 0.006 to 0.025 µg/ml (mean 0.01) were attained in about 90 to 120 minutes (P. Price *et al.*, *Br. J. clin. Pharmac.*, 1978, 6, 303–309).

Following daily oral administration of 60 to 150 mg in divided doses to 4 subjects, minimum steady-state plasma concentrations of 0.009 to 0.054 µg/ml (mean 0.03) and saliva concentrations of 0.0001 to 0.0004 µg/ml were reported (M. L. Friis *et al.*, *Eur. J. clin. Pharmac.*, 1980, 18, 171–174).

HALF-LIFE. Plasma half-life, about 3 hours.

VOLUME OF DISTRIBUTION. About 3 litres/kg.

PROTEIN BINDING. In plasma, 90 to 96%.

Dose. The equivalent of 1.25 to 30 mg of bromocriptine daily. In parkinsonism, the usual maintenance dose is the equivalent of 40 to 100 mg daily, but up to 300 mg daily has been given.

Bromodiphenhydramine

Antihistamine

Synonyms. Bromazine; Bromdiphenhydramine; Histabromamine.

2-(4-Bromobenzhydryloxy)-*NN*-dimethylethylamine

$C_{17}H_{20}BrNO = 334.3$

CAS—118-23-0

**Bromodiphenhydramine Hydrochloride**

Proprietary Name. Ambodryl

$C_{17}H_{20}BrNO \cdot HCl = 370.7$

CAS—1808-12-4

A white to pale buff-coloured crystalline powder. M.p. 148° to 152°.

Soluble 1 in less than 1 of water, 1 in 2 of ethanol, 1 in 2 of chloroform, and 1 in 31 of isopropyl alcohol; practically insoluble in ether.

Dissociation Constant. pK_a 8.6 (25°).

Colour Test. Marquis Test—yellow.

Thin-layer Chromatography. *System TA*—Rf 54; *system TB*—Rf 44; *system TC*—Rf 43. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *Marquis reagent*, yellow.)

Gas Chromatography. *System GA*—RI 2155; *system GF*—RI 2480.

High Pressure Liquid Chromatography. *System HA*— k' 2.7.

Ultraviolet Spectrum. Aqueous acid—230 nm ($A_1^1 = 465$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1067, 1094, 1007, 696, 1041, 746 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 73, 45, 165, 59, 42, 166, 149.

Disposition in the Body. Absorbed after oral administration. A number of metabolites have been identified in the urine including the *N*-oxide, monodesmethyl and didesmethyl derivatives, 4-bromobenzhydrol, 4-bromobenzophenone, and 4-hydroxybenzophenone; glucuronide conjugates of some of these metabolites have also been reported. Unchanged drug is also excreted in the urine.

Dose. 75 to 100 mg of bromodiphenhydramine hydrochloride daily.

Brompheniramine

Antihistamine

Synonym. Parabromdylamine

(\pm)-3-(4-Bromophenyl)-*NN*-dimethyl-3-(2-pyridyl)propylamine

$C_{16}H_{19}BrN_2 = 319.2$

CAS—86-22-6

A slightly yellow, oily liquid.

Miscible with dilute acids.

Brompheniramine Maleate

Proprietary Names. Antial; Dimegan; Dimetane; Dimotane; Drauxin; Ebalin; Gammistin; Ilvin; Veltane. It is an ingredient of Dimotapp and Exyphen.

$C_{16}H_{19}BrN_2 \cdot C_4H_4O_4 = 435.3$

CAS—980-71-2; 32865-01-3 (\pm)

A white crystalline powder. M.p. 130° to 135°.

Soluble 1 in 5 of water, 1 in 15 of ethanol, and 1 in 15 of chloroform; slightly soluble in ether.

Dissociation Constant. pK_a 3.9, 9.2.

Colour Test. Cyanogen Bromide—orange.

Thin-layer Chromatography. System *TA*—Rf 45; system *TB*—Rf 33; system *TC*—Rf 16. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2096; system *GB*—RI 2159; system *GC*—RI 2457; system *GF*—RI 2470.

High Pressure Liquid Chromatography. System *HA*— k' 4.1.

Ultraviolet Spectrum. Aqueous acid—265 nm ($A_1^1 = 272$ a); aqueous alkali—262 nm ($A_1^1 = 177$ a), 269 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1585, 750, 1003, 1067, 1565, 1040 (KBr disk).

Mass Spectrum. Principal peaks at m/z 247, 249, 58, 72, 248, 167, 250, 168.

Quantification. GAS CHROMATOGRAPHY. In blood or urine: sensitivity 10 ng/ml in blood, ECD—R. B. Bruce *et al.*, *Analyt. Chem.*, 1968, 40, 1246–1250.

Disposition in the Body. Absorbed after oral administration; accumulates in the body during chronic daily dosing. The main metabolic reactions are *N*-demethylation and deamination. About 50% of a ^{14}C -labelled dose is excreted in the urine in 5 days, with 10% of the dose as unchanged brompheniramine, 11% as monodesmethylbrompheniramine, 10% as didesmethylbrompheniramine, 4% as 3-(4-bromophenyl)-3-(2-pyridyl)-propionic acid, and 2% as its glycine conjugate; other unidentified polar metabolites are also present. Less than 3% of the dose is eliminated in the faeces. Under steady-state conditions the daily excretion rate appears to be dependent on urinary pH and volume.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 8 mg administered to 2 subjects, peak blood concentrations of 0.012 and 0.017 $\mu\text{g}/\text{ml}$ were attained in 3 hours (R. B. Bruce *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, about 15 hours.

Dose. 12 to 32 mg of brompheniramine maleate daily.

Bromvaletone

Hypnotic/Sedative

Synonyms. Bromisoval; Bromisovalerylurea; Bromisovalum; Bromvalerylurea; Bromylum.

Proprietary Name. Bromural

N-(2-Bromo-3-methylbutyl)urea

$\text{C}_6\text{H}_{11}\text{BrN}_2\text{O}_2 = 223.1$

CAS—496-67-3

Small, white, acicular or scale-like crystals, which sublime on heating. M.p. about 150°.

Soluble 1 in 500 of water, 1 in 15 of ethanol, 1 in 6 of chloroform, and 1 in 25 of ether; soluble in solutions of alkali hydroxides.

Dissociation Constant. pK_a 10.8.

Colour Test. Nessler's Reagent—brown-orange.

Ultraviolet Spectrum. Aqueous alkali—233 nm ($A_1^1 = 160$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1720, 1700, 1581, 1210, 1170, 1300 (KBr disk). Polymorphism may occur.

Mass Spectrum. Principal peaks at m/z 44, 83, 180, 182, 137, 143, 139, 41.

Quantification. GAS CHROMATOGRAPHY. In biological fluids and tissues: sensitivity 200 ng/ml, FID—L. R. Goldbaum and T. J. Domanski, *J. forens. Sci.*, 1966, 11, 233–242.

Dose. Bromvaletone has been given in doses of 300 to 900 mg.

Broxaldine

Antiprotozoal

Synonym. Brobenzoxaldine

Proprietary Name. It is an ingredient of Intestopan.

5,7-Dibromo-2-methyl-8-quinolyl benzoate

$\text{C}_{17}\text{H}_{11}\text{Br}_2\text{NO}_2 = 421.1$

CAS—3684-46-6

An off-white powder.

Practically **insoluble** in water; soluble in ether.

Colour Tests. Mandelin's Test—yellow; Marquis Test—yellow; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 74; system TB—Rf 52; system TC—Rf 79. (Acidified iodoplatinate solution, strong reaction.)

Gas Chromatography. System GA—RI 2686.

Mass Spectrum. Principal peaks at m/z 105, 77, 106, 44, 51, 128, 78, 40.

Dose. 120 to 300 mg daily, usually in combination with broxyquinoline.

Broxyquinoline

Antiprotozoal

Synonym. Broxichinolinum

Proprietary Name. It is an ingredient of Intestopan.

5,7-Dibromoquinolin-8-ol

$\text{C}_9\text{H}_5\text{Br}_2\text{NO} = 303.0$

CAS—521-74-4

A cream-coloured powder. M.p. 196°.

Practically **insoluble** in water; soluble in chloroform.

Colour Tests. Liebermann's Test—orange; Marquis Test—yellow; Millon's Reagent—red; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 51; system TB—Rf 00; system TC—Rf 06. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—263 nm ($A_1^1 = 800$ b); ethanol—249 nm ($A_1^1 = 1525$ b), 325 nm ($A_1^1 = 125$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1316, 1190, 930, 806, 1258, 782 (KBr disk).

Mass Spectrum. Principal peaks at m/z 303, 301, 305, 115, 194, 196, 114, 87.

Quantification. COLORIMETRY. In urine—L. Berggren and O. Hansson, *Clin. Pharmac. Ther.*, 1968, 9, 67–70. In urine—L. A. M. Rodriguez and J. A. Close, *Biochem. Pharmac.*, 1968, 17, 1647–1653.

Disposition in the Body. Absorbed after oral administration. About 36% of a dose is excreted in the urine in 24 hours, mainly as the glucuronide conjugate; very little unchanged drug is excreted and 8-hydroxyquinoline accounts for less than 2% of the dose.

REFERENCE. L. A. M. Rodriguez and J. A. Close, *ibid.*

Dose. 0.6 to 1.5 g daily, usually in combination with broxaline.

Brucine

Alkaloid

Synonym. Dimethoxystyrychne

10,11-Dimethoxystyrychne

$C_{23}H_{26}N_2O_4 \cdot 4H_2O = 466.5$

CAS—357-57-3 (anhydrous)

An alkaloid present in the seeds of *Strychnos nux-vomica* and other species of *Strychnos* (Loganiaceae).

Small white crystals. M.p. of the anhydrous base, 178° and of the hydrated form, 105°.

Soluble 1 in 1320 of water, 1 in 1.3 of ethanol, 1 in 5 of chloroform, and 1 in 187 of ether.

Brucine Sulphate

$(C_{23}H_{26}N_2O_4)_2 \cdot H_2SO_4 \cdot 7H_2O = 1013$

CAS—4845-99-2 (anhydrous); 60583-39-3 (heptahydrate)

Small white crystals or powder.

Soluble 1 in 75 of cold water, 1 in about 10 of boiling water, 1 in 105 of ethanol, and 1 in 170 of chloroform.

Dissociation Constant. pK_a 2.3, 8.0 (25°).

Colour Test. Liebermann's Test—red.

Thin-layer Chromatography. System TA—Rf 16; system TB—Rf 00; system TC—Rf 17. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 3280.

High Pressure Liquid Chromatography. System HA— k' 11.1 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—265 nm ($A_1^1 = 330$ a), 300 nm; aqueous alkali—266 nm ($A_1^1 = 320$ a), 304 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1500, 1660, 1280, 1195, 1120, 1212 (KBr disk).

Mass Spectrum. Principal peaks at m/z 394, 395, 379, 392, 120, 197, 203, 393.

Bucilizine

Antihistamine

1-(4-*tert*-Butylbenzyl)-4-(4-chlorobenzhydryl)piperazine

$C_{28}H_{33}ClN_2 = 433.0$

CAS—82-95-1

Bucilizine Hydrochloride

Proprietary Names. Aphilan R; Bucladin-S; Longifene. It is an ingredient of Equivert and Migravele (pink tablets).

$C_{28}H_{33}ClN_2 \cdot 2HCl = 506.0$

CAS—129-74-8

A white crystalline powder. M.p. 230° to 240°.

Slightly **soluble** in water.

Thin-layer Chromatography. System TA—Rf 75; system TB—Rf 61; system TC—Rf 83. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 3286.

High Pressure Liquid Chromatography. System HA—k' 0.7.

Ultraviolet Spectrum. Methanol—255 nm, 260 nm ($A_1^1 = 19$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1002, 1131, 754, 800, 1075, 694 (KBr disk).

Mass Spectrum. Principal peaks at m/z 231, 147, 285, 232, 201, 132, 165, 166.

Dose. 25 to 150 mg of buclizine hydrochloride daily.

Buclosamide

N-Butyl-4-chlorosalicylamide

$C_{11}H_{14}ClNO_2 = 227.7$

CAS—575-74-6

Antifungal

A white crystalline powder. M.p. about 91°.

Practically **insoluble** in water; soluble 1 in 3 of ethanol, and 1 in 3 of ether.

Colour Tests. Folin-Ciocalteu Reagent—blue; Mandelin's Test—green → blue rim; Millon's Reagent—red.

Thin-layer Chromatography. System TA—Rf 90; system TB—Rf 02; system TC—Rf 67. (Location under ultraviolet light, blue fluorescence; acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—245 nm ($A_1^1 = 532$ b), 297 nm ($A_1^1 = 204$ b); aqueous alkali—247 nm ($A_1^1 = 391$ b), 325 nm ($A_1^1 = 323$ a); ethanol—243 nm ($A_1^1 = 497$ a), 301 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1543, 898, 1190, 1590, 1201, 1506 (KBr disk).

Mass Spectrum. Principal peaks at m/z 155, 157, 227, 154, 185, 44, 30, 156.

Use. Buclosamide has been applied topically in a concentration of 10%.

Bufexamac

Analgesic

Proprietary Names. Droxyaryl; Norfemac; Paraderm; Parfenac.

2-(4-Butoxyphenyl)acetoxyhydroxamic acid

$C_{12}H_{17}NO_3 = 223.3$

CAS—2438-72-4

Almost colourless pearly flakes. M.p. 158° to 160°, with decomposition.

Practically **insoluble** in water.

Thin-layer Chromatography. System TD—Rf 11; system TE—Rf 18; system TF—Rf 19; system TG—Rf 36.

Gas Chromatography. System GD—retention time of methyl derivative 1.12 relative to n -C₁₆H₃₄.

High Pressure Liquid Chromatography. System HD—k' 1.95.

Ultraviolet Spectrum. Aqueous alkali—275 nm ($A_1^1 = 72$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1612, 1234, 1515, 980, 1052, 1176.

Mass Spectrum. Principal peaks at m/z 107, 163, 223, 108, 29, 164, 41, 57.

Dose. 0.75 to 1.5 g daily.

Buformin

Antidiabetic

1-Butylbiguanide

$C_6H_{15}N_5$; 157.2

CAS—692-13-7

Buformin Hydrochloride

Proprietary Names. Silubin; Sindiatil.

$C_6H_{15}N_5 \cdot HCl$; 193.7

CAS—1190-53-0

A fine white crystalline powder. M.p. 174° to 177°.

Soluble in water and ethanol.

Thin-layer Chromatography. *System TA*—Rf 02; *system TB*—Rf 00; *system TC*—Rf 00.

Ultraviolet Spectrum. Aqueous alkali—230 nm ($A_1^1 = 919$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1530, 1634, 1666, 1562, 1587, 1149 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 114, 85, 30, 101, 86, 44, 72.

Quantification. **ULTRAVIOLET SPECTROPHOTOMETRY.** In urine—E. R. Garrett and J. Tsau, *J. pharm. Sci.*, 1972, 61, 1404–1410. In plasma or whole blood—E. R. Garrett *et al.*, *ibid.*, 1411–1418.

GAS CHROMATOGRAPHY. In biological fluids or tissues: AFID—G. de Groot *et al.*, *J. analyt. Toxicol.*, 1980, 4, 281–285. In plasma or urine: sensitivity 1 ng/ml, ECD—S. B. Matin *et al.*, *Analyt. Chem.*, 1975, 47, 545–548.

Disposition in the Body. Absorbed after oral administration. About 35% of an oral dose is excreted in the urine as unchanged drug in 24 hours and up to 30% is eliminated in the faeces; after

intravenous administration about 90% is excreted unchanged in the urine in 12 hours.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.2 to 0.6 µg/ml.

Following a single oral dose of 100 mg to 6 subjects, a mean peak plasma concentration of 0.4 µg/ml was reported after 2.5 hours; plasma concentrations greater than 0.2 µg/ml were maintained up to 8 hours after the dose (H. Gutsche *et al.*, *Arzneimittel-Forsch.*, 1976, 26, 1227–1229).

TOXICITY. Lactic acidosis is associated with plasma concentrations greater than 1 µg/ml.

An 84-year-old diabetic died 6 hours after admission to hospital with severe lactic acidosis caused by buformin. The plasma concentration on admission was 5.5 µg/ml. Postmortem tissue concentrations were: plasma 3.2 µg/ml, bile 6.3 µg/ml, heart 3.0 µg/g, kidney 98 µg/g, liver 5.2 µg/g, lung 2.8 µg/g (G. de Groot *et al.*, *J. analyt. Toxicol.*, 1980, 4, 281–285).

HALF-LIFE. Plasma half-life, about 2 to 6 hours.

VOLUME OF DISTRIBUTION. About 2 litres/kg.

PROTEIN BINDING. In plasma, about 10%.

Dose. 100 to 300 mg of buformin hydrochloride daily.

Bufotenine

Hallucinogen

Synonyms. *NN*-Dimethylserotonin; 5-Hydroxy-*NN*-dimethyltryptamine; Mappine.

3-(2-Dimethylaminoethyl)indol-5-ol

$C_{12}H_{16}N_2O$; 204.3

CAS—487-93-4

An indole alkaloid obtained from the seeds and leaves of *Piptadenia peregrina* and *P. macrocarpa* (Mimosaceae). It has also been isolated from species of *Amanita* (Agaricaceae) and from the skin glands of toads (*Bufo* spp.).

A white crystalline powder. M.p. 138° to 140°.

Practically **insoluble** in water; freely soluble in ethanol; slightly soluble in ether; soluble in dilute acids and alkalis.

Colour Test. Marquis Test—green-brown.

Thin-layer Chromatography. System TA—Rf 35; system TB—Rf 00; system TC—Rf 01. (Van Urk reagent, violet.)

Gas Chromatography. System GA—RI 2030.

High Pressure Liquid Chromatography. System HA— k' 3.1.

Ultraviolet Spectrum. Aqueous acid—278 nm ($A_1^1 = 269$ b), 297 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1232, 824, 1493, 1615, 792, 1052 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 204, 146, 59, 42, 160, 43, 159.

Quantification. GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In urine: detection limit 300 pg/ml—M. Räisänen and J. Kärrkkäinen, *J. Chromat.*, 1979, 162; *Biomed. Appl.*, 4, 579–584.

Bufylline

Xanthine Bronchodilator

Synonyms. Ambuphylline; Theophylline-aminoisobutanol.

Proprietary Names. Butaphyllamine; Butoid. It is an ingredient of Nethaprin and Nethaprin Dospan.

2-Amino-2-methylpropan-1-ol theophyllinate

$C_{11}H_{19}N_5O_3 = 269.3$

CAS—5634-34-4

A white crystalline powder. M.p. about 255°. Slightly soluble in water.

Colour Test. Amalic Acid Test—red/violet.

Gas Chromatography. System GA—RI 2301.

Ultraviolet Spectrum. Aqueous acid—271 nm ($A_1^1 = 350$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1665, 1712, 1636, 1562, 740, 1180 (KBr disk).

Mass Spectrum. Principal peaks at m/z 180, 95, 68, 41, 58, 53, 123, 96.

Dose. 60 to 120 mg every 3 to 4 hours.

Bumetanide

Diuretic

Proprietary Names. Burinex; Fordiuran.

3-Butylamino-4-phenoxy-5-sulphamoylbenzoic acid

$C_{17}H_{20}N_2O_5S = 364.4$

CAS—28395-03-1

A white crystalline powder. M.p. about 230°.

Colour Tests. Koppanyi-Zwicker Test—violet; Liebermann's Test—brown-orange; Mercurous Nitrate—black.

Thin-layer Chromatography. System TD—Rf 01; system TE—Rf 03; system TF—Rf 10.

Ultraviolet Spectrum. Aqueous acid—340 nm ($A_1^1 = 80$ b); aqueous alkali—317 nm ($A_1^1 = 87$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1695, 1215, 1199, 1153, 1587, 1280 (KBr disk).

Mass Spectrum. Principal peaks at m/z 321, 364, 304, 240, 168, 91, 322, 365.

Quantification. GAS CHROMATOGRAPHY. In serum or urine: sensitivity 1 ng/ml, FID—D. L. Davies *et al.*, *Clin. Pharmac. Ther.*, 1974, 15, 141–155.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: detection limit in plasma 5 ng/ml, fluorescence detection—D. E. Smith, *J. pharm. Sci.*, 1982, 71, 520–523.

RADIOIMMUNOASSAY. In plasma or urine: sensitivity 1 ng/ml—W. R. Dixon *et al.*, *J. pharm. Sci.*, 1976, 65, 701–704.

Disposition in the Body. Rapidly and completely absorbed after oral administration. Metabolised to some extent by hydroxylation of the butyl side-chain to give the 2'-, 3'-, and 4'-alcohols; the 3'-carboxylic acid and desbutyl metabolites have also been reported. About 50% of a dose is excreted in the urine as unchanged drug in 24 hours together with 4 to 6% as the 3'-alcohol. A total of about 80% of a dose is excreted in the urine and 10% to 15% is eliminated in the faeces in 48 hours.

THERAPEUTIC CONCENTRATION.

After a single dose of 1 mg given to 12 subjects, a mean peak plasma concentration of 0.03 µg/ml was attained in 1 to 8 hours (A. A. Holazo *et al.*, *J. pharm. Sci.*, 1984, 73, 1108–1113).

HALF-LIFE. Plasma half-life, about 1 hour.

VOLUME OF DISTRIBUTION. About 0.2 litre/kg.

CLEARANCE. Plasma clearance about 3 ml/min/kg.

PROTEIN BINDING. In plasma, about 96%.

NOTE. For a review of bumetanide see A. Ward and R. C. Heel, *Drugs*, 1984, 28, 426–464.

Dose. Usually 1 to 2 mg daily; doses of 20 mg or more daily have been given.

Bunamidine

Anthelmintic (Veterinary)

NN-Dibutyl-4-hexyloxy-1-naphthamide

$C_{25}H_{38}N_2O = 382.6$

CAS—3748-77-4

Bunamidine Hydrochloride

Proprietary Name. Scolaban

$C_{25}H_{38}N_2O \cdot HCl = 419.0$

CAS—1055-55-6

A white crystalline powder. M.p. about 210°.

Soluble 1 in 200 of water, 1 in 2 of ethanol, and 1 in 2 of chloroform; practically insoluble in ether.

Caution. Bunamidine hydrochloride is irritant, especially to the eyes, and should be handled with care.

Bunamidine Hydroxynaphthoate

$C_{36}H_{46}N_2O_4 = 570.8$

CAS—13501-04-7

A pale yellow crystalline powder. M.p. 170° to 175°.

Practically **insoluble** in water; soluble 1 in 35 of ethanol, 1 in 3 of chloroform, and 1 in 300 of ether.

Colour Tests. Mandelin's Test—green; Marquis Test—orange → red.

Thin-layer Chromatography. System TA—Rf 64. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—not eluted.

Ultraviolet Spectrum. Aqueous acid—298 nm ($A_1^1 = 240$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1572, 1079, 1263, 1234, 763, 1511 (KBr disk).

Bunitrolol

Beta-adrenoceptor Blocking Agent

Proprietary Name. Stresson (hydrochloride)

2-(3-*tert*-Butylamino-2-hydroxypropoxy)benzonitrile

$C_{14}H_{20}N_2O_2 = 248.3$

CAS—34915-68-9

A crystalline solid. M.p. about 164°.

Ultraviolet Spectrum. Aqueous acid—232 nm ($A_1^1 = 332$ b), 292 nm ($A_1^1 = 142$ b).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: bunitrolol and 4-hydroxybunitrolol, sensitivity 2.5 ng/ml in plasma and 250 pg/ml in urine, fluorescence detection—A. Nagakura and H. Kohei, *J. Chromat.*, 1982, 232; *Biomed. Appl.*, 21, 137–143.

Disposition in the Body. Absorbed after oral administration and metabolised by *p*-hydroxylation followed by conjugation with glucuronic acid. About 1% of a dose is excreted in the urine as unchanged drug and 5% as the *p*-hydroxy metabolite, in 6 hours.

REFERENCE. A. Nagakura and H. Kohei, *ibid.*

Dose. Bunitrolol hydrochloride has been given in doses of 20 to 40 mg daily.

Buphenine

Vasodilator

Synonym. Nylidrin

1 - (4 - Hydroxyphenyl) - 2 - (1 - methyl - 3 - phenylpropyl-amino)propan-1-ol

$C_{19}H_{25}NO_2 = 299.4$

CAS—447-41-6

M.p. 111° to 112°.

Buphenine Hydrochloride

Proprietary Names. Arlidin; Dilatol; Opino; Penitardon; Pervadil.

$C_{19}H_{25}NO_2 \cdot HCl = 335.9$

CAS—849-55-8

A white crystalline powder. M.p. 223° to 226°.

Soluble 1 in 65 of water and 1 in 40 of ethanol; slightly soluble in chloroform and ether.

Colour Test. Marquis Test—red.

Thin-layer Chromatography. System TA—Rf 74; system TB—Rf 03; system TC—Rf 14. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, brown; acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—RI 2314.

High Pressure Liquid Chromatography. System HA—k' 0.9.

Ultraviolet Spectrum. Aqueous acid—273 nm ($A_1^1 = 40$ a); aqueous alkali—242 nm ($A_1^1 = 390$ b), 291 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1512, 1220, 750, 695, 1182, 837 (KBr disk).

Mass Spectrum. Principal peaks at m/z 91, 133, 176, 174, 44, 107, 92, 177.

Quantification. GAS CHROMATOGRAPHY. In urine: FID—H. Li and P. Cervoni, *J. pharm. Sci.*, 1976, 65, 1352–1356.

Disposition in the Body. Readily absorbed after oral administration. About 5% of a single dose is excreted in the urine as unchanged drug in 24 hours.

Toxicity. The estimated minimum lethal dose in adults is 2 g and in children 200 mg.

Dose. 18 to 48 mg of buphenine hydrochloride daily.

Bupivacaine

Local Anaesthetic

(±)-(1-Butyl-2-piperidyl)formo-2',6'-xylylide
 $C_{18}H_{28}N_2O = 288.4$
 CAS—2180-92-9

M.p. 107° to 108°.

Bupivacaine Hydrochloride

Proprietary Names. Carbostesin; Marcain(e).

$C_{18}H_{28}N_2O \cdot HCl \cdot H_2O = 342.9$

CAS—18010-40-7 (anhydrous); 14252-80-3 (monohydrate)

A white crystalline powder. M.p. about 248° to 250°, with decomposition.

Soluble 1 in 25 of water and 1 in 8 of ethanol; slightly soluble in acetone, chloroform, and ether.

Dissociation Constant. pK_a 8.1.

Thin-layer Chromatography. System TA—Rf 69; system TB—Rf 42; system TC—Rf 73; system TL—Rf 65. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2273.

High Pressure Liquid Chromatography. System HA— k' 0.9; system HQ— k' 7.19; system HR— k' 0.86.

Ultraviolet Spectrum. Aqueous acid—263 nm ($A_1^{1\%} = 16$ a), 271 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1667, 1522, 1279, 1222, 787, 944 (bupivacaine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 140, 141, 84, 41, 29, 96, 56, 55.

Quantification. GAS CHROMATOGRAPHY. In serum: bupivacaine and 2',6'-pipecoloxylidide, sensitivity 50 ng/ml for both compounds, AFID—L. J. Lesko *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 226–231. In blood: sensitivity 15 ng/ml, FID—A. Berlin *et al.*, *J. Pharm. Pharmac.*, 1973, 25, 466–469.

Disposition in the Body. Bupivacaine is metabolised in the liver by oxidative dealkylation to 2',6'-pipecoloxylidide (PPX); 3'- and 4'-hydroxylation also occur. Less than 10% of a dose is excreted in the urine as unchanged drug in 24 hours.

THERAPEUTIC CONCENTRATION.

After slow intravenous infusion of 1.35 mg/kg to 3 subjects, peak venous-plasma concentrations of 2.6 to 4.5 µg/ml were reported 3 to 17 minutes after completion of the infusion (L. E. Mather *et al.*, *Clin Pharmac. Ther.*, 1971, 12, 935–943).

After epidural administration of 150 mg with adrenaline to 12 subjects, mean peak plasma concentrations of 1.1 µg/ml were reported at 0.3 hour and peak cerebrospinal fluid concentrations averaged 30 µg/ml at 0.5 hour (G. R. Wilkinson and P. C. Lund, *Anesthesiology*, 1970, 2, 482–486).

TOXICITY. Bupivacaine is several times more toxic than lignocaine. Muscular rigidity has been reported in 2 subjects having blood concentrations of 9 and 12 µg/ml following the administration of approximately 210 mg, and convulsions have been reported at plasma concentrations greater than 4 µg/ml.

HALF-LIFE. Plasma half-life, about 1 to 3 hours, increased in neonates.

VOLUME OF DISTRIBUTION. About 1 litre/kg.

CLEARANCE. Plasma clearance, about 8 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 1.4.

PROTEIN BINDING. In plasma, about 90%.

NOTE. For a review of the clinical pharmacokinetics of local anaesthetics see G. T. Tucker and L. E. Mather, *Clin. Pharmacokin.*, 1979, 4, 241–278.

Dose. Bupivacaine hydrochloride is given by injection as a 0.25 or 0.5% solution (calculated as the anhydrous hydrochloride); maximum recommended dose is 2 mg/kg in any 4-hour period.

Buprenorphine

Narcotic Analgesic

(6R,7R,14S)-17-Cyclopropylmethyl-7,8-dihydro-7-[(1S)-1-hydroxy-1,2,2-trimethylpropyl]-6-O-methyl-6,14-ethano-17-normorphine

$C_{29}H_{41}NO_4 = 467.6$

CAS—52485-79-7

Crystals. M.p. 209°.

Buprenorphine Hydrochloride

Proprietary Names. Buprex; Temgesic.

$C_{29}H_{41}NO_4 \cdot HCl = 504.1$

CAS—53152-21-9

A white crystalline powder.

Dissociation Constant. pK_a 8.5, 10.0.

Colour Tests. Liebermann's Test—black; Marquis Test—violet.

Thin-layer Chromatography. *System TA*—Rf 76; *system TB*—Rf 09; *system TC*—Rf 68.

High Pressure Liquid Chromatography. *System HA*— k' 0.4; *system HC*— k' 0.05.

Ultraviolet Spectrum. Aqueous acid—286 nm ($A_1^1 = 33$ b); aqueous alkali—300 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1320, 1077, 1503, 1155, 1120, 947 (buprenorphine hydrochloride, KCl disk).

Mass Spectrum. Principal peaks at m/z 55, 378, 43, 29, 57, 410, 379, 84.

Quantification. RADIOIMMUNOASSAY. In plasma: sensitivity 50 pg/ml—A. J. Bartlett *et al.*, *Eur. J. clin. Pharmac.*, 1980, 18, 339–345.

Disposition in the Body. Absorbed after parenteral or sublingual administration and metabolised mainly by *N*-dealkylation and conjugation. It is eliminated mainly in the faeces with a small proportion excreted in the urine, as metabolites.

THERAPEUTIC CONCENTRATION.

Peak plasma concentrations of 0.0005 to 0.0009 μg/ml (mean 0.0007) were reported in 5 subjects about 3 hours after a sublingual dose of 0.4 mg (administered 3 hours after a 0.3 mg intravenous dose) (R. E. S. Bullingham *et al.*, *Br. J. clin. Pharmac.*, 1982, 13, 665–673).

HALF-LIFE. Plasma half-life, 4 to 6 hours.

VOLUME OF DISTRIBUTION. About 2.5 litres/kg.

PROTEIN BINDING. In plasma, about 96%.

Dose. The equivalent of 300 to 600 μg of buprenorphine given parenterally, or 200 to 400 μg by the sublingual route, every 6 to 8 hours.

Busulphan

Antineoplastic

Synonyms. Busulfan; Myelosan.

Proprietary Names. Misulban; Myleran.

Tetramethylene di(methanesulphonate)

$C_6H_{14}O_6S_2 = 246.3$

CAS—55-98-1

A white crystalline powder. M.p. 115° to 118°.

Soluble 1 in 750 of water and 1 in 25 of acetone; slightly soluble in ethanol.

Caution. Busulphan is irritant; avoid contact with skin and mucous membranes.

Ultraviolet Spectrum. Methanol—256 nm ($A_1^1 = 20$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1178, 934, 861, 980, 962, 773 (KBr disk).

Quantification. GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma: sensitivity 10 ng/ml—H. Ehrsson and M. Hassan, *J. pharm. Sci.*, 1983, 72, 1203–1205.

Disposition in the Body. Readily absorbed after oral administration. It is mainly excreted in the urine as metabolites; about 1% of a dose is excreted in the urine unchanged in 24 hours.

**THERAPEUTIC CONCENTRATION.**

Following single oral doses of 6 mg to 5 subjects, peak plasma concentrations of 0.05 to 0.13 µg/ml (mean 0.08) were reported (H. Ehrsson *et al.*, *Clin. Pharmac. Ther.*, 1983, 34, 86-89).

HALF-LIFE. Plasma half-life, about 2 to 3 hours.

Dose. Usually 2 to 4 mg daily; maintenance, 0.5 to 2 mg daily.

Butacaine*Local Anaesthetic*

3-Dibutylaminopropyl 4-aminobenzoate

$C_{18}H_{30}N_2O_2 = 306.4$

CAS—149-16-6

A liquid.

Butacaine Sulphate

Proprietary Name. It is an ingredient of Rhinamid.

$(C_{18}H_{30}N_2O_2)_2 \cdot H_2SO_4 = 711.0$

CAS—149-15-5

A white, very hygroscopic, crystalline powder. Unstable to light and moisture. M.p. about 100°.

Soluble 1 in 1.5 of water, 1 in 2 of ethanol, 1 in 2.5 of chloroform, and 1 in 2000 of ether; slightly soluble in acetone.

Dissociation Constant. pK_a 9.0.

Colour Test. Diazotisation—red.

Thin-layer Chromatography. *System TA*—Rf 71; *system TB*—Rf 09; *system TC*—Rf 30; *system TL*—Rf 64. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *ninhydrin spray*, positive; *Van Urk reagent*, bright yellow.)

Gas Chromatography. *System GA*—RI 2457.

High Pressure Liquid Chromatography. *System HA*— k' 1.2; *system HQ*— k' 8.97.

Ultraviolet Spectrum. Aqueous acid—272 nm, 278 nm ($A_1^1 = 72$ b); aqueous alkali—282 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1275, 1165, 1598, 1694, 1639, 1111 (KBr disk).

Mass Spectrum. Principal peaks at m/z 120, 263, 142, 178, 100, 264, 41, 29.

Use. A 2% solution of butacaine sulphate has been used for surface anaesthesia.

Butalamine*Vasodilator*

NN - Dibutyl - *N'* - (3 - phenyl - 1,2,4 - oxadiazol - 5 - yl)-ethylenediamine

$C_{18}H_{28}N_4O = 316.4$

CAS—22131-35-7

**Butalamine Hydrochloride**

Proprietary Names. Adrevil; Surheme.

$C_{18}H_{28}N_4O \cdot HCl = 352.9$

CAS—56974-46-0

A white crystalline powder. M.p. 135° to 141°.

Soluble 1 in 7 of water, 1 in 10 of ethanol, and 1 in 2.5 of chloroform.

Thin-layer Chromatography. *System TA*—Rf 68; *system TD*—Rf 11; *system TE*—Rf 86; *system TF*—Rf 29. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2490.

Ultraviolet Spectrum. Aqueous acid—228 nm ($A_1^1 = 812$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1639, 751, 1603, 694, 1492, 1170.

Mass Spectrum. Principal peaks at m/z 142, 143, 100, 155, 44, 112, 57, 29.

Dose. Butalamine hydrochloride has been given in doses of 160 to 320 mg daily.

Butalbital*Barbiturate*

Synonyms. Alisobumalum; Allylbarbituric Acid; Itobarbital; Tetrallobarbital.

Proprietary Names. Sandoptal. It is an ingredient of Fiorinal.

Note. The name Butalbital has also been applied to talbutal, the *sec*-butyl analogue.

5-Allyl-5-isobutylbarbituric acid

$C_{11}H_{16}N_2O_3 = 224.3$

CAS—77-26-9

A white crystalline powder. M.p. 138° to 141°.

Slightly **soluble** in cold water; soluble in boiling water; freely soluble in ethanol, chloroform, and ether; soluble in aqueous solutions of alkali hydroxides and carbonates.

Dissociation Constant. pK_a 7.6 (20°).

Colour Tests. Koppanyi-Zwikker Test—violet; Vanillin Reagent—orange/colourless.

Thin-layer Chromatography. System TD—Rf 54; system TE—Rf 38; system TF—Rf 67; system TH—Rf 67. (Mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown.)

Gas Chromatography. System GA—RI 1668; system GF—RI 2395.

High Pressure Liquid Chromatography. System HG— k' 6.17; system HH— k' 3.48.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—240 nm ($A_1^1 = 439$ a); M sodium hydroxide (pH 13)—255 nm ($A_1^1 = 329$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1690, 1720, 1740, 1310, 1290, 1200 (KBr disk).

Mass Spectrum. Principal peaks at m/z 41, 167, 168, 39, 124, 97, 141, 181.

Wavelength

Quantification. See under Amylobarbitone.

Disposition in the Body. Absorbed after oral administration. About 5% of a dose is excreted in the urine as unchanged drug in 96 hours and 20 to 60% as 5-(2,3-dihydroxypropyl)-5-isobutylbarbituric acid.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 1 to 10 µg/ml.

TOXICITY. Plasma concentrations of 10 to 25 µg/ml are usually associated with toxic effects.

The following concentrations were reported in one fatality attributed to butalbital overdose: blood 26 µg/ml, liver 50 µg/g (R. C. Baselt and R. H. Cravey, *J. analyt. Toxicol.*, 1977, 1, 81-103).

HALF-LIFE. Derived from urinary excretion data, about 30 to 40 hours.

Dose. 200 mg as a hypnotic; 150 to 400 mg daily as a sedative.

Butanilicaine*Local Anaesthetic*

2-Butylamino-6'-chloroaceto-*o*-toluidide

$C_{13}H_{19}ClN_2O = 254.8$

CAS—3785-21-5

Crystals. M.p. 45° to 46°.

Butanilicaine Phosphate

Proprietary Name. Hostacain (also as hydrochloride).

$C_{13}H_{19}ClN_2O \cdot H_3PO_4 = 352.8$

CAS—2081-65-4

Crystals. M.p. 126° to 127°.

Colour Tests. Aromaticity (Method 2)—colourless/orange; Koppanyi-Zwikker Test—violet; Liebermann's Test—orange.

Thin-layer Chromatography. System TA—Rf 76; system TB—Rf 14; system TC—Rf 54; system TL—Rf 61. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2025.

High Pressure Liquid Chromatography. System HQ—k' 4.42.

Ultraviolet Spectrum. Aqueous acid—267 nm ($A_1^1 = 15$ b), 275 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1495, 1694, 770, 1136, 1562, 1587.

Mass Spectrum. Principal peaks at m/z 86, 30, 72, 44, 141, 42, 29, 57.

Quantification. GAS CHROMATOGRAPHY. In horse plasma or urine: sensitivity 5 ng/ml, AFID—F. T. Delbeke and M. Debackere, *J. Chromat.*, 1982, 237, 344–349.

Dose. Butanilcaine phosphate has been administered by injection, as a 0.5 to 3% solution.

Butaperazine

Tranquilliser

Synonym. Butyrylperazine

1-{10-[3-(4-Methylpiperazin-1-yl)propyl]phenothiazin-2-yl}-butan-1-one

$C_{24}H_{31}N_3OS = 409.6$

CAS—653-03-2

A yellow oil. B.p. 195° to 210°.

Butaperazine Maleate

Synonym. Butaperazine Dimaleate

Proprietary Name. Repoise

$C_{24}H_{31}N_3OS \cdot 2C_4H_4O_4 = 641.7$

CAS—1063-55-4

A yellow crystalline powder. M.p. about 195°.

Soluble in water; practically insoluble in chloroform and ether.

Butaperazine Phosphate

Synonym. Butaperazine Diphosphate

$C_{24}H_{31}N_3OS \cdot 2H_3PO_4 = 605.6$

CAS—7389-45-9

A yellow crystalline powder. M.p. 161° to 162°.

Soluble in water; practically insoluble in chloroform and ether.

Colour Tests. Mandelin's Test—brown-violet; Marquis Test—brown-violet.

Thin-layer Chromatography. System TA—Rf 53; system TB—Rf 24; system TC—Rf 37. (Acidified potassium permanganate solution, positive.)

High Pressure Liquid Chromatography. System HA—k' 3.4.

Ultraviolet Spectrum. Aqueous acid—242 nm ($A_1^1 = 609$ a), 277 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1675, 749, 1279, 1193, 1163, 1143.

Mass Spectrum. Principal peaks at m/z 113, 70, 409, 43, 141, 283, 42, 127.

Quantification. SPECTROFLUORIMETRY. In plasma—D. H. Manier *et al.*, *Clinica chim. Acta*, 1974, 57, 225–230.

GAS CHROMATOGRAPHY. In biological fluids: sensitivity 5 ng/ml, AFID—J. I. Javaid *et al.*, *J. chromatogr. Sci.*, 1979, 17, 666–670.

Disposition in the Body. Readily absorbed after oral administration. Metabolised to the sulphoxide and sulphone; other unidentified metabolites have been detected in plasma.

THERAPEUTIC CONCENTRATION.

Following oral administration of 40 mg as a single dose to 13 subjects, peak plasma concentrations of 0.07 to 0.69 $\mu\text{g/ml}$ (mean 0.28) were attained in 2 to 4 hours; peak erythrocyte concentrations of 0.01 to 0.52 $\mu\text{g/ml}$ (mean 0.11) were also reported (D. L. Garver *et al.*, *Archs gen. Psychiat.*, 1976, 33, 862–866).

Following oral administration of 20 mg twice a day to 9 subjects, minimum steady-state plasma concentrations of 0.02 to 0.20 $\mu\text{g/ml}$ (mean 0.09), and erythrocyte concentrations of 0.01 to 0.06 $\mu\text{g/ml}$ (mean 0.03) were reported; therapeutic effect appeared to correlate with erythrocyte concentrations in the range 0.03 to 0.06 $\mu\text{g/ml}$ (R. Casper *et al.*, *Archs gen. Psychiat.*, 1980, 37, 301–305).

HALF-LIFE. Plasma half-life, 5 to 30 hours (mean 12).

Dose. Usually the equivalent of 15 to 30 mg of butaperazine daily; maximum of 100 mg daily.

Butethamate

Antispasmodic/Bronchodilator

Synonym. Butetamate

2-Diethylaminoethyl 2-phenylbutyrate

$C_{16}H_{25}NO_2 = 263.4$

CAS—14007-64-8

Butethamate Citrate

Proprietary Name. It is an ingredient of CAM.

$C_{16}H_{25}NO_2 \cdot C_6H_8O_7 = 455.5$

CAS—13900-12-4

Colourless crystals. M.p. 107° to 110°.

Soluble 1 in 10 of water and 1 in 40 of ethanol.

Thin-layer Chromatography. System TA—Rf 69; system TB—Rf 59; system TC—Rf 57. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1754.

High Pressure Liquid Chromatography. System HA— k' 1.7.

Ultraviolet Spectrum. Aqueous acid—253 nm, 258 nm ($A_1^1 = 7.6$ b), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1730, 1158, 1194, 694, 1265, 1219 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 99, 91, 191, 87, 119, 58, 248.

Dose. Butethamate citrate has been given in doses of 18 to 90 mg daily.

Butobarbitone

Barbiturate

Synonyms. Butethal; Butobarbital (distinguish from Butabarbitone).

Proprietary Names. Sonabarb; Soneryl.

5-Butyl-5-ethylbarbituric acid

$C_{10}H_{16}N_2O_3 = 212.2$

CAS—77-28-1

Colourless crystals or white crystalline powder. M.p. 122° to 127°.

Soluble 1 in 250 of water, 1 in 1 of ethanol, 1 in 3 of chloroform, and 1 in 10 of ether; soluble in aqueous solutions of alkali hydroxides and carbonates.

Dissociation Constant. pK_a 8.0 (25°).

Partition Coefficient. Log P (octanol/pH 7.4), 1.7.

Colour Tests. Koppanyi-Zwicker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. System TD—Rf 50; system TE—Rf 38; system TF—Rf 65; system TH—Rf 68. (Mercuric chloride-diphenylcarbazone reagent, positive; mercurous nitrate spray, black; Zwicker's reagent, pink.)

Gas Chromatography. System GA—RI 1665; system GF—RI 2390.

High Pressure Liquid Chromatography. System HG— k' 5.43; system HH— k' 3.42.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—239 nm ($A_1^1 = 477$ a); M sodium hydroxide (pH 13)—254 nm ($A_1^1 = 388$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1696, 1727, 1760, 1242, 850, 1215 (KBr disk).

Mass Spectrum. Principal peaks at m/z 141, 156, 41, 55, 98, 39, 142, 155; 3'-hydroxybutobarbitone 156, 141, 45, 157, 41, 29, 55, 27.

Quantification. See also under Amylobarbitone.

Butorphanol Tartrate

Proprietary Name. Stadol

$C_{21}H_{29}NO_2 \cdot C_4H_6O_6 = 477.6$

CAS—58786-99-5

A white crystalline powder. M.p. 217° to 219°, with decomposition. Sparingly **soluble** in water; slightly soluble in methanol; practically insoluble in ethanol, chloroform, and ether; soluble in dilute acids.

Colour Tests. Liebermann's Test—black; Marquis Test—grey.

Ultraviolet Spectrum. Aqueous acid—278 nm ($A_1^{1\%} = 62$ b); aqueous alkali—299 nm.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In urine: butorphanol and metabolites—J. N. T. Gilbert and J. W. Powell, *Eur. J. drug Met. Pharmacokinet.*, 1976, 1, 188–193.

Disposition in the Body. Readily absorbed after oral administration. Metabolic reactions include side-chain oxidation to form the 3'-hydroxy, 3'-oxo, and 3'-carboxypropyl metabolites. About 5 to 9% of an oral dose is excreted in the urine unchanged, 22 to 28% as 3'-hydroxybutorphanol, 14 to 18% as 3'-oxobutorphanol, and 4 to 8% as 5-(3'-carboxypropyl)-5-ethylbarbituric acid.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 2 to 15 µg/ml.

A single oral dose of 200 mg given to 5 subjects, produced peak plasma concentrations of 2.9 to 4.1 µg/ml (mean 3.6) in 0.6 to 2 hours; following oral doses of 200 mg daily for 3 days to 2 subjects, plasma concentrations of 6.5 and 6.4 µg/ml were observed 9 hours after the last dose (D. D. Breimer, *Eur. J. clin. Pharmac.*, 1976, 10, 263–271).

TOXICITY. The estimated minimum lethal dose is 2 g. Toxic effects are associated with plasma concentrations of 14 to 32 to 98 µg/ml and fatalities with blood concentrations of 11 to 30 to 75 µg/ml.

In 3 fatalities attributed to butorphanol overdose, the following postmortem tissue concentrations, µg/ml or µg/g, were reported:

	Butorphanol	3'-Hydroxybutorphanol
Blood	18, 22, 49	—, 3, —
Bile	49, 27, 131	204, 4, 312
Kidney	31, 23, 72	—, 8, 12
Liver	47, 58, 83	2, 10, 17
Lung	26, 19, 52	—, 8, 19
Urine	4, 26, 38	259, —, 5

(A. E. Robinson and R. D. McDowall, *J. Pharm. Pharmac.*, 1979, 31, 357–365).

HALF-LIFE. Plasma half-life, about 40 hours following single doses, but may be reduced to about 30 hours after multiple dosing.

VOLUME OF DISTRIBUTION. About 0.8 litre/kg.

PROTEIN BINDING. In plasma, about 26%.

Dose. 100 to 200 mg, as a hypnotic.

Butorphanol

Narcotic Analgesic

Synonym. Levo-BC-2627

(–)-9a-Cyclobutylmethylmorphinan-3,14-diol

$C_{21}H_{29}NO_2 = 327.5$

CAS—42408-82-2

Infra-red Spectrum. Principal peaks at wavenumbers 1269, 1130, 1233, 1575, 1249, 1303 (butorphanol tartrate, KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 272, 273, 41, 327, 145, 76, 42, 29.

Quantification. GAS CHROMATOGRAPHY. In serum: sensitivity 2 ng/ml, ECD—M. Pfeffer *et al.*, *J. pharm. Sci.*, 1980, 69, 801–803.

RADIOIMMUNOASSAY. In serum: sensitivity <25 pg—K. A. Pittman *et al.*, *J. pharm. Sci.*, 1980, 69, 160–163.

Disposition in the Body. Well absorbed after oral or intramuscular administration; bioavailability about 17%. It undergoes extensive first-pass metabolism, mainly by hydroxylation, dealkylation and conjugation. The major metabolite is 3'-hydroxybutorphanol. About 70% of a dose is excreted in the urine and 13% eliminated in the faeces in 5 days. In 24 hours, 5 to 10% of a dose is excreted in the urine as unchanged drug, 5 to 10% as free and conjugated norbutorphanol, and about 50% as 3'-hydroxybutorphanol.

**THERAPEUTIC CONCENTRATION.**

A single intramuscular dose of 2 mg, administered to 6 subjects, produced a mean peak plasma concentration of 0.002 μg/ml of butorphanol in 0.5 to 1 hour, and a mean peak plasma concentration of 0.001 μg/ml of 3'-hydroxybutorphanol in 4 to 6 hours (R. C. Gaver *et al.*, *Drug Met. Disp.*, 1980, 8, 230-235).

Following oral administration of 16 mg of butorphanol tartrate to 4 subjects, peak serum concentrations of 0.0003 to 0.003 μg/ml (mean 0.001) were attained in 2 to 4 hours (K. A. Pittman *et al.*, *J. pharm. Sci.*, 1980, 69, 160-163).

HALF-LIFE. Plasma half-life, 2 to 4 hours.

VOLUME OF DISTRIBUTION. About 5 litres/kg.

PROTEIN BINDING. In plasma, about 80%.

NOTE. For a review of butorphanol see R. C. Heel *et al.*, *Drugs*, 1978, 16, 473-505.

Dose. 1 to 4 mg of butorphanol tartrate every 4 hours by intramuscular injection; doses of 4 to 16 mg have been given by mouth.

Butoxyethyl Nicotinate*Topical Vasodilator*

Proprietary Names. It is an ingredient of Actinac and Finalgon.

2-Butoxyethyl nicotinate

$C_{12}H_{17}NO_3 = 223.3$

CAS—13912-80-6

Soluble in ether; slightly soluble in dilute acetic acid.

Thin-layer Chromatography. System TA—Rf 63; system TB—Rf 45; system TC—Rf 69. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1640.

Ultraviolet Spectrum. Methanol—279 nm ($A_1^1 = 152$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1282, 1724, 1111, 740, 1020, 1587.

Use. Topically in a concentration of 2.5%.

Butriptyline*Antidepressant*

(±)-3-(10,11-Dihydro-5H-dibenzo[a,d]cyclohepten-5-yl)-2,N,N-trimethylpropylamine

$C_{21}H_{27}N = 293.5$

CAS—35941-65-2

An oil.

Butriptyline Hydrochloride

Proprietary Name. Evadyne

$C_{21}H_{27}N \cdot HCl = 329.9$

CAS—5585-73-9

A white crystalline powder. M.p. about 186°.

Soluble in water, ethanol, and chloroform; practically insoluble in ether.

Colour Test. Marquis Test—violet.

Thin-layer Chromatography. System TA—Rf 59; system TB—Rf 61; system TC—Rf 48. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2181; system GF—RI 2465.

High Pressure Liquid Chromatography. System HA—butriptyline k' 2.7, norbutriptyline k' 1.7; system HF—k' 7.33.

Ultraviolet Spectrum. Aqueous acid—265 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 757, 1033, 1265, 740, 1098, 1149 (KCl disk).

Mass Spectrum. Principal peaks at m/z 58, 293, 45, 59, 193, 100, 178, 294.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, FID—T. R. Norman *et al.*, *J. Chromat.*, 1977, 134, 524–528.

Disposition in the Body. Readily absorbed after oral administration. It is rapidly metabolised, and the metabolites are thought to undergo enterohepatic circulation; the major metabolite is norbutriptyline. Butriptyline is slowly excreted in the urine mainly as metabolites; up to 25% of a dose is excreted in the urine in 24 hours with less than 2% of the dose as unchanged drug, and about 4% as glucuronide conjugates; about 1 to 2% of a dose is eliminated in the faeces in 24 hours.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 75 mg to 14 subjects, peak plasma concentrations of 0.024 to 0.11 µg/ml (mean 0.05) were attained in about 3 hours (J. Bourgouin *et al.*, *Biopharm. Drug Disp.*, 1981, 2, 123–130).

Following oral administration of 50 mg three times a day to 9 subjects, steady-state plasma-butriptyline concentrations of 0.06 to 0.28 µg/ml (mean 0.15) were reported 6 hours after the final dose; plasma concentrations of norbutriptyline were of a similar order (G. D. Burrows *et al.*, *Med. J. Aust.*, 1977, 2, 604–606).

HALF-LIFE. Plasma half-life, about 20 hours.

PROTEIN BINDING. In plasma, more than 90%.

Dose. The equivalent of 75 to 150 mg of butriptyline daily.

Butyl Aminobenzoate

Local Anaesthetic

Synonyms. Butamben; Butoforme; Scuriforme.

Butyl 4-aminobenzoate

$C_{11}H_{15}NO_2 = 193.2$

CAS—94-25-7

A white crystalline powder. It slowly hydrolyses when boiled with water. M.p. 57° to 59°.

Very slightly **soluble** in water; soluble 1 in 3 of ethanol, and 1 in 2 of ether; soluble in chloroform and in dilute mineral acids.

Butyl Aminobenzoate Picrate

Proprietary Name. Butesin Picrate

$(C_{11}H_{15}NO_2)_2 \cdot C_6H_3N_3O_7 = 615.6$

CAS—577-48-0

A yellow powder. M.p. 109° to 110°.

Very slightly **soluble** in water; soluble in ethanol, chloroform, and ether.

Colour Test. Diazotisation—red.

Gas Chromatography. System GA—RI 1742.

Ultraviolet Spectrum. Aqueous acid—279 nm; aqueous alkali—285 nm; ethanol—294 nm ($A_1^1 = 1065$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1273, 1595, 1681, 1630, 1111, 1163.

Mass Spectrum. Principal peaks at m/z 120, 137, 193, 92, 65, 121, 138, 41.

Dose. The maximum safe dose for topical use is estimated to be 5 g.

Butylated Hydroxyanisole

Antioxidant

Synonym. BHA

Proprietary Names. Embanox BHA; Nipantiox 1-F; Tenox BHA.

2-*tert*-Butyl-4-methoxyphenol

$C_{11}H_{16}O_2 = 180.2$

CAS—25013-16-5

A white crystalline powder or a yellowish-white waxy solid. M.p. 62° to 65°.

It contains a variable proportion of 3-*tert*-butyl-4-methoxyphenol.

Practically **insoluble** in water; soluble 1 in 4 of ethanol, 1 in 2 of chloroform, 1 in 1.2 of ether, and 1 in 2 of propylene glycol; soluble in solutions of alkali hydroxides.

Colour Tests. Dissolve 0.1 g in 10 ml of ethanol, add 2 ml of a 2% solution of borax and a few crystals of 2,6-dichloroquinone-chloroimide—blue (compare blue colour produced by butylated hydroxytoluene).

Dissolve a few crystals in 10 ml of ethanol and add 0.5 ml of a 0.2% solution of ferric ammonium sulphate in 0.5M sulphuric acid—green-blue.

Gas Chromatography. System GA—RI 1462.

Ultraviolet Spectrum. Acid ethanol—228 nm ($A_1^1 = 340$ a), 292 nm ($A_1^1 = 205$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1202, 1220, 1050, 805, 1185, 1294 (KBr disk).

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: detection limit < 100 ng/ml, FID—R. El-Rashidy and S. Niazi, *J. pharm. Sci.*, 1979, 68, 103–104.

Disposition in the Body. Absorbed after oral administration and may be stored in body fat after large doses. Metabolised by *O*-demethylation and conjugation with glucuronic acid and sulphate. Less than 1% of a dose is excreted in the urine unchanged in 24 hours together with 44% as the glucuronide, 26% as the sulphate and about 22% each as the glucuronide and sulphate conjugates of the desmethyl metabolite.

PROTEIN BINDING. In plasma, highly bound.

REFERENCE. R. El-Rashidy and S. Niazi, *Biopharm. Drug Disp.*, 1983, 4, 389–396.

Butylated Hydroxytoluene

Antioxidant

Synonyms. BHT; DBPC.

Proprietary Names. Anullex BHT; Embanox BHT.

2,6-Di-*tert*-butyl-*p*-cresol

$C_{15}H_{24}O = 220.4$

CAS—128-37-0

Colourless crystals or white crystalline powder.

Practically **insoluble** in water; soluble 1 in 4 of ethanol, 1 in 1.1 of chloroform, and 1 in 0.5 of ether; practically insoluble in propylene glycol and in solutions of alkali hydroxides.

Colour Test. Dissolve 0.1 g in 10 ml of ethanol, add 2 ml of a 2% solution of borax and a few crystals of 2,6-dichloroquinonechloroimide—faint blue (compare blue colour produced by butylated hydroxyanisole).

Gas Chromatography. System GA—RI 1490.

Ultraviolet Spectrum. Dehydrated alcohol—278 nm ($A_1^1 = 85$ a).

Disposition in the Body. Readily absorbed after oral administration. About 50% of a dose is excreted in the urine in 24 hours mainly as glucuronide conjugates of oxidation products.

Butylchloral Hydrate

Hypnotic

Synonyms. Croton-Chloral Hydrate; Trichlorobutylidene Glycol.

2,2,3-Trichlorobutane-1,1-diol

$C_4H_7Cl_3O_2 = 193.5$

CAS—76-40-4

Pearly-white crystalline scales. M.p. about 78°.

Soluble 1 in 40 of water, 1 in 0.6 of ethanol (forming an ethanolate), 1 in 20 of chloroform, and 1 in 2 of ether.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 830, 1090, 1051, 1020, 690, 1300 (KBr disk).

Dose. Butylchloral hydrate has been given in a dose of 0.3 to 1.2 g.

Cadaverine

Putrefactive Base

Synonym. Pentamethylenediamine

Pentane-1,5-diamine

$NH_2 \cdot [CH_2]_5 \cdot NH_2 = 102.2$

CAS—462-94-2

A colourless syrupy basic liquid, which fumes and absorbs carbon dioxide on exposure to air. F.p. 9°. B.p. 178° to 180°.

Miscible with water and ethanol; slightly miscible with ether.

Thin-layer Chromatography. System TA—Rf 02. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1035.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1565, 1508, 1600, 1120, 1173, 923 (KBr disk).

Mass Spectrum. Principal peaks at m/z 56, 55, 41, 43, 45, 85, 42, 84.

Disposition in the Body. Cadaverine is formed during putrefaction by bacterial decarboxylation of lysine in the gastro-intestinal tract. It may be deaminated to yield ammonia and an aldehyde, and it may undergo cyclisation to piperidine. The piperidine normally excreted in the urine is from cadaverine.

Caffeine

Xanthine Stimulant

Synonyms. Anhydrous Caffeine; Coffeinum; Guanine; Methyltheobromine; Théine.

Proprietary Names. No Doz; Pro-Plus.

Caffeine is an ingredient of many proprietary preparations—see *Martindale, The Extra Pharmacopoeia*, 28th Edn.

7-Methyltheophylline

$C_8H_{10}N_4O_2 = 194.2$

CAS—58-08-2

An alkaloid obtained from tea waste, or coffee, or from the dried leaves of *Camellia sinensis* (Theaceae), or prepared synthetically; it is also present in guarana, maté, and kola.

Silky white crystals, usually matted together, or a white crystalline powder. It sublimates at about 180°. M.p. 234° to 239°. When crystallised from water, caffeine contains 1 molecule of water of crystallisation, but it is anhydrous when crystallised from ethanol, chloroform, or ether. It is decomposed by strong solutions of caustic alkalis.

Soluble 1 in 60 of water, 1 in 1 of boiling water, 1 in 130 of ethanol, and 1 in 7 of chloroform; slightly soluble in ether; soluble in dilute acids.

Caffeine Citrate

Synonym. Citrated Caffeine

Proprietary Names. It is an ingredient of Antoin, Cojene, and Myolgin.

$C_8H_{10}N_4O_2 \cdot C_6H_8O_7 = 386.3$

CAS—69-22-7

A mixture of caffeine and citric acid containing 47 to 50% of anhydrous caffeine.

A white powder which is decomposed by water.

Soluble 1 in 4 of hot water, dissociating on further dilution with the separation of caffeine on cooling which redissolves in about 32 of water; soluble 1 in 25 of ethanol.

Caffeine Hydrate

Synonym. Caffeine Monohydrate

Proprietary Names. It is an ingredient of Migril and Pardale.

$C_8H_{10}N_4O_2 \cdot H_2O = 212.2$

CAS—5743-12-4

Silky white crystals, usually matted together, or a white crystalline powder. It effloresces in dry air and loses its water of crystallisation when heated, becoming anhydrous at 100°. It sublimates at about 180°. M.p. 234° to 239°.

Soluble 1 in 60 of water and 1 in 110 of ethanol; soluble in chloroform with the separation of water; slightly soluble in ether.

Dissociation Constant. pK_a 14.0 (25°).

Partition Coefficient. Log *P* (octanol/pH 7.4), 0.0.

Colour Test. Amalic Acid Test—orange/violet.

Thin-layer Chromatography. *System TA*—Rf 52; *system TB*—Rf 03; *system TC*—Rf 58. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1810; *system GB*—RI 1862; *system GC*—RI 2376; *system GF*—RI 2340.

High Pressure Liquid Chromatography. *System HA*—*k'* 0.2; *system HC*—*k'* 0.26; *system HS*—*k'* 0.21.

Ultraviolet Spectrum. Aqueous acid—273 nm ($A_1^1 = 504$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1658, 1698, 747, 1548, 1242, 760 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 194, 109, 55, 67, 82, 195, 42, 110.

Quantification. GAS CHROMATOGRAPHY. In plasma: detection limit 50 ng/ml, AFID—I. D. Bradbrook *et al.*, *J. Chromat.*, 1979, 163; *Biomed. Appl.*, 5, 118–122.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma, serum or saliva: detection limit 100 ng/ml, UV detection—D. B. Haughey *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 387–395. In plasma: sensitivity 100 ng/ml, UV detection—S. E. O'Connell and F. J. Zurzola, *J. pharm. Sci.*, 1984, 73, 1009–1011.

Disposition in the Body. Rapidly absorbed after oral administration; bioavailability almost 100%. Metabolic reactions include *N*-demethylation and oxidation to uric acid derivatives. About 85% of a dose is excreted in the urine in 48 hours with up to 40% of the dose as 1-methyluric acid, 10 to 15% as 1-methylxanthine and up to 35% as 5-acetylamino-6-formylamino-3-methyluracil and 5-acetylamino-6-amino-3-methyluracil; other metabolites excreted in the urine include theophylline, 1,7-dimethylxanthine (paraxanthine), 7-methylxanthine, and 1,3-dimethyluric acid. Less than 10% is excreted in the urine as unchanged drug. The extent of *N*-acetylation is genetically determined. Caffeine, theophylline, theobromine, and paraxanthine are found in plasma from dietary sources especially coffee, tea and cocoa. An average cup of coffee or tea contains approximately 100 mg of caffeine.

THERAPEUTIC CONCENTRATION.

Following a single dose of 130 mg to 36 subjects, peak plasma concentrations of 2.5 to 6.8 µg/ml (mean 4.0) were attained in 20 to 40 minutes (S. E. O'Connell and F. J. Zurzola, *J. pharm. Sci.*, 1984, 73, 1009–1011).

Following a single oral dose of 5 mg/kg to 10 subjects, peak plasma concentrations of 6.9 to 16.1 µg/ml (mean 10) were attained in about 0.5 hour (J. Blanchard and S. J. A. Sawers, *Eur. J. clin. Pharmacol.*, 1983, 24, 93–98).

TOXICITY. Fatalities have occurred after the ingestion of 5 to 50 g of caffeine, but recovery following the ingestion of 30 g has

been reported. Toxic effects are associated with blood concentrations greater than 15 µg/ml and fatalities with blood concentrations greater than 80 µg/ml.

The following postmortem tissue concentrations were reported in a fatality due to the ingestion of 5.3 g of caffeine by a 5-year-old child: blood 159 µg/ml, kidney 230 µg/g, liver 198 µg/g, urine 114 µg/ml (V. J. M. DiMaio and J. G. Garriott, *Forens. Sci.*, 1974, 3, 275–278).

In a fatality due to the ingestion of 50 g of caffeine, the following postmortem tissue concentrations were reported: blood 79 µg/ml, brain 105 µg/g, kidney 145 µg/g, liver 214 µg/g, urine 280 µg/ml (E. Grusz-Harday, *Bull. int. Ass. forens. Toxicol.*, 1973, 9(1–2), 6–7).

HALF-LIFE. Plasma half-life, 2 to 10 hours (mean 4).

VOLUME OF DISTRIBUTION. About 0.5 litre/kg.

CLEARANCE. Plasma clearance, 1 to 2 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, 0.93.

SALIVA. Plasma: saliva ratio, about 1.3.

PROTEIN BINDING. In plasma, about 35%.

Dose. 100 to 300 mg.

Camazepam

Tranquilliser

Proprietary Names. Albego; Limpidon.

7-Chloro-2,3-dihydro-1-methyl-2-oxo-5-phenyl-1H-1,4-benzodiazepin-3-yl dimethylcarbamate

$C_{19}H_{18}ClN_3O_3 = 371.8$

CAS—36104-80-0

A white crystalline powder. M.p. 173° to 174°.

Soluble in water and ethanol.

Gas Chromatography. *System GA*—RI 2954.

Ultraviolet Spectrum. Methanol—231 nm ($A_1^1 = 937$ b), 315 nm ($A_1^1 = 67$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1680, 1718, 1193, 1318, 1110, 703.

Mass Spectrum. Principal peaks at m/z 58, 72, 43, 78, 271, 57, 44, 77.

Quantification. GAS CHROMATOGRAPHY. In plasma: limit of detection 1 ng/ml, ECD—G. Cuisinaud *et al.*, *J. Chromat.*, 1979, 178, 314–319.

Dose. 20 to 60 mg daily.

Cambendazole

Anthelmintic

Proprietary Names. Bovicam (vet.). It is an ingredient of Porcam (vet.).

Isopropyl 2-(thiazol-4-yl)-1H-benzimidazol-5-ylcarbamate

$C_{14}H_{14}N_4O_2S = 302.4$

CAS—26097-80-3

A white crystalline powder. M.p. 238° to 240°, with decomposition.

Practically insoluble in water; soluble in ethanol and dimethylformamide; sparingly soluble in acetone.

Ultraviolet Spectrum. Aqueous acid—235 nm ($A_1^1 = 620$ b), 319 nm ($A_1^1 = 689$ b); aqueous alkali—237 nm ($A_1^1 = 936$ b), 314 nm ($A_1^1 = 649$ b).

Mass Spectrum. Principal peaks at m/z 260, 302, 216, 215, 243, 189, 242, 188.

Camphor

Rubefacient

Synonyms. Alcanfor; 2-Camphanone; Camphre Droit (natural); Camphre du Japon (natural); Cānfora.

Proprietary Name. It is an ingredient of Pernomol.

Bornan-2-one

$C_{10}H_{16}O = 152.2$

CAS—76-22-2; 464-49-3 (+)

Camphor is obtained by distillation from the wood of *Cinnamomum camphora* (Lauraceae) and purified by sublimation, or it may be prepared synthetically. Natural camphor is dextrorotatory; the synthetic product is optically inactive.

Colourless transparent or white crystals, crystalline masses, blocks, or powdery masses known as 'flowers of camphor'. M.p. 174° to 181°.

Soluble 1 in 700 to 1 in 800 of water, 1 in 1 of ethanol, 1 in 0.25 of chloroform, and 1 in 1 of ether.

Gas Chromatography. *System GA*—RI 1136; *system GI*—retention time 38.2 min.

Ultraviolet Spectrum. Methanol—289 nm ($A_1^1 = \text{about } 2$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1730, 1047, 1025, 1277, 1095, 755 (KCl disk).

Mass Spectrum. Principal peaks at m/z 95, 81, 41, 69, 55, 83, 67, 137.

Quantification. GAS CHROMATOGRAPHY. In plasma: detection limit 100 ng/ml, FID—R. C. Kelly *et al.*, *J. analyt. Toxicol.*, 1979, 3, 76–77.

Disposition in the Body. Absorbed after ingestion, through the mucous membranes and through the skin. Metabolised by hydroxylation and excreted in the urine mainly as the glucuronides of 2-hydroxy- and 3-hydroxycamphor. Oxidation also occurs at the 7-position yielding a small amount of a carboxylic acid.

TOXICITY. Poisoning by camphor has usually been due to ingestion of camphorated oil. The fatal dose in a one-year-old child is stated to be about 1 g of camphor although some children have survived the ingestion of 5 g. In adults, doses in the region of 2 g are likely to produce toxic symptoms and a dose of 4 g or more may be lethal, although a man has survived after ingestion of as much as 30 g in the form of 150 ml of camphorated oil. The maximum permissible atmospheric concentration is 2 ppm.

A plasma concentration of 1.7 µg/ml was reported in a severely intoxicated subject, 12 hours after the ingestion of about 18 g of camphor; the patient recovered after treatment by resin haemoperfusion (R. Kopelman *et al.*, *J. Am. med. Ass.*, 1979, 241, 727–728).

A serum concentration of 19.5 µg/ml was observed 7 hours after the ingestion of 0.7 g of camphor in a moderately intoxicated 3-year-old child (W. J. Phelan, *Pediatrics*, 1976, 57, 428–431).

Dose. Camphor was formerly given by mouth in doses of 120 to 300 mg.

Cannabis

Psychomimetic

Synonyms. Bhang; Cannabis Indica; Chanvre; Charas; Dagga; Ganja; Guaza; Hashish; Indian Hemp; Kif; Maconha; Marihuana.

Marihuana usually refers to a mixture of the leaves and flowering tops. *Bhang*, *dagga*, *ganja*, *kif*, and *maconha* are commonly used in various countries to describe similar preparations. *Hashish* and *charas* are names often applied to the resin, although in some countries hashish is applied to any cannabis preparation.

Note. Many other synonyms and approximate synonyms for cannabis and cannabis resin have been used—see *Martindale, The Extra Pharmacopoeia*, 28th Edn.

CAS—8063-14-7

The dried flowering or fruiting tops of the pistillate plant of *Cannabis sativa* (*Cannabinaceae*). In some countries, the legal definition includes the leaves and roots.

The active principles of the drug are present in the resin which contains about 30 derivatives of 2-(2-isopropyl-5-methylphenyl)-5-pentylresorcinol, known as cannabinoids. Considerable confusion exists in the nomenclature, depending on whether they are numbered as substituted monoterpenes or dibenzopyrans. To avoid confusion the dibenzofuran system is used in this volume.

dibenzofuran numbering:

Where appropriate, the alternative numbering system based on a substituted monoterpene structure is given in parentheses.

monoterpene numbering:

The most important cannabinoids are cannabidiol (CBD), cannabinol (CBN), (–)-*trans*-Δ⁹-tetrahydrocannabinol [Δ⁹-THC (Δ¹-THC)], (–)-*trans*-Δ⁸-tetrahydrocannabinol [Δ⁸-THC (Δ¹-THC)], and Δ⁹-tetrahydrocannabinolic acid.

Cannabidiol

Synonym. CBD

C₂₁H₃₀O₂ = 314.5

CAS—13956-29-1

White crystals. M.p. 66° to 67°.

Practically **insoluble** in water; readily soluble in chloroform and light petroleum.

Cannabinol

Synonym. CBN

C₂₁H₂₆O₂ = 310.4

CAS—521-35-7

White crystals. M.p. 76° to 77°.

Practically **insoluble** in water; readily soluble in chloroform and light petroleum.

Δ⁹-Tetrahydrocannabinol

Synonyms. Δ¹-THC; Δ⁹-THC; (–)-*trans*-Δ⁹-Tetrahydrocannabinol.

C₂₁H₃₀O₂ = 314.5

CAS—1972-08-3

A viscous oil.

Practically **insoluble** in water; soluble 1 in 1 of ethanol and 1 in 1 of acetone; readily soluble in chloroform and light petroleum.

Δ^8 -Tetrahydrocannabinol

Synonyms. Δ^1 - Δ^6 -THC; Δ^8 -THC; (–)-*trans*- Δ^8 -Tetrahydrocannabinol

$C_{21}H_{30}O_2 = 314.5$

CAS—5957-75-5

Practically **insoluble** in water; readily soluble in chloroform and light petroleum.

Δ^9 -Tetrahydrocannabinolic Acid

$C_{22}H_{30}O_4 = 358.5$

CAS—23978-85-0

The amount of the major constituents in various samples of cannabis varies between about 5% and zero, depending on climatic and genetic factors. Almost all the psychomimetic activity of the plant is associated with the Δ^9 -THC content, which is usually twenty times as great as that of Δ^8 -THC. The Δ^9 -THC content may average 1, 3, and 5% in marihuana, ganja, and hashish, respectively. Δ^9 -Tetrahydrocannabinolic acid, which is present in abundance in some cannabis samples, is itself inactive but it is converted by smoking into active Δ^9 -THC. Cannabinol and cannabidiol may be present in large amounts but have little activity.

Dissociation Constant. Δ^9 -THC, pK_a 10.6.

Colour Tests. *p*-Dimethylaminobenzaldehyde—red/violet (cannabinols); Duquenois Test—violet-blue/violet.

Thin-layer Chromatography. For information on the constituents of cannabis resin see Systems TI and TJ, p. 172.

Gas Chromatography. For information on the constituents of cannabis resin and on metabolites of Δ^9 -THC see Systems GA and GH, p. 197.

High Pressure Liquid Chromatography. For information on the constituents of cannabis resin see System HL, p. 217.

Ultraviolet Spectrum. Ethanol—cannabidiol 278 nm, cannabinol 285 nm, Δ^9 -THC 278 nm, Δ^9 -tetrahydrocannabinolic acid 278 nm and 283 nm.

Infra-red Spectrum. Main components have principal peaks at the following wavenumbers (all thin films):

Cannabidiol—1585, 1630, 1020, 1210, 1240, 1050

Cannabinol—1620, 1050, 1580, 1030, 1120, 1228

Δ^8 -THC—1580, 1030, 1620, 1180, 1080, 1260

Δ^9 -THC—1580, 1040, 1620, 1180, 1130, 1050

Cannabidiol

Cannabinol

Δ^8 -Tetrahydrocannabinol

Δ^9 -Tetrahydrocannabinol

Mass Spectrum. Main components and metabolites have principal peaks at the following m/z :

Cannabidiol—231, 246, 314, 232, 121, 193, 74, 174
 Cannabinol—295, 296, 238, 310, 119, 43, 251, 239
 Δ^8 -THC—221, 314, 248, 261, 193, 236, 222, 315
 Δ^9 -THC—299, 231, 314, 43, 41, 295, 55, 271
 8α -Hydroxy- Δ^9 -THC—271, 43, 41, 311, 295, 312, 297, 91
 8β -Hydroxy- Δ^9 -THC—271, 43, 295, 41, 297, 29, 330, 272
 11-Hydroxy- Δ^9 -THC—299, 43, 41, 67, 300, 69, 231, 29
 Δ^9 -THC-11-oic acid—41, 229, 43, 329, 69, 344, 29, 283

Quantification. GAS CHROMATOGRAPHY. In blood or brain tissues: Δ^9 -THC, detection limit 200 to 300 pg/ml in blood and 2.5 ng/g in brain samples, FID—N. K. McCallum and S. M. Shaw, *J. analyt. Toxicol.*, 1981, 5, 148–149.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In blood: Δ^9 -THC, initial screening by radioimmunoassay, detection limit 1 ng/ml—R. A. Bergman *et al.*, *J. analyt. Toxicol.*, 1981, 5, 85–89.

HIGH PRESSURE LIQUID CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma: Δ^9 -THC, detection limit 2.5 ng/ml—J. L. Valentine *et al.*, *J. pharm. Sci.*, 1977, 66, 1263–1266.

HIGH PRESSURE LIQUID CHROMATOGRAPHY–RADIOIMMUNOASSAY. In blood, plasma, serum, or urine: Δ^9 -THC and metabolites, sensitivity 6.5 ng/ml for plasma and 3.3 ng/ml for urine—B. Law *et al.*, *J. analyt. Toxicol.*, 1984, 8, 19–22.

RADIOIMMUNOASSAY. In body fluids: cannabinoid metabolites, sensitivity 10 ng/ml for blood and 2 ng/ml for urine—*idem*, 14–18.

Disposition in the Body. Δ^9 -THC is absorbed from the gastrointestinal tract but absorption is slow and irregular; bioavailability after ingestion is about 6 to 20% and during smoking is about 18%. Δ^9 -THC is lipophilic and is widely distributed in the body. It is oxidised to the active metabolites 11-hydroxy- Δ^9 -THC and 8β -hydroxy- Δ^9 -THC. The inactive substances 8α -hydroxy- Δ^9 -THC and $8\alpha,11$ -dihydroxy- Δ^9 -THC are also formed. 11-Hydroxy- Δ^9 -THC is further oxidised to 11-nor- Δ^9 -THC-9-carboxylic acid (Δ^9 -THC-11-oic acid), and many other polar mono- and di-carboxylic acids are formed; these are conjugated with glucuronic acid to a variable extent. Enterohepatic circulation of metabolites may occur. Up to about 25% of a dose is excreted in the urine in 3 days, mainly as 11-nor- Δ^9 -THC-9-carboxylic acid glucuronide, together with the other carboxylic acids in free and conjugated form. Δ^9 -THC-*O*-glucuronide has

also been detected in urine. The major excretion route is via the faeces, up to about 65% of a dose being excreted in 5 days, mainly as 11-hydroxy- Δ^9 -THC and the carboxylic acids in conjugated form. Δ^9 -THC metabolites have been detected in urine for up to 12 days following a single oral dose.

BLOOD CONCENTRATION.

After 11 subjects had smoked 11.6 to 15.6 mg (mean 13.0) of Δ^9 -THC from a cigarette over a period of 5 to 7 minutes, peak plasma concentrations of 0.03 to 0.12 $\mu\text{g/ml}$ (mean 0.08) of Δ^9 -THC were observed within 3 minutes after termination of smoking; the concentration fell rapidly to 0.003 to 0.01 $\mu\text{g/ml}$ (mean 0.007) at 1 hour and to 0.0006 to 0.003 $\mu\text{g/ml}$ (mean 0.0016) at 4 hours, after smoking. When 20 mg of Δ^9 -THC was given orally to the same subjects, peak plasma concentrations of 0.004 to 0.01 $\mu\text{g/ml}$ of Δ^9 -THC were produced between 60 and 300 minutes after ingestion (A. Ohlsson *et al.*, *Clin. Pharmac. Ther.*, 1980, 28, 409–416).

TOXICITY. Cannabis or Δ^9 -THC intoxication may result in loss of consciousness or even death, but reports of fatalities are rare. In one case of fatal poisoning by Δ^9 -THC, the following postmortem concentrations of Δ^9 -THC in tissues were reported: liver 37.5 $\mu\text{g/g}$, kidney 42 $\mu\text{g/g}$, and spleen 12 $\mu\text{g/g}$ (S. N. Tewari and J. D. Sharma, *Toxicol. Lett.*, 1980, 5, 279–281).

HALF-LIFE. Plasma half-life, Δ^9 -THC about 20 to 36 hours.

VOLUME OF DISTRIBUTION. Δ^9 -THC about 10 litres/kg.

DISTRIBUTION IN BLOOD. Plasma : whole blood ratio, Δ^9 -THC 1.8.

PROTEIN BINDING. In plasma, Δ^9 -THC and 11-hydroxy- Δ^9 -THC 94 to 99%.

NOTE. For a review of Δ^9 -THC metabolism and disposition see M. E. Wall and M. Perez-Reyes, *J. clin. Pharmac.*, 1981, 21, 178s–189s. See also M. E. Wall *et al.*, *Clin. Pharmac. Ther.*, 1983, 34, 352–363, and B. Law *et al.*, *J. Pharm. Pharmac.*, 1984, 36, 289–294.

Valentine and P. Psaltis, *Analyt. Lett. (Part B)*, 1979, 12, 855–866 and 867–880. Swabbing the hands for traces of marihuana—R. Thibault *et al.*, *J. forens. Sci.*, 1983, 28, 15–17.

Cantharidin

Vesicant

Proprietary Name. Cantharone

Hexahydro-3 α ,7 α -dimethyl-4 β ,7 β -epoxyisobenzofuran-1,3-dione

$\text{C}_{10}\text{H}_{12}\text{O}_4 = 196.2$

CAS—56-25-7

Cantharidin is obtained from cantharides, the dried beetle *Cantharis vesicatoria* (= *Lytta vesicatoria*) (Meloidae) or other spp., containing not less than 0.6%, or from mylabris, the dried beetles *Mylabris sidae* (= *M. phalerata*), *M. cichorii* and *M. pustulata* (Meloidae), containing not less than 1%.

Colourless, glistening crystals, which sublime at about 120°. M.p. 216° to 218°.

Very slightly **soluble** in water; soluble 1 in about 1100 of ethanol, 1 in 40 of acetone, 1 in 55 of chloroform, and 1 in 700 of ether.

Gas Chromatography. *System GA*—RI 1490.

Infra-red Spectrum. Principal peaks at wavenumbers 1242, 962, 900, 1786, 1852, 1002 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 128, 96, 70, 39, 41, 27, 42, 29.

Disposition in the Body. Readily absorbed from the skin and mucous membranes. It does not appear to be metabolised.

TOXICITY. When taken orally it causes great pain as well as blistering and gross inflammation of the gastro-intestinal tract, the kidneys and the bladder. The lethal dose is between 10 and 60 mg although a crystal weighing not more than 0.5 mg lodged in the mucosa might produce a blister which could be fatal.

A 27-year-old woman died about 17 hours after she had eaten coconut ice into which a small quantity of cantharidin had been introduced by a fellow employee. The postmortem findings revealed that between 65 and 130 mg of cantharidin was circulating in the organs. At the same time as the above incident a 19-year-old girl also ate a piece of the cantharidin-impregnated coconut ice. She died 26 hours later. The postmortem level of cantharidin in the organs was somewhat less than in the former case (L. C. Nickolls and D. Teare, *Br. med. J.*, 1954, 2, 1384).

Captodiamine

Tranquilliser

Synonym. Captodiamine

2-(4-Butylthiobenzhydrylthio)-*NN*-dimethylethylamine

$C_{21}H_{29}NS_2 = 359.6$

CAS—486-17-9

Captodiamine Hydrochloride

Proprietary Name. Covatine

$C_{21}H_{29}NS_2 \cdot HCl = 396.0$

CAS—904-04-1

Crystals. M.p. 131° to 132°.

Colour Tests. Mandelin's Test—violet; Marquis Test—violet.

Thin-layer Chromatography. *System TA*—Rf 66. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2774.

Ultraviolet Spectrum. Aqueous acid—266 nm ($A_1^1 = 370$ b); aqueous alkali—273 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 694, 751, 1086, 1041, 1010, 714 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 165, 255, 359, 166, 73, 199, 45.

Dose. Captodiamine hydrochloride has been given in doses of 150 mg daily.

Captopril

Antihypertensive

Proprietary Names. Acepril; Capoten; Lopirin.

1-[(2*S*)-3-Mercapto-2-methylpropionyl]-L-proline

$C_9H_{15}NO_3S = 217.3$

CAS—62571-86-2

A white crystalline powder. M.p. about 106°.

Freely **soluble** in water, ethanol, chloroform, and methanol.

Dissociation Constant. pK_a 3.7, 9.8.

Colour Tests. Palladium Chloride—orange; Sodium Nitroprusside (Method 2)—violet.

Thin-layer Chromatography. *System TD*—Rf 05; *system TE*—Rf 02; *system TF*—Rf 02. (Ferric chloride solution, yellow; mercuric chloride-diphenylcarbazone reagent, violet, turns pink on heating; acidified potassium permanganate solution, yellow; Van Urk reagent, yellow, fades on heating.)

Gas Chromatography. Decomposition occurs giving a single, broad and severely tailing peak.

Ultraviolet Spectrum. Aqueous acid—no significant absorption, 230 to 360 nm; aqueous alkali—238 nm ($A_1^1 = 235$ c).

Infra-red Spectrum. Principal peaks at wavenumbers 1589, 1742, 1202, 1192, 1229, 1245 (KBr disk). Polymorphism may occur.

Mass Spectrum. Principal peaks at m/z 70, 41, 69, 75, 114, 42, 217, 68.

Quantification. GAS CHROMATOGRAPHY. In plasma or blood: sensitivity 20 ng/ml for captopril in blood, 50 ng/ml for captopril and metabolites in plasma, ECD—M. S. Bathala *et al.*, *J. pharm. Sci.*, 1984, 73, 340–344.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma or urine: detection limits 1 ng/ml for captopril, 25 ng/ml for captopril disulphide—O. H. Drummer *et al.*, *J. Chromat.*, 1984, 305; *Biomed. Appl.*, 30, 83–93.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In blood or urine: sensitivity 5 ng/ml in blood and 100 ng/ml in urine, UV detection—Y. Kawahara *et al.*, *Chem. pharm. Bull.*, 1981, 29, 150–157. In plasma: detection limit 30 ng/ml, fluorescence detection—B. Jarrott *et al.*, *J. pharm. Sci.*, 1981, 70, 665–667.

RADIOIMMUNOASSAY. In plasma: sensitivity 2 ng/ml—F. M. Duncan *et al.*, *Clinica chim. Acta*, 1983, 131, 295–303.

Disposition in the Body. Readily absorbed after oral administration; about 75% of the dose is absorbed. Up to 40% of an oral dose is excreted in the urine as unchanged drug, about 3% as captopril disulphide and about 30% as polar metabolites. Excretion in the urine is rapid, about half the dose being excreted within the first 4 hours. An *S*-methyl metabolite has been identified in plasma and urine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 100 mg of ^{35}S -labelled captopril to 10 subjects, peak blood concentrations of 0.51 to 1.31 $\mu\text{g/ml}$ (mean 0.8) of captopril and 0.11 to 0.49 $\mu\text{g/ml}$ (mean 0.23) of captopril disulphide, were attained in 0.5 to 1.5 hours (K. J. Kripalani *et al.*, *Clin. Pharmac. Ther.*, 1980, 27, 636–641).

Following oral administration of 25 mg, three times a day to 12 subjects, a mean maximum steady-state blood concentration of 0.14 $\mu\text{g/ml}$ of captopril was reported 0.9 hour after a dose (R. J. Cody *et al.*, *Clin. Pharmac. Ther.*, 1982, 32, 721–726).

HALF-LIFE. Blood half-life, about 1 to 2 hours.

VOLUME OF DISTRIBUTION. In blood, about 0.7 litre/kg.

CLEARANCE. Blood clearance, about 13 ml/min/kg.

PROTEIN BINDING. In plasma, about 30%.

NOTE. For a review of captopril see J. A. Romankiewicz *et al.*, *Drugs*, 1983, 25, 6–40.

Dose. 75 to 150 mg daily; maximum of 450 mg daily.

Caramiphen

Anticholinergic

2-Diethylaminoethyl 1-phenylcyclopentane-1-carboxylate

$\text{C}_{18}\text{H}_{27}\text{NO}_2 = 289.4$

CAS—77-22-5

A liquid.

Caramiphen Edisylate

Synonym. Caramiphen Ethanedisulphonate

$\text{C}_{18}\text{H}_{27}\text{NO}_2 \cdot \frac{1}{2} \text{C}_2\text{H}_6\text{O}_6\text{S}_2 = 384.5$

CAS—125-86-0

Crystals. M.p. 115° to 116°.

Soluble in water and ethanol.

Caramiphen Hydrochloride

$\text{C}_{18}\text{H}_{27}\text{NO}_2 \cdot \text{HCl} = 325.9$

CAS—125-85-9

White crystals or crystalline powder. M.p. 142° to 146°.

Soluble 1 in 4 of water and 1 in 8 of ethanol; practically insoluble in ether.

Partition Coefficient. Log *P* (octanol), 2.3.

Colour Tests. Liebermann's Test—red-orange; Marquis Test—yellow; Sulphuric Acid (when warmed)—red.

Thin-layer Chromatography. System TA—Rf 66. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1971.

Ultraviolet Spectrum. Aqueous acid—252 nm ($A_1^1 = 7.9$ b), 259 nm ($A_1^1 = 7.9$ b), 265 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1718, 1154, 694, 1173, 1220, 1060 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 99, 91, 144, 58, 56, 41, 87.

Quantification. GAS CHROMATOGRAPHY. In blood: sensitivity < 2.5 ng/ml, AFID—P. Levandoski and T. Flanagan, *J. pharm. Sci.*, 1980, 69, 1353–1354.

Disposition in the Body.

THERAPEUTIC CONCENTRATION.

Following daily oral administration of 20 mg of caramiphen edisylate at 0, 4, and 8 hours to 11 subjects for 4 days, peak blood concentrations of 0.018 to 0.078 $\mu\text{g/ml}$ (mean 0.046) were reported 1 to 2 hours after a dose (P. Levandoski and T. Flanagan, *ibid.*).

Dose. Caramiphen hydrochloride has been given in doses of 50 to 600 mg daily.

Carbachol

Parasympathomimetic

Synonyms. Carbacholine; Carbamoylcholine Chloride; Carbamylcholine Chloride; Choline Chloride Carbamate.

Proprietary Names. Carbyl; Doryl; Miostat.

(2-Carbamoyloxyethyl)trimethylammonium chloride

$\text{C}_6\text{H}_{15}\text{ClN}_2\text{O}_2 = 182.6$

CAS—51-83-2

White or faintly yellow, hygroscopic, crystals or crystalline powder. M.p. 200° to 204°, with decomposition.

Soluble 1 in 1 of water and 1 in 50 of ethanol; very slightly soluble in dehydrated alcohol, more readily soluble on boiling; practically insoluble in acetone, chloroform, and ether.

Dissociation Constant. pK_a 4.8.

Thin-layer Chromatography. System TA—Rf 01. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1730, 1083, 1056, 930, 1102, 1200 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 58, 42, 44, 30, 129, 36, 143.

Dose. 6 mg daily by mouth. For acute symptoms, 250 μg by subcutaneous injection, repeated if necessary.

Carbamazepine

Anticonvulsant

Proprietary Names. Convuline; Tegretol; Timonil.

5*H*-Dibenz[*b,f*]azepine-5-carboxamideC₁₅H₁₂N₂O = 236.3

CAS—298-46-4

A white or yellowish-white crystalline powder. M.p. 189° to 193°.

Practically **insoluble** in water and ether; soluble 1 in 10 of ethanol and 1 in 10 of chloroform; soluble in acetone.

Colour Test. Dissolve the sample in 1 ml of chloroform, add 0.2 ml of *sodium hypobromite solution* and mix for 1 minute—blue-violet (detection limit 250 µg/ml).

Thin-layer Chromatography. System *TA*—Rf 60; system *TB*—Rf 04; system *TC*—Rf 56. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System *GA*—carbamazepine RI 2290, carbamazepine-10,11-epoxide RI 2030, iminostilbene RI 1930; system *GE*—carbamazepine retention time 0.83 relative to phenytoin; system *GF*—carbamazepine RI 2610, carbamazepine-10,11-epoxide RI 2560, iminostilbene RI 2620.

High Pressure Liquid Chromatography. System *HE*—k' 8.30.

Ultraviolet Spectrum. Methanol—237 nm, 285 nm ($A_1^1 = 490$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1678, 1594, 800, 769, 787, 1298 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 193, 192, 236, 191, 194, 165, 190, 237; carbamazepine-10,11-epoxide 180, 179, 178, 152, 44, 181, 223, 51; *trans*-10,11-dihydro-10,11-dihydroxycarbamazepine 180, 77, 181, 44, 179, 51, 209, 167.

Quantification. GAS CHROMATOGRAPHY. In plasma: carbamazepine and carbamazepine-10,11-epoxide, FID—A. Ranise *et al.*, *J. Chromat.*, 1981, 222; *Biomed. Appl.*, 11, 120–124. In plasma or urine: carbamazepine and other anticonvulsants,

detection limit 1 µg/ml, FID—R. Riva *et al.*, *J. Chromat.*, 1980, 221; *Biomed. Appl.*, 10, 75–84.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or saliva: carbamazepine and carbamazepine-10,11-epoxide, sensitivity 20 ng/ml for carbamazepine and 120 ng/ml for the metabolite in plasma, UV detection—J. J. MacKichan, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 373–383. In plasma or serum: carbamazepine and other anticonvulsants, sensitivity about 1 µg/ml, UV detection—J. A. Christofides and D. E. Fry, *Clin. Chem.*, 1980, 26, 499–501.

THIN-LAYER CHROMATOGRAPHY-SPECTROFLUORIMETRY. In serum: carbamazepine and two metabolites, detection limits 100 ng/ml for carbamazepine and 50 ng/ml for its metabolites—H. K. L. Hundt and E. C. Clark, *J. Chromat.*, 1975, 107, 149–154.

Disposition in the Body. Slowly but almost completely absorbed after oral administration; bioavailability greater than 70%. Metabolic reactions include epoxidation to form the 10,11-epoxide, which is active, followed by hydroxylation to *trans*-10,11-dihydro-10,11-dihydroxycarbamazepine; glucuronic acid conjugation also occurs. The rate of metabolism is higher in children than in adults. About 25% of a dose is excreted in the urine as the dihydroxy metabolite, together with 2% as the 10,11-epoxide and less than 10% as unchanged drug; other metabolites identified in the urine include carbamazepine-*N*-glucuronide, iminostilbene, and several monohydroxy- and trihydroxycarbamazepine isomers. About 30% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 4 to 12 µg/ml.

Following single oral doses of 200 mg given to 9 subjects, peak plasma concentrations of 7.8 to 14 µg/ml (mean 10) were attained in about 9 hours (M. Anttila *et al.*, *Eur. J. clin. Pharmac.*, 1979, 15, 421–425).

Steady-state plasma concentrations of 3 to 13 µg/ml (mean 8) for carbamazepine and 0.6 to 5.7 µg/ml (mean 3) for the epoxide metabolite, were reported in 24 subjects receiving daily oral doses of 8 to 30 mg/kg (J. J. MacKichan *et al.*, *Br. J. clin. Pharmac.*, 1981, 12, 31–37).

TOXICITY. The estimated minimum lethal dose is 5 g. Plasma concentrations of 2.4 to 6.0 to 10.5 µg/ml have been associated with slight toxic effects and concentrations of 3.2 to 10 to 21 µg/ml with severe toxicity.

In a fatality due to carbamazepine and ethanol intoxication, postmortem blood concentrations were: carbamazepine 53 µg/ml, ethanol 1930 µg/ml (M. Rousseau *et al.*, *Bull. int. Ass. forens. Toxicol.*, 1981, 16(1), 14–15).

In a fatality due to carbamazepine and alcohol, postmortem kidney and liver concentrations of 306 µg/g and 173 µg/g, respectively, of carbamazepine were reported; the blood-alcohol concentration was 1600 µg/ml (T. Borkowski and E. Janowska, *Bull. int. Ass. forens. Toxicol.*, 1983, 17(2), 16-17).

A 50-year-old man was admitted to hospital comatose 12 hours after the ingestion of an estimated 20 g of carbamazepine; a plasma concentration of 62 µg/ml was reported; he regained consciousness after 45 hours but remained confused for a further 4 days (P. J. Leslie *et al.*, *Br. med. J.*, 1983, 286, 1018).

HALF-LIFE. Plasma half-life, 18 to 65 hours (mean 35) after single doses; reduced during chronic treatment to about 10 to 30 hours for adults and 8 to 19 hours for children.

VOLUME OF DISTRIBUTION. About 1 litre/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 1.6.

SALIVA. Plasma: saliva ratio, about 3 to 5.

PROTEIN BINDING. In plasma, carbamazepine about 75% and 10,11-epoxycarbamazepine about 50%.

NOTE. For a review of the pharmacokinetics of carbamazepine see L. Bertilsson, *Clin. Pharmacokinet.*, 1978, 3, 128-143.

Dose. Initially 100 to 400 mg daily, increasing to 0.4 to 1.6 g daily.

Carbarson

Anti-amoebic

Synonym. Aminarsonum

4-Ureidophenylarsonic acid

$C_7H_9AsN_2O_4 = 260.1$

CAS—121-59-5

A white powder. M.p. 174°.

Soluble 1 in 330 of water and 1 in 400 of ethanol; very slightly soluble in chloroform and ether; soluble in solutions of alkali hydroxides and carbonates.

Ultraviolet Spectrum. Aqueous acid—257 nm; aqueous alkali—248 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1508, 1580, 1101, 903, 1681, 1248.

Dose. 500 to 750 mg daily, for 10 days.

Carbaryl

Insecticide

Synonym. Carbaril

Proprietary Names. Carylderm; Derbac (shampoo); Murvin; Sevin; Suleo-C.

1-Naphthyl methylcarbamate

$C_{12}H_{11}NO_2 = 201.2$

CAS—63-25-2

A white crystalline solid. M.p. 142°.

Practically **insoluble** in water; soluble in most polar organic solvents.

Colour Tests. Liebermann's Test—black→green; Marquis Test—green.

Gas Chromatography. Alphanaphthol (decomposition product): *system GA*—RI 1490; *system GK*—retention time 0.47 relative to caffeine.

Ultraviolet Spectrum. Ethanol—279 nm ($A_1^1 = 310$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1724, 1219, 1250, 1111, 781, 1265.

Mass Spectrum. Principal peaks at m/z 144, 115, 116, 57, 58, 63, 145, 89.

Quantification. GAS CHROMATOGRAPHY. In animal blood or tissues: detection limit 20 ng/ml for blood, 100 ng/ml for tissues, ECD—M. E. Mount and F. W. Oehme, *J. analyt. Toxicol.* 1980, 4, 286-292.

Carbazochrome

Haemostatic

Synonym. Adrenochrome Monosemicarbazone

Proprietary Names. Adrenoxyl; Cromosil.

5,6-Dihydro-3-hydroxy-1-methylindoline-5,6-dione 5-semicarbazone

$C_{10}H_{12}N_4O_3 = 236.2$

CAS—69-81-8

An oxidation product of adrenaline.

Yellowish-red or red crystals or crystalline powder. M.p. about 222°, with decomposition.

Very slightly **soluble** in water and ethanol; practically insoluble in ether.

Carbazochrome Salicylate*Proprietary Name.* Adrenosem Salicylate

A complex of carbazochrome with sodium salicylate

CAS—13051-01-9

A fine, orange-red, crystalline powder. M.p. 196° to 197.5°, with decomposition.

Soluble in water and ethanol.**Carbazochrome Sodium Sulphonate***Proprietary Names.* Adona; Emex. $C_{10}H_{11}N_4NaO_5S = 322.3$ *CAS*—51460-26-5

Orange to yellow, fine needle-like crystals. M.p. 227° to 228°, with decomposition.

Soluble 1 in 67 of cold water; slightly soluble in ethanol; practically insoluble in chloroform and ether.**Thin-layer Chromatography.** *System TD*—Rf 00; *system TE*—Rf 16; *system TF*—Rf 00.**Ultraviolet Spectrum.** Methanol—356 nm ($A_1^1 = 960$ b).**Mass Spectrum.** Principal peaks at m/z 147, 43, 146, 42, 193, 118, 164, 44.**Dose.** The equivalent of 5 to 10 mg of carbazochrome has been given intramuscularly or by mouth.**Carbenicillin***Antibiotic**Synonym.* α -Carboxybenzylpenicillin(6*R*)-6-(2-Carboxy-2-phenylacetamido)penicillanic acid $C_{17}H_{18}N_2O_6S = 378.4$ *CAS*—4697-36-3**Carbenicillin Sodium***Proprietary Names.* Anabactyl; Carbapen; Fugacillin; Geopen; Microcilin; Pyopen. $C_{17}H_{16}N_2Na_2O_6S = 422.4$ *CAS*—4800-94-6

A white, hygroscopic, crystalline powder.

Soluble 1 in 1.2 of water and 1 in 25 of ethanol; practically insoluble in chloroform and ether.**Dissociation Constant.** pK_a 2.6, 2.7.**Ultraviolet Spectrum.** Aqueous acid—259 nm, 265 nm, 327 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1612, 1754, 1315, 1123, 1030, 1000.**Dose.** The equivalent of 20 to 30 g of carbenicillin daily, intravenously.**Carbenoxolone***Treatment of Peptic Ulcer**Synonyms.* Glycerrhetic Acid Hydrogen Succinate; Glycyrrhetic Acid Hydrogen Succinate.3 β -(3-Carboxypropionyloxy)-11-oxo-olean-12-en-30-oic acid $C_{34}H_{50}O_7 = 570.8$ *CAS*—5697-56-3

Cream-coloured crystals. M.p. 291° to 294°.

Carbenoxolone Sodium*Synonym.* Disodium Enoxolone Succinate*Proprietary Names.* Biogastrone; Duogastrone; Gastrausil; Neogel; Ulcus-Tablinen. It is an ingredient of Pyrogastrone. $C_{34}H_{48}Na_2O_7 = 614.7$ *CAS*—7421-40-1

A white or pale cream-coloured hygroscopic powder.

Soluble 1 in 6 of water and 1 in 30 of ethanol; practically insoluble in chloroform and ether.**Caution.** Carbenoxolone sodium powder is irritating to nasal membranes.**Dissociation Constant.** pK_a 6.7, 7.1.**Colour Tests.** Antimony Pentachloride—brown; Naphthol-Sulphuric Acid—yellow-brown/orange; Sulphuric Acid—yellow.

Mix 5 mg with 50 mg of resorcinol and 2 ml of 80% v/v sulphuric acid, heat at 200° for 10 minutes, cool, and add to 200 ml of water; make just alkaline with *sodium hydroxide solution*—an intense green fluorescence is produced.

Thin-layer Chromatography. *System TD*—Rf 07; *system TE*—Rf 00; *system TF*—Rf 17. (*Acidified potassium permanganate solution*, positive, faint.)

Ultraviolet Spectrum. Carbenoxolone sodium: aqueous acid—248 nm; aqueous alkali—257 nm ($A_1^1 = 172$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1562, 1642, 1715, 1289, 1261, 1210 (carbenoxolone sodium, KBr disk).

Quantification. GAS CHROMATOGRAPHY. In serum: sensitivity 5 µg/ml, FID—C. Rhodes and P. A. Wright, *J. Pharm. Pharmac.*, 1974, 26, 894–898.

RADIOIMMUNOASSAY. In serum: sensitivity 1 ng/ml—B. M. Peskar *et al.*, *J. Pharm. Pharmac.*, 1976, 28, 720–721.

Disposition in the Body. Rapidly and almost completely absorbed after oral administration; absorption is reduced at gastric pH levels above 2 and delayed after food. It is almost entirely eliminated in the faeces via the bile, less than 5% being excreted in the urine. Carbenoxolone is excreted mainly as the glucuronide conjugate together with small amounts as the sulphate conjugate of β -glycyrrhetic acid (enoxolone).

THERAPEUTIC CONCENTRATION.

After a single oral dose of 200 mg to 10 subjects, peak blood concentrations of 13 to 35 µg/ml (mean 24) were attained in 1 to 2 hours, followed by a second peak of 3 to 32 µg/ml (mean 20) at 3 to 6 hours; in some subjects, the second peak was higher than the first (H. D. Downer *et al.*, *J. Pharm. Pharmac.*, 1970, 22, 479–487).

Following oral administration of 100 mg to 3 fasting subjects, peak serum concentrations of 15 to 20 µg/ml were attained in 1 to 2 hours; following administration of 100 mg to 2 subjects after meals, peak serum concentrations of 8 to 9 µg/ml were reported at 5 to 6 hours.

After oral doses of 100 mg three times a day to 9 subjects, serum concentrations of 20 to 98 µg/ml (mean 49) were reported on the 8th day (J. H. Baron *et al.*, Factors affecting the Absorption of Carbenoxolone in Patients with Peptic Ulcer, in *4th Symposium on Carbenoxolone*, F. A. Jones and D. V. Parke (Ed.), London, Butterworths, 1975, pp. 115–124).

HALF-LIFE. Plasma half-life 8 to 20 hours (mean 13), increased in elderly subjects.

VOLUME OF DISTRIBUTION. About 0.1 litre/kg.

PROTEIN BINDING. In plasma, more than 99%.

NOTE. For a review of carbenoxolone see R. M. Pinder *et al.*, *Drugs*, 1976, 11, 245–307.

Dose. 150 to 300 mg of carbenoxolone sodium daily.

Carbetapentane

Cough Suppressant

Synonym. Pentoxiverine

2-(2-Diethylaminoethoxy)ethyl 1-phenylcyclopentane-1-carboxylate

$C_{20}H_{31}NO_3 = 333.5$

CAS—77-23-6

Carbetapentane Citrate

Proprietary Names. Atussil; Germapect; Sedotussin; Toclate; Tuclase; Tussa-Tablinen.

$C_{20}H_{31}NO_3 \cdot C_6H_8O_7 = 525.6$

CAS—23142-01-0

A white crystalline powder. M.p. 90° to 95°.

Very **soluble** in water and chloroform; soluble in ethanol; practically insoluble in ether.

Colour Tests. Liebermann's Test—red-orange; Mandelin's Test—brown (slow); Marquis Test—orange (slow).

Thin-layer Chromatography. *System TA*—Rf 48; *system TB*—Rf 48; *system TC*—Rf 22. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *Marquis reagent*, brown.)

Gas Chromatography. *System GA*—RI 2232; *system GF*—RI 2455.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm ($A_1^1 = 6.1$ a), 264 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1725, 1120, 1158, 1176, 694, 1234, (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 91, 87, 145, 58, 144, 30, 44.

Dose. 25 to 150 mg of carbetapentane citrate daily.

Carbidopa*Dopa-decarboxylase Inhibitor**Synonym.* (–)-L- α -Methyldopa Hydrazine*Proprietary Name.* It is an ingredient of Sinemet.*S-2-(3,4-Dihydroxybenzyl)-2-hydrazinopropionic acid monohydrate* $C_{10}H_{14}N_2O_4 \cdot H_2O = 244.2$ *CAS*—28860-95-9 (anhydrous); 38821-49-7 (monohydrate)

A white or creamy-white powder. M.p. about 210°, with decomposition.

Soluble 1 in 500 of water; practically insoluble in ethanol, chloroform, and ether; freely soluble in 3M hydrochloric acid.

Colour Tests. Ammoniacal Silver Nitrate (on warming)—silver mirror; Ferric Chloride—brown; Folin-Ciocalteu Reagent—blue; Liebermann's Test—black; Marquis Test—brown; Methanolic Potassium Hydroxide—orange; Millon's Reagent (cold)—orange; Nessler's Reagent—orange→black; Palladium Chloride—orange→brown; Potassium Dichromate (Method 1)—red.

Thin-layer Chromatography. *System TD*—Rf 00; *system TE*—Rf 00; *system TF*—Rf 02.

Ultraviolet Spectrum. Methanolic acid—282 nm ($A_1^1 = 130$ a); aqueous alkali—291 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1625, 1121, 1260, 1525, 1290, 875 (KBr disk).

Mass Spectrum. Principal peaks at m/z 123, 57, 42, 103, 44, 85, 124, 51.

Wavelength

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 15 ng/ml, electrochemical detection—E. Nissinen and J. Taskinen, *J. Chromat.*, 1982, 231; *Biomed. Appl.*, 20, 459–462.

Disposition in the Body. Readily but incompletely absorbed after oral administration. About 50% of an oral dose is excreted in the urine in 48 hours and 47% is eliminated in the faeces. Of the urinary material, about 30% is unchanged drug, 10 to 14% is 2-(4-hydroxy-3-methoxybenzyl)propionic acid, 10% is 2-(3,4-dihydroxybenzyl)propionic acid, 5% is 3,4-dihydroxyphenylacetone and 10% is 2-(3-hydroxybenzyl)propionic acid. The metabolites are excreted mainly as glucuronide conjugates.

THERAPEUTIC CONCENTRATION.

Following an oral dose of 50 mg to 10 subjects, a mean peak plasma concentration of 0.2 μ g/ml was attained in 2 to 4 hours (S. Vickers *et al.*, *Drug Met. Disp.*, 1974, 2, 9–22).

HALF-LIFE. Plasma half-life, about 2 hours.

PROTEIN BINDING. In plasma, about 36%.

NOTE. For a review of the pharmacokinetics of carbidopa see R. M. Pinder *et al.*, *Drugs*, 1976, 11, 329–377.

Dose. Usually the equivalent of 75 to 150 mg of anhydrous carbidopa daily, given in combination with levodopa.

Carbimazole*Antithyroid Agent*

Proprietary Names. Carbazole; Carbtiroid; Neo-Mercazole; Neo-Morphazole; Neo-Thyreostat; Neo-Tireol.

Ethyl 3-methyl-2-thioxo-4-imidazoline-1-carboxylate

 $C_7H_{10}N_2O_2S = 186.2$ *CAS*—22232-54-8

A white or creamy-white crystalline powder. M.p. 122° to 125°.

Soluble 1 in 500 of water, 1 in 50 of ethanol, 1 in 17 of acetone, 1 in 3 of chloroform, and 1 in 330 of ether.

Colour Tests. Palladium Chloride—orange.

To a small quantity add 1 drop of *iodobismuthous acid solution*—red.

Thin-layer Chromatography. System TA—Rf 72; system TD—Rf 63; system TE—Rf 47; system TF—Rf 48. (Acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—carbamazole RI 1678, methimazole RI 1550.

Ultraviolet Spectrum. Aqueous acid—291 nm ($A_1^1 = 557$ a); aqueous alkali—244 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1574, 1275, 740, 1246, 1150, 767 (KBr disk).

Mass Spectrum. Principal peaks at m/z 186, 114, 29, 72, 42, 113, 27, 109; methimazole 114, 42, 72, 113, 69, 81, 54, 115.

Quantification. GAS CHROMATOGRAPHY. In plasma: methimazole, limit of detection 30 ng/ml, AFID—M. R. Bending and D. Stevenson, *J. Chromat.*, 1978, 154, 267–271.

GAS CHROMATOGRAPHY-MASS SPECTROMETRY. In plasma: methimazole, sensitivity 2 ng/ml—S. Floberg *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 63–70.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: methimazole, limit of detection 5 ng/ml, absorbance detection at 405 nm—A. Meulemans *et al.*, *J. liq. Chromat.*, 1980, 3, 287–298.

Disposition in the Body. Rapidly and almost completely absorbed after oral administration and converted to the active metabolite methimazole. Almost completely excreted in the urine in 24 hours as metabolites; 3-methyl-2-thiohydantoin has been identified as a minor metabolite in urine and plasma. About 3% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After an oral dose of 60 mg, given to 11 subjects, peak serum concentrations of methimazole of 0.5 to 3.4 $\mu\text{g/ml}$ (mean 0.9) were attained in about 0.7 to 3 hours (A. Melander *et al.*, *Eur. J. clin. Pharmac.*, 1980, 17, 295–299).

HALF-LIFE. Plasma half-life, methimazole about 3 to 5 hours.

VOLUME OF DISTRIBUTION. Methimazole, about 0.5 litre/kg.

PROTEIN BINDING. In plasma, methimazole, not significantly bound.

NOTE. For a review of the pharmacokinetics of antithyroid drugs, see J. P. Kampmann and J. M. Hansen, *Clin. Pharmacokin.*, 1981, 6, 401–428.

Dose. Initially 30 to 60 mg daily; maintenance, 5 to 20 mg daily.

Carbinoxamine

Antihistamine

2-[4-Chloro- α -(2-pyridyl)benzyloxy]-*NN*-dimethylethylamine

$\text{C}_{16}\text{H}_{19}\text{ClN}_2\text{O} = 290.8$

CAS—486-16-8

A liquid.

Carbinoxamine Maleate

Proprietary Names. Allergefon; Clistin; Histex; Ziriton. It is an ingredient of Davenol, Extil, and Rondec.

$\text{C}_{16}\text{H}_{19}\text{ClN}_2\text{O}_4 \cdot \text{C}_4\text{H}_4\text{O}_4 = 406.9$

CAS—3505-38-2

A white crystalline powder. M.p. 116° to 121° .

Soluble 1 in less than 1 of water, 1 in 1.5 of ethanol, and 1 in 1.5 of chloroform; very slightly soluble in ether.

Dissociation Constant. pK_a 8.1 (25°).

Colour Test. Cyanogen Bromide—orange-pink.

Thin-layer Chromatography. System TA—Rf 48; system TB—Rf 25; system TC—Rf 19. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, pink.)

Gas Chromatography. System GA—RI 2080; system GB—RI 2090; system GC—RI 2430.

High Pressure Liquid Chromatography. System HA— k' 4.7 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—263 nm ($A_1^1 = 323$ a); aqueous alkali—261 nm ($A_1^1 = 181$ a) (See below).

Infra-red Spectrum. Principal peaks at wavenumbers 1084, 1110, 1584, 1041, 763, 1010 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 71, 26, 54, 167, 72, 42, 44.

Quantification. GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In plasma: sensitivity 200 pg/ml, AFID—D. J. Hoffman *et al.*, *J. pharm. Sci.*, 1983, 72, 1342–1344.

Dose. 12 to 32 mg of carbinoxamine maleate daily.

Carbon Tetrachloride *Anthelmintic (Veterinary)/Solvent*

Synonym. Carboneum Tetrachloratum Medicinale

Tetrachloromethane

$\text{CCl}_4 = 153.8$

CAS—56-23-5

A heavy, clear, colourless, volatile liquid, with a chloroform-like odour. It is non-inflammable but in contact with a flame it decomposes and gives rise to toxic products, which have an acrid odour. Wt per ml 1.592 to 1.595 g. B.p. 76° to 78° . Refractive index 1.4607.

Soluble 1 in 1500 of water; miscible with dehydrated alcohol, chloroform, and ether.

Colour Test. Fujiwara Test—red.

Gas Chromatography. System GA—RI 659; system GI—retention time 8.6 min.

Mass Spectrum. Principal peaks at m/z 117, 119, 47, 35, 121, 82, 84, 49.

Quantification. GAS CHROMATOGRAPHY. In biological material and expired air: simultaneous determination of carbon tetrachloride and chloroform, sensitivity $5\mu\text{g}$ by FID, 15 ng by ECD—C. J. Reddrop *et al.*, *J. Chromat.*, 1980, 193, 71–82.

Disposition in the Body. Readily absorbed after inhalation and also absorbed after ingestion or through the skin; the rate of absorption is increased by the concomitant ingestion of alcohol. It is excreted mainly from the lungs as carbon tetrachloride and carbon dioxide; excretion in the urine as urea and an unidentified metabolite, and elimination in the faeces also occur.

TOXICITY. The minimum lethal dose is 3 to 5 ml but recoveries have occurred following ingestion of 30 to 40 ml. Carbon tetrachloride injures almost all cells of the body including those of the blood, central nervous system, liver and kidney; the kidneys and liver of fatal cases often show marked fatty degeneration. The maximum permissible atmospheric concentration is 10 ppm. Inhalation of concentrations of 1000 ppm, even for short periods, may cause acute toxic reactions. Continued exposure to concentrations of about 100 ppm may give rise to chronic poisoning. When carbon tetrachloride is ingested together or immediately after alcohol, its toxicity, particularly nephrotoxicity, is greatly increased. Toxic effects are associated with blood concentrations of 20 to $50\mu\text{g/ml}$ and a postmortem blood concentration of $260\mu\text{g/ml}$ has been reported in one fatality.

A middle-aged alcoholic ingested about 30 ml of carbon tetrachloride under the impression that it was alcohol. He was seriously ill but recovered. On his admission to hospital the serum concentration of carbon tetrachloride was $20\mu\text{g/ml}$. The first 24-hour urine collection contained $8\mu\text{g/ml}$ and the first peritoneal dialysate contained $1\mu\text{g/ml}$ of carbon tetrachloride (S. L. Tompsett, personal communication, 1967).

The following postmortem tissue concentrations were reported in a fatality due to the inhalation of carbon tetrachloride: kidney $32\mu\text{g/g}$, liver $142\mu\text{g/g}$, lung $39\mu\text{g/g}$, muscle $46\mu\text{g/g}$ (H. D. Korenke and O. Pribilla, *Arch. Tox.*, 1969, 25, 109–126).

The following postmortem tissue concentrations were reported in a fatality due to inhalation of carbon tetrachloride: blood $18\mu\text{g/ml}$, brain $175\mu\text{g/g}$, lung $12.5\mu\text{g/g}$ (A. Franc, *Bull. int. Ass. forens. Toxicol.*, 1983, 17(2), 22–25).

Carbromal

Hypnotic

Synonyms. Bromadal; Bromodiethylacetylurea; Karbromal; Uradal.

Proprietary Names. Adalin; Mirfudorm.

N-(2-Bromo-2-ethylbutyryl)urea

$\text{C}_7\text{H}_{13}\text{BrN}_2\text{O}_2 = 237.1$

CAS—77-65-6

A white crystalline powder. M.p. 117° to 120° .

Soluble 1 in 3000 of water, 1 in 18 of ethanol, 1 in 2 of chloroform, and 1 in 25 of ether.

Colour Test. Nessler's Reagent—brown-orange.

Thin-layer Chromatography. System TD—Rf 53; system TE—Rf 74; system TF—Rf 56. (Fluorescein solution, pink.)

Gas Chromatography. System GA—carbromal RI 1513, 2-bromo-2-ethylbutyramide RI 1205, 2-bromo-2-ethyl-3-hydroxybutyramide RI 1340, 2-ethylbutyrylurea RI 1380.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1694, 660, 1600, 1094, 1212, 834 (KBr disk).

Mass Spectrum. Principal peaks at m/z 44, 69, 41, 208, 210, 55, 71, 43; 2-bromo-2-ethylbutyramide 69, 43, 41, 44, 71, 167, 165, 55; 2-bromo-2-ethyl-3-hydroxybutyramide 150, 152, 165, 41, 167, 43, 44, 130; 2-ethylbutyrylurea 45, 130, 44, 71, 42, 61, 115, 55.

Carbutamide

Antidiabetic

Synonym. Glybutamide

Proprietary Names. Diabetoplex; Dia-Tablinen; Glucidoral; Insoral; Invenol; Nadisan.

Note. Insoral is also used as a proprietary name for phenformin hydrochloride.

1-Butyl-3-sulphanilylurea

$C_{11}H_{17}N_3O_3S = 271.3$

CAS—339-43-5

Quantification. GAS CHROMATOGRAPHY. In blood: determined as inorganic bromide, FID—J. Wells and G. Cimbura, *J. forens. Sci.*, 1973, 18, 437–440.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: carbromal, 2-bromo-2-ethylbutyramide and 2-ethylbutyrylurea, sensitivity 200 ng/ml for carbromal, UV detection—M. Eichelbaum *et al.*, *Arch. Tox.*, 1978, 41, 187–193.

Disposition in the Body. Readily absorbed after oral administration. The major metabolite is free bromide ion; hydrolysis to an active metabolite, 2-bromo-2-ethylbutyramide, also occurs followed by oxidation to 2-bromo-2-ethyl-3-hydroxybutyramide; other metabolites include 2-ethylbutyrylurea and 2-ethyl-2-hydroxybutyric acid. Carbromal is excreted in the urine mainly as bromide ion and partly as 2-ethyl-2-hydroxybutyric acid, with very little as unchanged drug. Peak bromide excretion is attained after about 48 hours.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 1 g given to 4 subjects, mean peak serum concentrations of about 6 μg/ml of carbromal and 3 μg/ml of 2-bromo-2-ethylbutyramide were attained in 0.5 and 4 hours respectively; the total bromide concentration reached about 12 μg/ml in 9 hours and was still increasing (H. W. Vohland *et al.*, *Arch. Tox.*, 1976, 36, 31–42).

TOXICITY. Fatalities have occurred in adults following the ingestion of 10 to 25 g but they are rare. Long-term use of carbromal may give rise to symptoms of chronic toxicity resembling bromism. Toxic effects are associated with serum-bromide concentrations of 300 to 1200 to 3200 μg/ml.

In 11 fatalities attributed to carbromal overdose, the following postmortem tissue concentrations, μg/ml or μg/g (mean, n), were reported:

	Carbromal	Bromoethylbutyramide
Blood	19.9–26.1 (23, 3)	0.2–27.2 (15, 10)
Brain	0.6–120.9 (45, 8)	23.3–118.4 (66, 11)
Kidney	0.4–13 (6, 4)	16.1–79.6 (45, 9)
Liver	1.1–2.8 (2.3, 4)	1.75–50.5 (14, 9)
Urine	0.85–47.4 (24, 5)	2.5–36.9 (23, 8)

Total bromide concentrations in the blood ranged from 145 to 1898 μg/ml (mean 536) (H. Kaferstein and G. Sticht, *Z. Rechtsmed.*, 1978, 81, 269–283).

Postmortem serum-carbromal concentrations of 158 and 71 μg/ml were found in 2 fatalities resulting from acute intoxication (H. Gruska *et al.*, *Arch. Tox.*, 1970, 26, 149–160, and 1971, 28, 149–158).

HALF-LIFE. Plasma half-life, carbromal 7 to 15 hours, bromide about 15 days.

Dose. 0.3 to 1 g, as a hypnotic.

A white finely crystalline powder. M.p. 144° to 145°.

Practically **insoluble** in water, chloroform, and ether; soluble in ethanol and acetone.

Dissociation Constant. pK_a 6.0 (20°).

Thin-layer Chromatography. System TA—Rf 78; system TT—Rf 90; system TU—Rf 27; system TV—Rf 07.

Ultraviolet Spectrum. Aqueous acid—266 nm ($A_1^1 = 149$ a); aqueous alkali—255 nm ($A_1^1 = 616$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1661, 1147, 1599, 1089, 1635, 1310 (KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: UV detection—F. Saffar *et al.*, *Chem. pharm. Bull.*, 1982, 30, 679–683.

Disposition in the Body. Absorbed after oral administration. It is excreted in the urine mainly as the acetyl derivative.

THERAPEUTIC CONCENTRATION.

Following an oral dose of 250 mg to 5 subjects, a mean peak serum concentration of 48.8 μg/ml was reported at 2.6 hours (F. Saffar *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, about 24 hours.

REFERENCE. F. Saffar *et al.*, *ibid.*

Dose. Carbutamide has been given in doses of 0.5 to 1 g daily.

Carisoprodol*Muscle Relaxant**Synonym.* *N*-Isopropylmeprobamate*Proprietary Names.* Carisoma; Flexartal; Mioxom; Rela; Sanoma; Soma; Somadril.*Note.* The name Soma has also been applied to an hallucinogenic fungus.

2-Methyl-2-propyltrimethylene carbamate isopropylcarbamate

 $C_{12}H_{24}N_2O_4 = 260.3$

CAS—78-44-4

A white crystalline powder. M.p. 92° to 94°.

Soluble 1 in 3300 of water; soluble in most common organic solvents.**Thin-layer Chromatography.** *System TD*—Rf 36; *system TE*—Rf 73; *system TF*—Rf 53. (Furfuraldehyde reagent, positive.)**Gas Chromatography.** *System GA*—carisoprodol RI 1830, meprobamate RI 1796.**Ultraviolet Spectrum.** No significant absorption, 230 to 360 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1695, 1527, 1075, 1246, 1101, 1319 (Nujol mull).**Mass Spectrum.** Principal peaks at m/z 55, 57, 43, 97, 41, 56, 158, 44; meprobamate 83, 84, 55, 56, 43, 71, 41, 62 (no peaks above 160).**Quantification.** GAS CHROMATOGRAPHY. In serum or urine: carisoprodol and meprobamate, FID—H. R. Adams *et al.*, *J. forens. Sci.*, 1975, 20, 200–202. In biological fluids and tissues—R. Maes *et al.*, *Eur. J. Toxicol.*, 1970, 3, 140–143.**Disposition in the Body.** Absorbed after oral administration. It is metabolised principally to meprobamate, which is active, and to hydroxymeprobamate and their glucuronide conjugates. Less than 1% of a dose is excreted in the urine as unchanged drug in 24 hours and about 5% is excreted as meprobamate in the same period.**TOXICITY.**The following concentrations were reported 4.5 hours after the ingestion of 3.5 g by a young child: blood, carisoprodol 36.4 µg/ml, meprobamate 15 µg/ml; urine, carisoprodol 24.4 µg/ml, meprobamate 166.4 µg/ml; the child's condition deteriorated and death occurred within 36 hours (H.R. Adams *et al.*, *J. forens. Sci.*, 1975, 20, 200–202).The following postmortem tissue concentrations were reported in a suicide case: blood 110 µg/ml, bile 64 µg/ml, kidney 110 µg/g, liver 127 µg/g, urine 165 µg/ml (R. Maes *et al.*, *J. forens. Sci.*, 1969, 14, 235–254).**Dose.** 1.05 to 1.4 g daily.**Carphenazine***Tranquilliser**Synonym.* Carfenazine

1-(10-{3-[4-(2-Hydroxyethyl)piperazin-1-yl]propyl}phenothiazin-2-yl)propan-1-one

 $C_{24}H_{31}N_3O_2S = 425.6$

CAS—2622-30-2

**Carphenazine Maleate***Proprietary Name.* Proketazine $C_{24}H_{31}N_3O_2S_2C_4H_4O_4 = 657.7$

CAS—2975-34-0

A fine yellow powder. M.p. 176° to 185°, with decomposition.

Soluble 1 in 600 of water and 1 in 400 of ethanol; practically insoluble in chloroform and ether.**Colour Tests.** Formaldehyde-Sulphuric Acid—blue; Forrest Reagent—red; FPN Reagent—red-orange; Liebermann's Test—red-brown; Mandelin's Test—red-violet; Marquis Test—orange → red-violet.**Thin-layer Chromatography.** *System TA*—Rf 54; *system TB*—Rf 05; *system TC*—Rf 27. (Acidified iodoplatinate solution, positive.)**Gas Chromatography.** *System GA*—RI 3590.**High Pressure Liquid Chromatography.** *System HA*— k' 1.7.**Ultraviolet Spectrum.** Aqueous acid—243 nm ($A_1^1 = 606$ a), 277 nm. No alkaline shift.**Infra-red Spectrum.** Principal peaks at wavenumbers 1585, 1557, 1666, 1204, 751, 1298 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 268, 143, 425, 70, 269, 42, 394, 157.**Dose.** 75 to 400 mg of carphenazine maleate daily.

Cathine*Anorectic*

Synonyms. Katine; (+)-Norpseudoephedrine; Pseudonorephedrine.

threo-2-Amino-1-phenylpropan-1-ol

$C_9H_{13}NO = 151.2$

CAS—492-39-7; 36393-56-3

An alkaloid obtained from catha, the fresh or dried leaves of *Catha edulis* (Celastraceae). Catha (also known as Abyssinian, African, or Arabian Tea; Kat; Kath; Khat; Miraa) is used in northern and eastern Africa as a stimulant, the leaves either being chewed or used as an infusion.

Crystals. M.p. 77° to 78°.

Soluble in ethanol, chloroform, and ether.

Cathine Hydrochloride

Proprietary Names. Adiposetten N; Amorphan Depot.

$C_9H_{13}NO \cdot HCl = 187.7$

CAS—2153-98-2

Crystals. M.p. 180° to 181°.

Soluble in water.

Dissociation Constant. pK_a 9.4.

Thin-layer Chromatography. System TA—Rf 42; system TB—Rf 25; system TC—Rf 05. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—RI 1302; system GB—RI 1362; system GC—RI 1383.

High Pressure Liquid Chromatography. System HA— k' 1.0; system HB— k' 4.39; system HC— k' 0.83.

Ultraviolet Spectrum. Aqueous acid—252 nm, 258 nm ($A_1^1 = 10$ a), 263 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1045, 695, 754, 704, 1091, 976 (KBr disk).

Mass Spectrum. Principal peaks at m/z 44, 57, 43, 40, 55, 41, 79, 77.

Wavelength

Disposition in the Body. About 40% of an ingested dose is excreted unchanged in the urine in 6 hours.

Cathine is a metabolite of pseudoephedrine.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 60 mg to 6 subjects, a mean peak plasma concentration of 0.2 µg/ml was attained in 1.3 hours; cathine could not be detected in the plasma after 24 hours (F. Frosch, *Arzneimittel-Forsch.*, 1977, 27, 665–668).

TOXICITY. Addiction to catha has been reported.

HALF-LIFE. Plasma half-life, about 3 hours.

Dose. Cathine hydrochloride has been given in doses of 20 to 60 mg daily.

Cephaeline*Emetic/Expectorant*

Synonym. Desmethylemetine

7',10,11-Trimethoxyemetan-6'-ol

$C_{28}H_{38}N_2O_4 = 466.6$

CAS—483-17-0

An alkaloid present in ipecacuanha, the dried root, or rhizome and root, of *Cephaelis ipecacuanha* (= *Uragoga ipecacuanha*) (Rubiaceae) or *C. acuminata*.

Needles. M.p. 115° to 116°.

Practically **insoluble** in water; soluble in ethanol and chloroform; slightly soluble in ether.

Cephaeline Hydrochloride

$C_{28}H_{38}N_2O_4 \cdot 2HCl = 539.5$

CAS—5853-29-2

White crystals or crystalline powder. Solutions turn yellow.

Soluble in water, ethanol, acetone, and chloroform.

Colour Test. Liebermann's Test—black.

Thin-layer Chromatography. System *TA*—Rf 53; system *TB*—Rf 01; system *TC*—Rf 19. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. System *HA*—*k'* 7.7 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—283 nm ($A_1^1 = 127$ b); ethanol—235 nm, 276 nm ($A_1^1 = 144$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1264, 1515, 1116, 1229, 1213, 1616 (cephaeline hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at *m/z* 178, 192, 272, 466, 244, 288, 191, 273.

Quantification. See under Emetine.

Dose. Cephaeline hydrochloride has been given in doses of 5 to 10 mg.

Cephalexin

Antibiotic

Synonym. Cefalexin

Proprietary Names. Ceporex; Ceporex(e); Keflex; Keforal; Oracef.

(7*R*)-3-Methyl-7-(α -D-phenylglycylamino)-3-cephem-4-carboxylic acid monohydrate

$C_{16}H_{17}N_3O_4S \cdot H_2O = 365.4$

CAS—15686-71-2 (anhydrous); 23325-78-2 (monohydrate)

A white to cream-coloured, slightly hygroscopic, crystalline powder.

Soluble 1 in 100 of water and 1 in 30 of 0.2% hydrochloric acid; practically insoluble in ethanol, chloroform, and ether; soluble in solutions of dilute alkalis.

Dissociation Constant. pK_a 2.5, 5.2, 7.3.

Ultraviolet Spectrum. Aqueous acid—258 nm; water—260 nm ($A_1^1 = 232$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1754, 1582, 1681, 1271, 695, 1186 (KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. Review of methods for the analysis of antibiotics in biological fluids—I. Nilsson-Ehle, *J. liq. Chromat.*, 1983, 6, 251–293.

Dose. 1 to 6 g daily.

Cephaloridine

Antibiotic

Synonym. Cefaloridine

Proprietary Names. Cephaloridin; Cepalorin; Ceporan; Ceporin(e); Keflodin; Loridine.

(7*R*)-3-(1-Pyridiniummethyl)-7-[2-(2-thienyl)acetamido]-3-cephem-4-carboxylate

$C_{19}H_{17}N_3O_4S_2 = 415.5$

CAS—50-59-9

A white crystalline powder, which discolours on exposure to light.

Soluble 1 in 5 of water and 1 in 1000 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 3.4.

Colour Tests. Mandelin's Test—violet; Marquis Test—red-violet.

Thin-layer Chromatography. System *TA*—Rf 73. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—241 nm ($A_1^1 = 350$ a), 254 nm ($A_1^1 = 341$ a); aqueous alkali—261 nm ($A_1^1 = 88$ b); methanol—234 nm ($A_1^1 = 372$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1600, 1764, 1656, 1538, 715, 1143 (KBr disk).

Dose. 1 to 3 g daily, intramuscularly; maximum of 6 g daily.

Cephalothin

Antibiotic

Synonym. Cefalotin

(7*R*)-3-Acetoxyethyl-7-[2-(2-thienyl)acetamido]-3-cephem-4-carboxylic acid

$C_{16}H_{16}N_2O_6S_2 = 396.4$

CAS—153-61-7

M.p. 160°.

Cephalothin Sodium

Proprietary Names. Ceporacin; Cepovenin; Keflin.

$C_{16}H_{15}N_2NaO_6S_2 = 418.4$

CAS—58-71-9

A white crystalline powder.

Soluble 1 in 3.5 of water and 1 in 700 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 2.2 (35°).

Ultraviolet Spectrum. Cephalothin sodium: water—237 nm ($A_1^1 = 335$ a), 265 nm ($A_1^1 = 204$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1704, 1724, 1637, 1600, 1227, 1510 (cephalothin sodium, KBr disk).

Dose. The equivalent of 4 to 12 g of cephalothin daily, intravenously.

Cephradine

Antibiotic

Synonym. Cefradine

Proprietary Names. Anspor; Eskacef; Maxisporin; Megacef; Sefril; Velosef.

(7*R*)-7-(α -D-Cyclohexa-1,4-dienylglycylamino)-3-methyl-3-cephem-4-carboxylic acid

$C_{16}H_{19}N_3O_4S = 349.4$

CAS—38821-53-3

A white to cream-coloured crystalline powder.

Soluble 1 in 100 of water and 1 in 70 of methanol; practically insoluble in ethanol, chloroform, and ether.

Dissociation Constant. pK_a 2.5, 7.3 (35°).

Ultraviolet Spectrum. Aqueous acid—257 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1754, 1582, 1678, 1271, 1235, 1190 (KBr disk).

Dose. 1 to 4 g daily.

Cetalkonium Chloride

Cationic Disinfectant

Proprietary Names. Baktonium. It is an ingredient of AAA, Bonjela, and Teejel.

Benzylhexadecyldimethylammonium chloride

$C_{25}H_{46}ClN = 396.1$

CAS—122-18-9

A white crystalline powder. M.p. 58° to 60°.

Sparingly **soluble** in cold water, soluble in hot water; soluble in ethanol, chloroform, and ether.

Thin-layer Chromatography. System TA—Rf 12, streaking. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—258 nm ($A_1^1 = 8$ b), 264 nm ($A_1^1 = 10$ b), 270 nm ($A_1^1 = 8$ b); methanol—253 nm, 258 nm, 263 nm ($A_1^1 = 11$ b), 270 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 722, 698, 1612, 1204, 875, 790 (KBr disk).

Use. In a concentration of 0.01% in preparations applied to the mouth or throat.

Cetrimide

Cationic Disinfectant

Proprietary Names. Cetavlon; Morpan CHSA; Silquat C100. It is an ingredient of Ceanel, Cetal (liquid), Savlocleans, Savlodil, Savlon (liquid), and Travasept.

Consists chiefly of tetradecyltrimethylammonium bromide together with smaller amounts of dodecyl- and hexadecyltrimethylammonium bromides.

CAS—8044-71-1

A white to creamy-white, voluminous, free-flowing, hygroscopic powder. A solution in water foams on shaking. M.p. 232° to 247°.

Soluble 1 in 2 of water; freely soluble in ethanol; soluble in ether.

Thin-layer Chromatography. *System TA*—Rf 02; *system TN*—Rf 100; *system TO*—Rf 50. (*Acidified iodoplatinate solution*, positive.)

Infra-red Spectrum. Principal peaks at wavenumbers 961, 909, 952, 719, 970, 724 (KCl disk).

Cetylpyridinium Chloride

Cationic Disinfectant

Proprietary Names. Ceepryn; Cepacol; Dobendan; Merocet(s). It is an ingredient of Merocaine and Tyrosolven.

1-Hexadecylpyridinium chloride monohydrate

$C_{21}H_{38}ClN \cdot H_2O = 358.0$

CAS—7773-52-6 (cetylpyridinium); 123-03-5 (chloride, anhydrous); 6004-24-6 (chloride, monohydrate)

A white powder. A solution in water foams strongly when shaken. M.p. 79° to 84°.

Soluble 1 in 20 of water; very soluble in ethanol and chloroform; slightly soluble in ether.

Thin-layer Chromatography. *System TA*—Rf 20. (*Acidified iodoplatinate solution*, positive.)

Ultraviolet Spectrum. Aqueous acid—260 nm ($A_1^1 = 123$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 685, 1629, 776, 1174, 715, 1205.

Use. In concentrations of 0.01 to 1%.

Chelidonium

Alkaloid

(+)-[5bS-(5b α ,6 β ,12b α)]-5b,6,7,12b,13,14-Hexahydro-13-methyl[1,3]benzodioxolo[5,6-c]-1,3-dioxolo[4,5-*i*]phenanthridin-6-ol

$C_{20}H_{19}NO_5 = 353.4$

CAS—476-32-4

An alkaloid obtained from the greater celandine, *Chelidonium majus* (Papaveraceae).

A white crystalline powder. M.p. 135° to 136°.

Practically **insoluble** in water; soluble in ethanol, chloroform, and ether.

Colour Tests. Mandelin's Test—yellow → green; Marquis Test—green; Sulphuric Acid—brown.

Thin-layer Chromatography. *System TA*—Rf 72. (*Acidified iodoplatinate solution*, positive.)

Infra-red Spectrum. Principal peaks at wavenumbers 1035, 1257, 1222, 1497, 748, 1070 (KBr disk).

Mass Spectrum. Principal peaks at m/z 332, 333, 304, 335, 176, 303, 334, 162.

Chlophedianol

Cough Suppressant

Synonym. Clofedanol

2-Chloro- α -(2-dimethylaminoethyl)- α -phenylbenzyl alcohol

$C_{17}H_{20}ClNO = 289.8$

CAS—791-35-5

**Chlophedianol Hydrochloride**

Proprietary Names. Detigon; Pectolitan.

$C_{17}H_{20}ClNO \cdot HCl = 326.3$

CAS—511-13-7

Crystals. M.p. 190° to 191°.

Soluble in water and ethanol; sparingly soluble in ether.

Colour Tests. Mandelin's Test—green-blue; Marquis Test—red-violet → brown.

Thin-layer Chromatography. *System TA*—Rf 52; *system TB*—Rf 41; *system TC*—Rf 37. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 2080.

Ultraviolet Spectrum. Aqueous acid—259 nm ($A_1^1 = 14.6$ a), 265 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 756, 700, 1035, 770, 1190, 735 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 254, 45, 44, 77, 42, 59, 72.

Dose. 75 to 100 mg of chlorthalidone hydrochloride daily.

Chloral Betaine

Hypnotic/Sedative

The adduct formed by chloral hydrate, $\text{CCl}_3 \cdot \text{CH}(\text{OH})_2$, and betaine, $\text{C}_5\text{H}_{11}\text{NO}_2$, containing about 58% of chloral hydrate.

$\text{C}_7\text{H}_{12}\text{Cl}_3\text{NO}_3 \cdot \text{H}_2\text{O} = 282.6$

CAS—2218-68-0

A white crystalline powder. M.p. about 124° , with decomposition.

Soluble 1 in 1 of water and 1 in 4 of ethanol; practically insoluble in chloroform and ether.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 840, 1630, 1085, 1130, 730, 1500 (KBr disk).

Mass Spectrum. Principal peaks at m/z 81, 83, 46, 110, 82, 112, 84, 117.

Dose. Usually 0.87 to 2.61 g daily, but doses of up to 3.5 g may be necessary.

Chloral Hydrate

Hypnotic/Sedative

Synonym. Chloral

Proprietary Names. Aquachloral; Chloradorm; Chloraldurat; Chloralex; Chloralvan; Dormel; Elix-Nocte; Noctec; Novochlorhydrate; Rectules.

2,2,2-Trichloroethane-1,1-diol

$\text{CCl}_3 \cdot \text{CH}(\text{OH})_2 = 165.4$

CAS—302-17-0

Colourless or white crystals which volatilise slowly on exposure to air and are decomposed by caustic alkalis, liberating chloroform. It liquefies between 50° and 58° and boils at 98° with dissociation into water and trichloroacetaldehyde.

Soluble 1 in 0.3 of water, 1 in 0.2 of ethanol, 1 in 3 of chloroform, and 1 in less than 1 of ether. Ethanolic solutions may deposit crystals of chloral ethanolate.

Dissociation Constant. pK_a 10.0.

Partition Coefficient. Log P (octanol), 0.6.

Colour Tests. Fujiwara Test—red; Palladium Chloride—black.

Gas Chromatography. *System GA*—RI 695 (tailing peak); *system GI*—retention time 12.5 min (tailing peak).

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 835, 1083, 1300, 970, 1620.

Mass Spectrum. Principal peaks at m/z 82, 47, 84, 29, 111, 83, 113, 85; trichloroacetic acid 44, 83, 85, 36, 28, —, —, —; trichloroethanol 31, 49, 77, 113, 115, 82, 51, 117.

Quantification. ULTRAVIOLET SPECTROPHOTOMETRY. In blood or urine: trichloroethanol (modified Fujiwara reaction)—A. J. McBay *et al.*, *J. analyt. Toxicol.*, 1980, 4, 99–101.

GAS CHROMATOGRAPHY. In plasma or urine: trichloroethanol, ECD—D. J. Berry, *J. Chromat.*, 1975, 107, 107–114. In blood or urine: chloral hydrate, trichloroethanol and trichloroacetic acid, head-space analysis, detection limit 500 ng/ml for chloral hydrate and trichloroethanol, ECD—D. D. Breimer *et al.*, *J. Chromat.*, 1974, 88, 55–63.

Disposition in the Body. Readily absorbed following oral administration. It is rapidly metabolised by reduction to trichloroethanol, the major active metabolite, which is further metabolised by conjugation with glucuronic acid to give urochlorallic acid and by oxidation to trichloroacetic acid, the major urinary metabolite. About 10 to 30% of a dose is excreted in the urine as urochlorallic acid and up to 5% as trichloroethanol in 24 hours. Trichloroacetic acid is slowly excreted in urine over several days; a small amount of urochlorallic acid may be excreted in the bile.

THERAPEUTIC CONCENTRATION. Chloral hydrate is difficult to detect in body fluids after normal doses. The plasma concentration of trichloroethanol is usually in the range 1.5 to 15 $\mu\text{g}/\text{ml}$. Trichloroacetic acid and urochlorallic acid are present in plasma at concentrations similar to, or greater than, those of trichloroethanol. When alcohol has been taken, peak plasma concentrations of trichloroethanol are increased and remain elevated for about 6 hours after ingestion, and those of trichloroacetic acid are decreased. Trichloroacetic acid accumulates in the plasma during chronic administration of chloral hydrate.

Following a single oral dose of 825 mg to 5 subjects, peak plasma-trichloroethanol concentrations of 7.6 to 12.2 $\mu\text{g}/\text{ml}$ (mean 9.7) were attained in 0.5 to 1 hour (D. J. Berry, *J. Chromat.*, 1975, 107, 107–114).

TOXICITY. Fatalities have occurred following the ingestion of 1.25 and 3 g but recovery has occurred after ingestion of 30 g. Plasma concentrations greater than 40 $\mu\text{g}/\text{ml}$ of trichloroethanol are likely to produce toxic effects; fatalities have been reported at blood concentrations of 20 to 155 to 495 $\mu\text{g}/\text{ml}$ of trichloroethanol.

In 4 fatalities known to involve the acute ingestion of 15 to 30 g of chloral hydrate, postmortem blood-trichloroethanol concentrations ranged from 100 to 640 $\mu\text{g}/\text{ml}$ (mean 265) (R. C. Baselt and R. H. Cravey, *J. analyt. Toxicol.*, 1977, 1, 81–103).

In a fatality due to the ingestion of chloral hydrate, the following postmortem tissue concentrations of trichloroethanol were reported: blood 55 $\mu\text{g}/\text{ml}$, brain 91 $\mu\text{g}/\text{g}$, liver 200 $\mu\text{g}/\text{g}$, urine 30 $\mu\text{g}/\text{ml}$ (A. Poklis *et al.*, *Bull. int. Ass. forens. Toxicol.*, 1973, 9(3 & 4), 8–9).

HALF-LIFE. Plasma half-life, chloral hydrate about 4 minutes, trichloroethanol about 8 hours, urochlorallic acid about 7 hours, trichloroacetic acid about 4 days.

VOLUME OF DISTRIBUTION. Trichloroethanol, about 0.6 litre/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, trichloroethanol, about 0.9.

PROTEIN BINDING. In plasma, trichloroethanol 35% and trichloroacetic acid 94%.

NOTE. For a review of the pharmacokinetics of hypnotic drugs see D. D. Breimer, *Clin. Pharmacokinet.*, 1977, 2, 93–109.

Dose. 0.5 to 2 g daily.

Chlorambucil

Antineoplastic

Synonym. Chlorbutinum

Proprietary Names. Chloraminophène; Leukeran.

4-[4-Bis(2-chloroethyl)aminophenyl]butyric acid

$C_{14}H_{19}Cl_2NO_2 = 304.2$

CAS—305-03-3

A white crystalline or granular powder. M.p. 64° to 69°. Practically **insoluble** in water; soluble 1 in 1.5 of ethanol, 1 in 2 of acetone, and 1 in 2.5 of chloroform; soluble in ether.

Caution. Chlorambucil is irritant; avoid contact with skin and mucous membranes.

Dissociation Constant. pK_a 5.8.

Partition Coefficient. Log P (octanol/pH 7.4), 1.7.

Thin-layer Chromatography. System TD—Rf 33; system TE—Rf 06; system TF—Rf 40.

Ultraviolet Spectrum. Methanol—258 nm ($A_1^1 = 642$ a), 303 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1695, 1520, 1229, 1610, 1175, 1270 (KBr disk).

Mass Spectrum. Principal peaks at m/z 254, 256, 118, 255, 303, 305, 63, 45.

Quantification. GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma: sensitivity <10 ng/ml—H. Ehrsson *et al.*, *J. pharm. Sci.*, 1980, 69, 710–712.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 100 ng/ml, UV detection—A. E. Ahmed *et al.*, *J. Chromat.*, 1982, 233; *Biomed. Appl.*, 22, 392–397.

Disposition in the Body. Rapidly absorbed after oral administration with peak plasma concentrations being attained in 0.5 to 2 hours. It is extensively metabolised; less than 1% of a dose is excreted in the urine unchanged. Phenylacetic acid mustard is a major metabolite.

HALF-LIFE. Plasma half-life, about 1 to 2 hours.

Dose. Initially 200 μg/kg daily, by mouth; maintenance, 30 to 100 μg/kg daily.

Chloramine

Disinfectant

Synonyms. Chloramidum; Chloramine T; Chloramina; Mianin; Natrium Sulfaminochloratum; Tosylchloramide Sodium.

Proprietary Names. Hydroclonazone; Klortee.

Note. The name Chloramin is applied to a preparation of chlorpheniramine maleate.

Sodium *N*-chlorotoluene-*p*-sulphonimidate trihydrate

$C_7H_7ClNNaO_2S \cdot 3H_2O = 281.7$

CAS—127-65-1 (anhydrous)

A white or slightly yellow crystalline powder. It effloresces in air, losing chlorine, becoming yellow in colour and less soluble in water.

Soluble 1 in 7 of water and 1 in 2 of boiling water; soluble 1 in 12 of ethanol, with slow decomposition; practically insoluble in chloroform and ether.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1165, 1316, 1105, 825, 710, 920 (KCl disk).

Use. As a 2% solution for wound irrigation.

Chloramphenicol

Antibiotic

Synonyms. Chloranfenicol; Cloranfenicol; Laevomycetinum.

Proprietary Names. Amphicol; Chloromycetin; Chloroptic; Econochlor; Fenicol; Kemictine; Novochlorocap; Sno Phenicol.

2,2-Dichloro-*N*-[(α , β)- β -hydroxy- α -hydroxymethyl-4-nitrophenethyl]acetamide

$C_{11}H_{12}Cl_2N_2O_5 = 323.1$

CAS—56-75-7

Fine, white to greyish-white or yellowish-white crystals. M.p. 149° to 153°. A solution in dehydrated alcohol is dextrorotatory and a solution in ethyl acetate is laevorotatory.

Soluble 1 in 400 of water and 1 in 2.5 of ethanol; freely soluble in acetone and ethyl acetate; slightly soluble in chloroform and ether.

Chloramphenicol Cinnamate

$C_{20}H_{18}Cl_2N_2O_6 = 453.3$

CAS—14399-14-5

A white or yellowish-white crystalline powder. M.p. about 119°.

Very slightly **soluble** in water; soluble 1 in 25 of ethanol, 1 in 50 of chloroform, and 1 in 500 of ether.

Chloramphenicol Palmitate

Synonyms. Chloramphenicol α -Palmitate; Palmitylchloramphenicol.

Proprietary Names. Chloromycetin Palmitate Suspension; Globenicol.

$C_{27}H_{42}Cl_2N_2O_6 = 561.5$

CAS—530-43-8

A fine, white, unctuous, crystalline powder. M.p. 87° to 95°.

Practically **insoluble** in water; soluble 1 in 45 of ethanol, 1 in 6 of chloroform, and 1 in 14 of ether; freely soluble in acetone; soluble in ethyl acetate.

Chloramphenicol Sodium Succinate

Synonym. Chloramphenicol α -Sodium Succinate

Proprietary Names. Chloromycetin Succinate; Globenicol; Kemictine Succinate; Mychel-S.

$C_{15}H_{15}Cl_2N_2NaO_8 = 445.2$

CAS—982-57-0

A white or yellowish-white hygroscopic powder.

Soluble 1 in less than 1 of water and 1 in 1 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 5.5.

Partition Coefficient. Log *P* (octanol), 1.1.

Colour Tests. Fujiwara Test—red; Nessler's Reagent—brown-orange.

Gas Chromatography. System GA—RI 2310.

Ultraviolet Spectrum. Water—278 nm ($A_1^1 = 298$ a). Chloramphenicol palmitate: dehydrated alcohol—271 nm ($A_1^1 = 178$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1681, 847, 1072, 1515, 816, 1562 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 70, 150, 151, 153, 77, 51, 118, 60.

Quantification. GAS CHROMATOGRAPHY. In cerebrospinal fluid, plasma or urine: ECD—L. K. Pickering *et al.*, *Clin. Chem.*, 1979, 25, 300–305. In urine: chloramphenicol or thiamphenicol and their metabolites, FID—T. Nakagawa *et al.*, *J. Chromat.*, 1975, 111, 355–364.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: chloramphenicol and chloramphenicol succinate, detection limits 500 ng/ml for chloramphenicol and 1 μ g/ml for the succinate, UV detection—R. Velagapudi *et al.*, *J. Chromat.*, 1982, 228; *Biomed. Appl.*, 17, 423–428. In cerebrospinal fluid, plasma or serum: sensitivity 100 to 200 ng/ml, UV detection—R. H. B. Sample *et al.*, *Antimicrob. Ag. Chemother.*, 1979, 15, 491–493.

Disposition in the Body. Readily absorbed after oral administration. The inactive palmitate ester is hydrolysed to free drug in the gastro-intestinal tract before absorption and the inactive sodium succinate ester, given parenterally, is similarly hydrolysed *in vivo*. It is widely distributed in the body, giving a concentration in the cerebrospinal fluid about 50% of that in the blood. The main metabolic pathway is conjugation with glucuronic acid; chloramphenicol is also hydrolysed to 1-(4-nitrophenyl)-2-aminopropane-1,3-diol. Both metabolites are inactive. Up to about 90% of a dose is excreted in the urine in 24 hours, mainly as the glucuronide, with about 5 to 10% of the dose in unchanged form. About 3% of the dose is excreted in the bile but this is mainly reabsorbed to give about 1% eliminated in the faeces.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 10 to 20 μ g/ml.

Following oral administration of chloramphenicol palmitate, equivalent to 15 to 27 mg/kg of chloramphenicol, four times a day to 18 children, plasma concentrations of 15.2 to 38.9 μ g/ml (mean 27.5) were reported 1.5 hours after a dose (R. E. Kauffman *et al.*, *J. Pediatr.*, 1981, 99, 963–967).

TOXICITY. There is an increased incidence of reversible bone marrow depression when plasma concentrations exceed 25 μ g/ml. The 'grey' syndrome (cardiovascular collapse, respiratory depression, and coma) has been reported in patients with plasma concentrations in the range 40 to 200 μ g/ml.

A 26-year-old woman received an initial 1-g dose followed in 7 and 12 hours by two 10-g doses. A plasma concentration of 201 µg/ml was measured 5½ hours after the last dose while she was in severe shock, but she recovered (W. L. Thompson *et al.*, *J. Am. med. Ass.*, 1975, 234, 149–150).

In a fatality involving ingestion of an unknown quantity of chloramphenicol (probably 2.5 to 4 g) by a 5-year-old boy, postmortem liver and urine concentrations of 10.7 µg/g and 2090 µg/ml, respectively, were reported; death occurred about 18 hours after ingestion (E. Grusz-Harday, *Bull. int. Ass. forens. Toxicol.*, 1973, 9(3 & 4), 10–11).

HALF-LIFE. Plasma half-life, about 2 to 5 hours.

VOLUME OF DISTRIBUTION. About 0.5 to 1 litre/kg.

CLEARANCE. Plasma clearance, about 4 ml/min/kg.

PROTEIN BINDING. In plasma, about 40 to 60%.

NOTE. For a review of the pharmacokinetics of chloramphenicol see P. J. Ambrose, *Clin. Pharmacokinet.*, 1984, 9, 222–238.

Dose. Usually 2 g daily.

Chlorbutol

Preservative

Synonyms. Acetone-Chloroforme; Alcohol Trichlorisobutylus; Chlorbutanol; Chlorbutanolum Hydratum; Chloretone; Chlorobutanol; Trichlorbutanolum.

1,1,1-Trichloro-2-methylpropan-2-ol hemihydrate

$C_4H_7Cl_3O \cdot \frac{1}{2}H_2O = 186.5$

CAS—57-15-8 (anhydrous); 6001-64-5 (hemihydrate)

Colourless or white crystals which are volatile at ordinary temperatures. M.p. about 76° to 79°; anhydrous chlorbutol, about 95°. B.p. about 167°.

Soluble 1 in 130 of water, 1 in 0.6 of ethanol, and 1 in 3 of chloroform; very soluble in ether.

Colour Test. Fujiwara Test—red.

Gas Chromatography. *System GA*—RI 949; *system GI*—retention time 29.8 min.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 790, 833, 1145, 1186, 917, 980 (Nujol mull).

Quantification. **GAS CHROMATOGRAPHY.** In blood, urine or tissues: limit of detection about 100 ng/ml, ECD—J. C. Valentour and I. Sunshine, *Z. Rechtsmed.*, 1975, 77, 61–63.

Disposition in the Body. Rapidly absorbed after oral administration, peak plasma concentrations being attained within 0.25 to 1 hour. About 10% of a dose is excreted in the urine in 17 days mostly as the glucuronide and sulphate conjugates.

TOXICITY.

In a non-fatal case of chlorbutol toxicity, a man who had been taking 1 to 1.5 g daily was admitted to hospital. An initial plasma concentration of about 100 µg/ml was reported and the plasma half-life was found to be about 13 days (T. Borody *et al.*, *Med. J. Aust.*, 1979, 1, 288).

In a fatality due to chlorbutol overdose, the following postmortem tissue concentrations were found: blood 64 µg/ml, bile 123 µg/ml, brain 161 µg/g, kidney 87 µg/g, liver 141 µg/g, spleen 120 µg/g, urine 31 µg/ml (J. C. Valentour and I. Sunshine, *Z. Rechtsmed.*, 1975, 77, 61–63).

HALF-LIFE. Plasma half-life, about 10 days.

VOLUME OF DISTRIBUTION. About 3 litres/kg.

PROTEIN BINDING. In plasma, about 50 to 60%.

NOTE. For a report on the pharmacokinetics of chlorbutol see C. Tung *et al.*, *Biopharm. Drug Disp.*, 1982, 3, 371–378.

Uses. Chlorbutol is used in a concentration of 0.5%. It was formerly given as a sedative in doses of 0.3 to 1.2 g.

Chlorcyclizine

Antihistamine

Synonym. Histachlorazine

(±)-1-(4-Chlorobenzhydryl)-4-methylpiperazine

$C_{18}H_{21}ClN_2 = 300.8$

CAS—82-93-9

A liquid.

Chlorcyclizine Hydrochloride

Synonym. Chlorcyclizinium Chloride

Proprietary Names. Di-Paralene; Trihistan. It is an ingredient of Fedrazil.

$C_{18}H_{21}ClN_2 \cdot HCl = 337.3$

CAS—1620-21-9; 14362-31-3

A white crystalline powder. M.p. about 225°.

Soluble 1 in 2 of water, 1 in 11 of ethanol, and 1 in 4 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 2.4, 7.8 (25°).

Colour Test. Liebermann's Test—red-orange.

Thin-layer Chromatography. *System TA*—Rf 57; *system TB*—Rf 42; *system TC*—Rf 46. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2225; *system GF*—RI 2560.

High Pressure Liquid Chromatography. *System HA*— k' 2.3.

Ultraviolet Spectrum. Aqueous acid—232 nm ($A_1^{1\%} = 581$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 988, 725, 760, 706, 1087, 870 (chlorcyclizine hydrochloride, Nujol mull).

Mass Spectrum. Principal peaks at m/z 99, 56, 72, 165, 300, 228, 229, 242.

Quantification. COLORIMETRY. In animal plasma or tissues: chlorcyclizine, cyclizine and their metabolites—R. Kuntzman *et al.*, *J. Pharmac. exp. Ther.*, 1965, 149, 29–35.

Disposition in the Body. Readily absorbed after oral administration and widely distributed throughout the body. Metabolised by *N*-demethylation to form norchlorcyclizine and by *N*-oxidation. High concentrations of the *N*-desmethyl metabolite are found in the liver, lungs, kidney, and spleen. Slowly excreted in the urine; measurable amounts of norchlorcyclizine have been detected in the urine for up to 3 weeks after the cessation of chronic oral administration. About 0.5% of a dose is excreted in the urine as the *N*-oxide.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 2 mg/kg to 4 subjects, average peak plasma concentrations of about 0.05 µg/ml and 0.03 µg/ml were attained in 5 hours for unchanged drug and norchlorcyclizine, respectively. After oral administration of 50 mg 3 times a day for 6 days, plasma concentrations of norchlorcyclizine of 0.05 to 0.11 µg/ml were reported on the first day after the cessation of treatment, and plasma concentrations of 0.02 to 0.04 µg/ml were found on the tenth day after cessation of treatment (R. Kuntzman *et al.*, *Ann. N.Y. Acad. Sci.*, 1973, 226, 131–147).

HALF-LIFE. Plasma half-life, chlorcyclizine about 12 hours, norchlorcyclizine 6 to 9 days.

PROTEIN BINDING. In plasma, norchlorcyclizine, about 85 to 90%.

Dose. 50 to 200 mg of chlorcyclizine hydrochloride daily.

Chlordane

Pesticide

Synonym. Chlordan

Proprietary Names. Murphy Ant Killer; Nippon Ant Powder; Sythane. It is an ingredient of Cooper Ant Killer.

1,2,4,5,6,7,8,8 - Octachloro - 2,3,3a,4,7,7a - hexahydro - 4,7 - methanoindene

$C_{10}H_6Cl_8 = 409.8$

CAS—57-47-9; 12789-03-6 (technical grade); 22212-52-8 (*cis*); 5103-74-2 (*trans*)

Technical chlordane is a mixture of chlorinated methanoindenes, the major components being the two stereoisomers *cis*-chlordane and *trans*-chlordane.

The technical grade is an amber viscous liquid which is decomposed by alkalis.

Practically **immiscible** with water, miscible with ethanol, chloroform, and ether.

Gas Chromatography. System GK—*cis*-chlordane and *trans*-chlordane retention times 1.08 and 1.06, respectively, relative to caffeine.

Infra-red Spectrum. Principal peaks at wavenumbers 704, 1265, 1020, 1075, 1612, 826.

Mass Spectrum. Principal peaks at *m/z* 373, 375, 377, 371, 44, 109, 75, 272 (*cis*-chlordane); 373, 375, 377, 371, 272, 237, 75, 65 (*trans*-chlordane).

Quantification. GAS CHROMATOGRAPHY. In blood—W. E. Dale *et al.*, *Life Sci.*, 1966, 5, 46–54.

Disposition in the Body. Readily absorbed from the gastrointestinal tract, lungs, and the skin. It is stored in adipose tissue. Oxychlordane has been detected in adipose tissue and breast milk.

TOXICITY. Severe toxicity may result after ingestion or skin contamination with greater than 1 g, and fatalities have occurred after the ingestion of more than 2 g and after excessive skin contamination. The maximum permissible atmospheric concentration is 0.5 mg/m³.

In a non-fatal poisoning case, a 4-year-old child who ingested an unknown amount of chlordane and developed intermittent convulsions had an initial serum concentration of 3.4 µg/ml which decreased to 0.14 µg/ml after 72 hours; the rate of decline of the serum concentration was non-linear with a terminal half-life of 88 days. Urine samples obtained during the first 3 days after ingestion, showed a decrease from 1.9 µg/ml to 0.05 µg/ml but increased to 0.13 µg/ml on the 35th day (F. D. Aldrich and J. M. Holmes, *Archs envir. Hlth*, 1969, 19, 129–132).

The following postmortem concentrations were reported in a fatality due to the ingestion of chlordane: blood 4.4 µg/ml, urine 0.24 µg/ml (R. O. Bost and I. Sunshine, *Bull. int. Ass. forens. Toxicol.*, 1978, 14(1), 30).

A 66-year-old man who ingested about 400 ml of a 70% commercial solution and died after 40 hours had the following postmortem tissue concentrations: blood 1.7 µg/ml, fat 378 µg/g, kidney 14 µg/g, liver 43 µg/g, urine 0.6 µg/ml (R. Morano per *Disposition of Toxic Drugs and Chemicals in Man*, 2nd Edn, R. C. Baselt (Ed.), Davis, California, Biomedical Publications, 1982, pp. 140–142).

Chlordantoin*Synonym.* Clodantoin*Proprietary Name.* Sporostacin

5-(1-Ethylpentyl)-3-(trichloromethylthio)imidazolidine-2,4-dione

 $C_{11}H_{17}Cl_3N_2O_2S = 347.7$

CAS—5588-20-5

**Ultraviolet Spectrum.** No significant absorption, 230 to 360 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1730, 1786, 730, 1059, 766, 1309.**Use.** Topically in a concentration of 1%.**Chlordiazepoxide***Tranquilliser**Synonym.* Methaminodiazepoxide*Proprietary Names.* Libritabs; Librium (tablets); Risolid. It is an ingredient of Libraxin, Limbatril, Limbitrol, and Menrium.

7-Chloro-2-methylamino-5-phenyl-3H-1,4-benzodiazepine 4-oxide

 $C_{16}H_{14}ClN_3O = 299.8$

CAS—58-25-3

A yellow crystalline powder, sensitive to sunlight. M.p. about 240°.

Practically **insoluble** in water; soluble 1 in 50 of ethanol and 1 in 130 of ether; slightly soluble in chloroform.**Chlordiazepoxide Hydrochloride***Proprietary Names.* A-Poxide; Corax; C-Tran; Librium; Medilium; Nack; Novopoxide; Relaxil; SK-Lygen; Solium; Trilium; Tropium. It is an ingredient of Librax. $C_{16}H_{14}ClN_3O \cdot HCl = 336.2$

CAS—438-41-5

A white or slightly yellowish crystalline powder. M.p. 212° to 218°, with decomposition.

Soluble 1 in 10 of water and 1 in 40 of ethanol; practically insoluble in chloroform and ether.**Dissociation Constant.** pK_a 4.6 (20°).**Partition Coefficient.** Log *P* (octanol/pH 7.4), 2.5.**Colour Test.** Marquis Test—yellow.**Thin-layer Chromatography.** *System TA*—Rf 62; *system TB*—Rf 02; *system TC*—Rf 50; *system TD*—Rf 10; *system TE*—Rf 51; *system TF*—Rf 11. (*Dragendorff spray*, positive; *FPN reagent*, yellow; *acidified iodoplatinate solution*, positive; *Marquis reagent*, yellow.)**Gas Chromatography.** *System GA*—chlordiazepoxide RI 2453, 2530, 2799, demoxepam RI 2529, desmethyldiazepam RI 2496, oxazepam RI 2336; *system GG*—chlordiazepoxide RI 3065, desmethyldiazepam RI 3041, oxazepam RI 2803.**High Pressure Liquid Chromatography.** *System HI*—chlordiazepoxide k' 6.41, demoxepam k' 2.42, desmethylchlordiazepoxide k' 4.47, desmethyldiazepam k' 8.00, oxazepam k' 4.62; *system HK*—chlordiazepoxide k' 2.87, demoxepam k' 0.03, desmethylchlordiazepoxide k' 2.39, desmethyldiazepam k' 1.99, oxazepam k' 0.73.**Ultraviolet Spectrum.** Aqueous acid—246 nm (A_1^{1112} a), 308 nm; aqueous alkali—262 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1625, 760, 1260, 690, 1590, 850 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 282, 299, 284, 283, 241, 56, 301, 253; demoxepam 285, 286, 269, 287, 241, 242, 77, 270; desmethylchlordiazepoxide 285, 268, 284, 77, 286, 42, 287, 233; desmethyldiazepam 242, 269, 270, 241, 243, 271, 244, 272; oxazepam 257, 77, 268, 239, 205, 267, 233, 259.**Quantification.** GAS CHROMATOGRAPHY. In serum: chlordiazepoxide and demoxepam, sensitivity 45 ng/ml for chlordiazepoxide, ECD—S. R. Sun and D. J. Hoffman, *J. pharm. Sci.*, 1978, 67, 1647–1648.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: chlordiazepoxide and four metabolites, detection limit 20 ng/ml for all compounds, UV detection—T. B. Vree *et al.*, *J. Chromat.*, 1981, 224; *Biomed. Appl.*, 13, 519–525.

RADIOIMMUNOASSAY. In blood, plasma or saliva: sensitivity 50 ng/ml in blood or plasma and 500 pg/ml in saliva—R. Dixon *et al.*, *J. pharm. Sci.*, 1979, 68, 261.

Disposition in the Body. Readily absorbed after oral administration; bioavailability almost 100%. Metabolised by demethylation and subsequent deamination to the active metabolites desmethylchlordiazepoxide and demoxepam. Demoxepam is further metabolised by hydrolysis with cleavage of the lactam ring and by reduction to desmethylchlorazepam (nordazepam) followed by hydroxylation to oxazepam (desmethylchlorazepam and oxazepam are also pharmacologically active). About 60% of a dose is excreted in the urine and 10 to 20% is eliminated in the faeces; less than 1% of a dose is excreted in the urine unchanged, about 6% is excreted as demoxepam, and the remainder as ring-opened derivatives and glucuronide conjugates of oxazepam and other hydroxylated metabolites.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.4 to 4 µg/ml. Demoxepam and desmethylchlorazepam may accumulate in the plasma of patients on chronic therapy; demoxepam is not normally detectable in plasma after a single dose of chlordiazepoxide.

Following a single oral dose of 20 mg to 6 subjects, peak plasma concentrations of 0.78 to 1.24 µg/ml (mean 1.0) of chlordiazepoxide were attained in 2 to 6 hours; desmethylchlordiazepoxide was detectable 5 hours after the dose and peak plasma concentrations of 0.14 to 0.46 µg/ml (mean 0.3) were attained in 8 to 24 hours (M. A. Schwartz *et al.*, *J. pharm. Sci.*, 1971, 60, 1500–1503).

Following daily oral administration of 10 mg three times a day to 8 subjects, mean steady-state plasma concentrations were: chlordiazepoxide 0.5 to 1.0 µg/ml (mean 0.8), desmethylchlordiazepoxide 0.3 to 0.8 µg/ml (mean 0.5), demoxepam 0.24 to 0.44 µg/ml (mean 0.36) (H. G. Boxenbaum *et al.*, *J. Pharmacokinetic. Biopharm.*, 1977, 5, 25–39).

TOXICITY. Toxic reactions may be produced by plasma concentrations greater than 3 µg/ml; plasma concentrations in the region of 20 µg/ml may produce coma or death, but fatalities caused by chlordiazepoxide alone are rare. Recoveries have occurred after the ingestion of single doses of about 2 g.

The following postmortem chlordiazepoxide tissue concentrations were reported in a fatality in which death occurred 18 to 20 hours after the ingestion of an unknown quantity of chlordiazepoxide: blood 26.4 µg/ml, bile 39 µg/ml, kidney 11 µg/g, liver 10 µg/g, spleen 9 µg/g, urine 7.8 µg/ml (H. Mohseni, *Bull. int. Ass. forens. Toxicol.*, 1975, 11(2), 17–18).

The following peak plasma concentrations were observed in a comatose adult subject who had ingested 1 g: chlordiazepoxide 20 µg/ml after 6 hours, desmethylchlordiazepoxide 12 µg/ml after 21 hours, demoxepam 9 µg/ml after 51 hours (J. A. F. de Silva and L. D'Arconte, *J. forens. Sci.*, 1969, 14, 184–202).

HALF-LIFE. Plasma half-life, chlordiazepoxide 5 to 30 hours (mean 15), demoxepam 14 to 95 hours (mean 40); desmethylchlorazepam about 40 to 100 hours, but there is considerable intersubject variation—see under Nordazepam.

VOLUME OF DISTRIBUTION. 0.3 to 0.6 litre/kg.

CLEARANCE. Plasma clearance, about 0.5 ml/min/kg.

SALIVA. Plasma: saliva ratio, about 33.

PROTEIN BINDING. In plasma, about 90 to 97%.

NOTE. For a review of the pharmacokinetics of chlordiazepoxide see D. J. Greenblatt *et al.*, *Clin. Pharmacokinetic.*, 1978, 3, 381–394.

Dose. 30 to 100 mg daily.

Chlorhexidine

Cationic Disinfectant

Proprietary Names. Hexol. It is an ingredient of Cetol (liquid).

1,1'-Hexamethylenebis[5-(4-chlorophenyl)biguanide]

$C_{22}H_{30}Cl_2N_{10}$ = 505.5

CAS—55-56-1

Crystals. M.p. 134°.

Chlorhexidine Acetate

Proprietary Names. Hibitane (powder). It is an ingredient of Norgotin and Travasept.

$C_{22}H_{30}Cl_2N_{10} \cdot 2C_2H_4O_2$ = 625.6

CAS—56-95-1

A white to pale cream microcrystalline powder. When heated it decomposes with the production of trace amounts of 4-chloroaniline. Aqueous solutions slowly decompose.

Soluble 1 in 55 of water and 1 in 15 of ethanol; very slightly soluble in propylene glycol.

Chlorhexidine Gluconate Solution

Proprietary Names. Corsodyl; Dispray; Hibicare; Hibiclens; Hibidil; Hibiscrub; Hibisol; Hibitane (solution); pHiso-MED; Rotersept. It is an ingredient of Cyteal, Eludril, Savlocens, Savlodil, Savlon (liquid) and Stomosal.

An aqueous solution containing 19 to 21% of $C_{22}H_{30}Cl_2N_{10} \cdot 2C_6H_{12}O_7$ (= 897.8).

CAS—18472-51-0 (chlorhexidine gluconate)

A colourless to pale straw-coloured liquid which is affected by light. Wt per ml 1.06 to 1.07 g.

Miscible with water, with up to 5 parts of ethanol, and with up to 3 parts of acetone.

Chlorhexidine Hydrochloride

Proprietary Names. Hibitane (powder); Sterilon (powder).

$C_{22}H_{30}Cl_2N_{10} \cdot 2HCl$ = 578.4

CAS—3697-42-5

A white crystalline powder, affected by light. M.p. about 255°, with decomposition.

Soluble 1 in 1700 of water, 1 in 450 of ethanol, and 1 in 50 of propylene glycol; slightly soluble in methanol.

Colour Test. Stir a small quantity on a white tile with a drop of bromine solution followed by a drop of sodium hydroxide solution—red.

Thin-layer Chromatography. System TA—Rf 33. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—245 nm; aqueous alkali (pH 10)—232 nm, 253 nm. (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1527, 1628, 1575, 1235, 820, 1080 (KBr disk). (See below)

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In blood, serum or urine: sensitivity 1 µg/ml, UV detection—C. E. Huston *et al.*, *J. Chromat.*, 1982, 237, 457–464.

Use. Chlorhexidine gluconate is used in solutions containing 0.01 to 0.5%.

**Chlormadinone Acetate***Progestational Steroid**Proprietary Names.* Gestafortin; Lutéran.6-Chloro-3,20-dioxopregna-4,6-dien-17 α -yl acetate $C_{23}H_{29}ClO_4 = 404.9$

CAS—1961-77-9 (chlormadinone); 302-22-7 (acetate)

A white to creamy-white, fluffy, crystalline powder. M.p. 208° to 212°.

Practically **insoluble** in water; soluble 1 in 160 of ethanol, 1 in 1.5 of chloroform, and 1 in 210 of ether.

Ultraviolet Spectrum. Methanol—285 nm ($A_1^1 = 575$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1238, 1724, 1646, 1219, 881, 1597 (KBr disk).

Dose. Chlormadinone acetate has been given in doses of 2 to 10 mg daily.

Chlormethiazole*Hypnotic/Sedative**Synonym.* Clomethiazole*Proprietary Names of Chlormethiazole and Chlormethiazole Edisylate.* Distraneurin(e); Hemineurin(e); Heminevrin.

5-(2-Chloroethyl)-4-methylthiazole

 $C_6H_8ClNS = 161.6$

CAS—533-45-9

A colourless to slightly yellow-brown, oily, viscous liquid.

Soluble 1 in 100 of water; miscible with ethanol, chloroform, and ether.

Chlormethiazole Edisylate*Synonym.* Chlormethiazole Ethanedisulphonate $C_{14}H_{22}Cl_2N_2O_6S_4 = 513.5$

CAS—1867-58-9

A white crystalline powder. M.p. 126° to 129°.

Freely **soluble** in water and warm ethanol; practically insoluble in ether.**Dissociation Constant.** pK_a 3.2.**Colour Test.** Sodium Nitroprusside (Method 3)—violet.

Thin-layer Chromatography. *System TA*—Rf 64; *system TB*—Rf 44; *system TC*—Rf 69. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1230.**High Pressure Liquid Chromatography.** *System HA*— k' 0.1.

Ultraviolet Spectrum. Aqueous acid—258 nm ($A_1^1 = 288$ a); aqueous alkali—250 nm ($A_1^1 = 270$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1190, 1227, 1041, 1031, 779, 823 (chlormethiazole edisylate, KBr disk).

Mass Spectrum. Principal peaks at m/z 112, 161, 85, 45, 163, 113, 114, 59.

Quantification. GAS CHROMATOGRAPHY. In blood or plasma: chlormethiazole and two metabolites, sensitivity 32 ng for chlormethiazole in plasma, AFID—S. E. Tsuei *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 55–62. In plasma or urine: sensitivity 50 ng/ml for chlormethiazole edisylate, FID—R. G. Moore *et al.*, *Eur. J. clin. Pharmac.*, 1975, 8, 353–357.

GAS CHROMATOGRAPHY-MASS SPECTROMETRY. In blood or plasma: sensitivity 1 ng/ml—K. G. Jostell *et al.*, *Acta pharmac. tox.*, 1978, 43, 180–189. In plasma: chlormethiazole and two metabolites, sensitivity 1 ng/ml for chlormethiazole—R. L. Nation *et al.*, *Eur. J. clin. Pharmac.*, 1977, 12, 137–145.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit 200 ng/ml, UV detection—R. Hartley *et al.*, *J. Chromat.*, 1983, 276; *Biomed. Appl.*, 27, 471–477.

Disposition in the Body. Rapidly absorbed after oral administration but extensively metabolised. A considerable number of metabolites have been identified in small quantities in urine. Less than 5% of a dose is excreted unchanged in the urine, and up to about 14% is excreted as 4-methylthiazole-5-acetic acid. Other metabolites identified in the urine include 5-(1-hydroxy-2-chloroethyl)-4-methylthiazole and 5-(2-hydroxyethyl)thiazole-4-carbolactone (which appear to be more abundant than 4-methylthiazole-5-acetic acid), together with 5-acetyl-4-methylthiazole, 5-(1-hydroxyethyl)-4-methylthiazole, and 5-(2-hydroxyethyl)-4-methylthiazole in both free and conjugated forms. 5-Ethyl-2-hydroxy-4-methylthiazole has been found in the tissues following overdoses of chlormethiazole. 5-(1-Hydroxyethyl)-4-methylthiazole and 5-acetyl-4-methylthiazole may be present in the plasma at concentrations similar to, or greater than those of unchanged drug.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.1 to 2.8 µg/ml.

Following single oral doses of 192 mg to 6 subjects, peak plasma concentrations of 0.10 to 0.55 µg/ml (mean 0.27) were attained in about 0.6 hour (P. J. Pentikainen *et al.*, *Eur. J. clin. Pharmac.*, 1980, 17, 275–284).

TOXICITY. Toxic effects are associated with plasma concentrations of 1.6 to 13 to 26 µg/ml, and fatalities with concentrations of 8 to 50 to 170 µg/ml.

In a report of 9 cases of fatal overdose, in which doses of about 10 to 50 g had been ingested, postmortem blood concentrations of 25 to 80 µg/ml (mean 56) were found; in a further 6 fatalities due to chlormethiazole and alcohol ingestion, postmortem blood concentrations ranged from 5 to 47 µg/ml (mean 21) (S. Jakobsson and M. Möller, *Forens. Sci.*, 1972, 1, 114).

In a report of 2 cases of fatal overdose, postmortem concentrations were: blood 21 and 214 µg/ml, liver blood 21 and 100 µg/ml, bile 38 and 143 µg/ml, urine 5 and 114 µg/ml; in three further cases blood concentrations were reported to be 3.4, 50, and 75 µg/ml (A. E. Robinson and R. D. McDowall, *Forens. Sci. Int.*, 1979, 14, 49–55).

HALF-LIFE. Plasma half-life, about 3 to 7 hours, increased in elderly subjects and in patients with liver disease.

VOLUME OF DISTRIBUTION. About 3 to 12 litres/kg (mean 8).

CLEARANCE. Plasma clearance, 10 to 25 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 1.2.

PROTEIN BINDING. In plasma, about 60 to 70%.

NOTE. For a review of chlormethiazole toxicity see A. Houston *et al.*, *Human Toxicol.*, 1983, 2, 361–369.

Dose. Chlormethiazole as Heminevrin (*Astra*) is given in doses of 2 to 3 capsules daily. An initial dose of 12 capsules daily, for 2 days, is given in alcohol withdrawal.

NOTE. Due to variations in bioavailability: for an equivalent therapeutic effect, one capsule (192 mg chlormethiazole base) ≡ 5 ml syrup (250 mg/5 ml chlormethiazole edisylate).

Chlormezanone

Tranquilliser

Synonym. Chlormethazanone

Proprietary Names. Rexan; Rilauquil; Supotran; Tanafol; Tran-copal. It is an ingredient of Lobak and Trancoprin.

2-(4-Chlorophenyl)-3-methylperhydro-1,3-thiazin-4-one 1,1-dioxide

$C_{11}H_{12}ClNO_3S = 273.7$

CAS—80-77-3

A white crystalline powder. M.p. about 115°.

Very slightly **soluble** in water; sparingly soluble in ethanol; freely soluble in acetone and chloroform.

Thin-layer Chromatography. *System TA*—Rf 66; *system TB*—Rf 01; *system TC*—Rf 63.

Gas Chromatography. *System GA*—RI 2238.

Ultraviolet Spectrum. Aqueous acid—258 nm, 265 nm ($A_1^1 = 23$ b), 272 nm; aqueous alkali—259 nm. (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1650, 1150, 1130, 1315, 880, 1090 (KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 98, 152, 154, 42, 69, 174, 208, 153.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 100 ng/ml, ECD—K. Ohya *et al.*, *J. Chromat.*, 1980, 221; *Biomed. Appl.*, 10, 67–74.

Disposition in the Body. Rapidly absorbed after oral administration. Less than 5% of a dose is excreted in the urine as unchanged drug in 48 hours; about 40% of a dose is excreted in the urine in 72 hours as acidic metabolites, mainly 4-chlorohippuric acid.

**THERAPEUTIC CONCENTRATION.**

After a single oral dose of 200 mg to 5 subjects, peak plasma concentrations of 2.5 to 3.4 µg/ml (mean 2.8) were attained in about 4 hours (K. Ohya *et al.*, *ibid.*).

After a single oral dose of 400 mg to 4 subjects, peak plasma concentrations of 4.9 to 9.9 µg/ml (mean 7) were attained in 1 to 2 hours; following oral doses of 150 mg three times a day for 3 days to 4 subjects, plasma concentrations of 5.8 to 8.4 µg/ml (mean 6.8) were reported 2 hours after the final dose (E. W. McChesney *et al.*, *Biochem. Pharmacol.*, 1967, 16, 813–826).

TOXICITY.

In a fatality due to the combined ingestion of chlormezanone (possibly up to 10 g) and diazepam, the following postmortem tissue concentrations of chlormezanone were reported: blood 53 µg/ml, brain 109 µg/g, liver 88 µg/g, urine 31 µg/ml (J. Kristinsson, *Bull. int. Ass. forens. Toxicol.*, 1980, 15(2), 6–7).

A 36-year-old woman was admitted to hospital comatose following the ingestion of 7 g of chlormezanone; an initial plasma concentration of 60 µg/ml was reported which declined with a half-life of 29 hours; the patient regained consciousness after 15 hours (D. Armstrong *et al.*, *Br. med. J.*, 1983, 286, 845–846).

HALF-LIFE. Plasma half-life, about 20 to 30 hours.

PROTEIN BINDING. In plasma, about 50%.

Dose. 300 to 800 mg daily.

Chlorocresol

Disinfectant

Synonyms. Chlorkresolum; Parachlorometacresol; PCMC.

Proprietary Name. Wright's Vaporizing Fluid

4-Chloro-3-methylphenol

C₇H₇ClO = 142.6

CAS—59-50-7

Colourless crystals or crystalline powder. It is volatile in steam. M.p. 64° to 66°.

Soluble 1 in 260 of water, 1 in 50 of boiling water, and 1 in 0.4 of ethanol; soluble in acetone, chloroform, and ether. Solutions in water acquire a yellowish colour on exposure to light and air.

Dissociation Constant. pK_a 9.2 (20°).

Ultraviolet Spectrum. Aqueous acid—279 nm (A₁¹ = 105 a); aqueous alkali—244 nm, 299 nm.

Use. In concentrations of 0.1 to 0.2%.

Chloroform

General Anaesthetic

Synonyms. Chloroformium Anaestheticum; Chloroformum pro Narcosi.

Trichloromethane

CHCl₃ = 119.4

CAS—67-66-3

A colourless mobile volatile liquid. Wt per ml 1.474 to 1.479 g. B.p. about 61°. Refractive index 1.4464.

Chloroform (B.P.) contains 1 to 2% v/v of ethanol.

Soluble 1 in 200 of water; miscible with dehydrated alcohol and ether.

Colour Tests. Fujiwara Test—red; Palladium Chloride—black. Heat with a small amount of resorcinol in 2M sodium hydroxide—red. If the resorcinol is replaced by either alpha- or betanaphthol—blue.

Gas Chromatography. System GA—RI 605; system GI—retention time 6.2 min.

Infra-red Spectrum. Principal peaks at wavenumbers 714, 787, 1205, 1220, 928, 1515 (thin film).

Mass Spectrum. Principal peaks at m/z 83, 85, 47, 87, 48, 49, 35, 82.

Quantification. GAS CHROMATOGRAPHY. In blood: FID—N. Poobalasingham, *Br. J. Anaesth.*, 1976, 48, 953–956. In expired air, blood or urine: ECD—B. J. Fry *et al.*, *Archs int. Pharmacodyn. Ther.*, 1972, 196, 98–111.

Disposition in the Body. Almost completely absorbed after oral administration, rapidly absorbed after inhalation and subject to first-pass metabolism in the liver and lungs. It is rapidly distributed throughout the body and is taken up by adipose tissue. Between 20 and 70% of a dose is exhaled unchanged in 8 hours and up to about 50% is exhaled as carbon dioxide in the same period; less than 0.01% of a dose is excreted in the urine.

BLOOD CONCENTRATION.

After a single oral dose of 500 mg to 2 subjects, peak blood concentrations of about 1 and 5 µg/ml were attained in 1 hour (B. J. Fry *et al.*, *Archs. int. Pharmacodyn. Ther.*, 1972, 196, 98–111).

A mean chloroform concentration in arterial blood of 173 µg/ml was reported in spontaneously breathing subjects during surgical anaesthesia (N. Poobalasingham and J. P. Payne, *Br. J. Anaesth.*, 1978, 50, 325–329).

TOXICITY. The minimum lethal dose is 10 ml by ingestion and the maximum permissible atmospheric concentration is 10 ppm. Exposure to air concentrations of 100 to 1000 ppm for short periods may cause discomfort and dizziness and concentrations of 7000 ppm or more will produce rapid loss of consciousness.

The following postmortem tissue concentrations were reported in 7 fatalities: blood 10 to 48 µg/ml (mean 32, 7 cases); brain 50.4 to 156 µg/g (mean 101, 4 cases); kidney 16 to 27 µg/g (mean 20, 3 cases); liver 6 to 86.2 µg/g (mean 43.4, 6 cases); urine 0 to 60 µg/ml (mean 15, 5 cases) (R. Bonnicksen and A. C. Maehly, *J. forens. Sci.*, 1966, 11, 414–427 and G. V. Giusti and M. Chiarotti, *Medicine, Sci. Law*, 1981, 21, 2–3).

HALF-LIFE. Blood half-life, about 1.5 hours.

VOLUME OF DISTRIBUTION. In blood, about 2 to 3 litres/kg.

CLEARANCE. Blood clearance, about 20 ml/min/kg.

Dose. Concentrations of 2 to 4% of the vapour have been used for induction and 1 to 2% for maintenance of anaesthesia.

Chloroprocaine

Local Anaesthetic

2-Diethylaminoethyl 4-amino-2-chlorobenzoate

$C_{13}H_{19}ClN_2O_2 = 270.8$

CAS—133-16-4

Chloroprocaine Hydrochloride

Proprietary Name. Nesacaine

$C_{13}H_{19}ClN_2O_2 \cdot HCl = 307.2$

CAS—3858-89-7

A white crystalline powder. M.p. 173° to 176°.

Soluble 1 in 20 of water and 1 in 100 of ethanol; very slightly soluble in chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 8.7.

Colour Test. Diazotisation—red.

Thin-layer Chromatography. System TA—Rf 59; system TB—Rf 05; system TC—Rf 23; system TL—Rf 37. (Acidified iodoplatinate solution, positive; Van Urk reagent, yellow.)

Gas Chromatography. System GA—RI 2229.

High Pressure Liquid Chromatography. System HQ— k' 0.24.

Ultraviolet Spectrum. Aqueous acid—230 nm ($A_1^1 = 330$ b), 288 nm ($A_1^1 = 311$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1595, 1698, 1240, 1625, 1111, 1315 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 99, 154, 30, 87, 58, 29, 156.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, FID—J. E. O'Brien *et al.*, *J. pharm. Sci.*, 1979, 68, 75–78.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma: sensitivity < 2 ng/ml—B. R. Kuhnert *et al.*, *J. Chromat.*, 1981, 224; *Biomed. Appl.*, 13, 488–491.

THIN-LAYER CHROMATOGRAPHY. In plasma, whole blood or urine: 4-amino-2-chlorobenzoic acid—J. E. O'Brien *et al.*, *J. pharm. Sci.*, 1979, 68, 75–78.

Disposition in the Body. Rapidly hydrolysed in the plasma to 4-amino-2-chlorobenzoic acid and 2-diethylaminoethanol. About 50% of an intravenous dose is excreted in the urine in 90 minutes, mainly as an unidentified conjugate (possibly the glycine conjugate) of 4-amino-2-chlorobenzoic acid.

THERAPEUTIC CONCENTRATION.

After intravenous infusion of 250 mg over a period of 30 minutes to 3 subjects, peak plasma concentrations of 3.5 to 4.3 µg/ml of 4-amino-2-chlorobenzoic acid were attained at the end of the infusion; chlorprocaine was not detectable in the plasma (J. E. O'Brien *et al.*, *ibid.*).

Toxicity. The maximum safe intravenous or topical dose is 750 mg.

Dose. Chlorprocaine hydrochloride is injected as a 0.5 to 3% solution.

Chloropyrilene

Antihistamine

Synonyms. Chloromethapyrilene; Chlorothen; Chloropyrilene; Histachlorylene.

N - (5 - Chloro - 2 - thenyl) - *N'* *N'* - dimethyl - *N* - (2 - pyridyl) - ethylenediamine

$C_{14}H_{18}ClN_3S = 295.8$

CAS—148-65-2

A liquid.

Chloropyrilene Citrate

Proprietary Name. Panta

$C_{14}H_{18}ClN_3S \cdot C_6H_8O_7 = 488.0$

CAS—148-64-1

A white crystalline powder. M.p. 112° to 116°; on further heating it gradually solidifies and remelts at 125° to 140°, with decomposition.

Soluble 1 in 35 of water; sparingly soluble in ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 8.4 (25°).

Colour Tests. Mandelin's Test—violet → orange; Marquis Test—violet.

Thin-layer Chromatography. System TA—Rf 53. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2133.

High Pressure Liquid Chromatography. System HA— k' 4.0.

Ultraviolet Spectrum. Aqueous acid—237 nm ($A_1^1 = 520$ c), 312 nm; aqueous alkali—243 nm ($A_1^1 = 676$ b), 308 nm ($A_1^1 = 148$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1595, 767, 990, 1562, 1149, 1234 (KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 131, 72, 71, 79, 42, 30, 78.

Dose. Up to 150 mg of chloropyrilene citrate daily.

Chloroquine

Antimalarial

Synonym. Cloroquina

7-Chloro-4-(4-diethylamino-1-methylbutylamino)quinoline

$C_{18}H_{26}ClN_3 = 319.9$

CAS—54-05-7

A white or slightly yellow crystalline powder. M.p. 87° to 92°. Very slightly **soluble** in water; soluble in chloroform and ether.

Chloroquine Phosphate

Synonyms. Chingaminum; Chlorochinum Diphosphoricum; Quingamine.

Proprietary Names. Aralen (tablets); Avlocor; Chlorquin; Klorokin; Malarivon; Resochin(e). It is an ingredient of Aralis.

$C_{18}H_{26}ClN_3 \cdot 2H_3PO_4 = 515.9$

CAS—50-63-5

A white powder. It discolours on exposure to light. There are 2 forms which melt at 193° to 195° and at 210° to 215°.

Soluble 1 in 4 of water; very slightly soluble in ethanol; practically insoluble in chloroform and ether.

Chloroquine Sulphate

Proprietary Name. Nivaquine

$C_{18}H_{26}ClN_3 \cdot H_2SO_4 \cdot H_2O = 436.0$

CAS—132-73-0 (anhydrous)

A white crystalline powder. M.p. 205° to 210°.

Soluble 1 in 3 of water; practically insoluble in ethanol and acetone; very sparingly soluble in chloroform and ether.

Dissociation Constant. pK_a 8.4, 10.8 (20°).

Colour Test. Liebermann's Test (100°)—orange.

Thin-layer Chromatography. System TA—Rf 38; system TB—Rf 14; system TC—Rf 04. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2590; system GF—RI 3245.

High Pressure Liquid Chromatography. System HA— k' 15.2 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—257 nm, 329 nm ($A_1^1 = 600$ b), 343 nm ($A_1^1 = 625$ b); aqueous alkali—254 nm ($A_1^1 = 555$ b), 330 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1573, 1538, 1612, 1155, 800, 870 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 58, 319, 87, 73, 247, 245, 112.

Quantification. SPECTROFLUORIMETRY. In plasma, erythrocytes or urine: sensitivity 5 ng/ml—S. A. Adelusi and L. A. Salako, *J. Pharm. Pharmac.*, 1980, 32, 711–712.

GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In plasma or blood: sensitivity 3 ng/ml for chloroquine and monodesethyl-

chloroquine, 10 ng/ml for didesethylchloroquine, AFID—Y. Bergqvist and S. Eckerbom, *J. Chromat.*, 1984, 306; *Biomed. Appl.*, 31, 147–153.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: chloroquine, monodesethylchloroquine and didesethylchloroquine, sensitivity 5 ng for all compounds, UV detection—N. D. Brown *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 248–254. In plasma, erythrocytes or urine: chloroquine and monodesethylchloroquine, detection limits 1 ng/ml for chloroquine and 500 pg/ml for monodesethylchloroquine in plasma, fluorescence detection—G. Alvan *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 241–247.

Disposition in the Body. Rapidly absorbed after oral administration; bioavailability about 80 to 90%. Metabolic reactions include *N*-dealkylation and deamination followed by conjugation, possibly with glucuronic acid, of the carboxylic acid metabolites; the metabolites include monodesethyl- and didesethylchloroquine, 4-(7-chloroquinol-4-ylamino)pentan-1-ol, and 4-(7-chloroquinol-4-ylamino)pentanoic acid and its conjugate. Chloroquine is excreted slowly and may persist in the tissues for prolonged periods; about 55% is excreted in the urine and about 10% is eliminated in the faeces in 90 days following therapy with 310 mg of the phosphate daily for 14 days; the urinary excretion of unchanged drug is dependent upon urinary pH and larger amounts are excreted in acid urine than in alkaline urine; of the material excreted in the urine, about 70% is unchanged, 23% is monodesethylchloroquine, 1 to 2% is didesethylchloroquine and an unidentified metabolite, and 1 to 2% is conjugated carboxylic acid metabolites.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.02 to 0.2 µg/ml.

Following a single oral dose of 300 mg to 11 subjects, peak plasma concentrations of 0.056 to 0.10 µg/ml (mean 0.08) of chloroquine and 0.01 to 0.02 µg/ml of monodesethylchloroquine were attained in 1 to 6 hours (L. L. Gustafsson *et al.*, *Br. J. clin. Pharmac.*, 1983, 15, 471–479).

TOXICITY. Doses as low as 1 g have caused deaths in children and fatalities have occurred in adults after the ingestion of 3 to 44 g. Plasma concentrations greater than 0.6 µg/ml may produce toxic effects and concentrations greater than 3 µg/ml may be fatal.

In a review of 9 fatal cases of overdose, the following concentrations were reported: brain 2.8 to 50 µg/g (mean 16), kidney 110 to 640 µg/g (mean 303), liver 200 to 750 µg/g (mean 410); in two cases the blood concentration was reported to be 30 µg/ml (F. W. Kiel, *J. Am. med. Ass.*, 1964, 190, 398–400).

In two fatal cases of overdosage in which about 3 g and 10 g, had been ingested, the postmortem concentrations were: blood 16 and 12.4 µg/ml, kidney 70 and 300 µg/g, liver 175 and 344 µg/g, liver blood 90 and 44 µg/ml, lung 38 and 98 µg/g, urine 20 and 68.4 µg/ml; in the second of these cases the antemortem blood concentration was reported to be 8.6 µg/ml (A. E. Robinson *et al.*, *J. Pharm. Pharmac.*, 1970, 22, 700-703). A 26-year-old woman died after ingesting an unknown quantity of chloroquine, possibly to induce abortion; postmortem concentrations were: blood 4.2 µg/ml, brain 3.8 µg/g, kidney 32.9 µg/g, liver 71 µg/g; alcohol was also present (A. Noirfalise, *Forens. Sci.*, 1978, 11, 177-179).

HALF-LIFE. Plasma half-life, about 25 to 60 days.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 0.3.

PROTEIN BINDING. In plasma, about 50 to 70%.

Dose. For an acute attack, the equivalent of 1.5 g of chloroquine over three days (900 mg on the first day); for suppression, 300 to 600 mg every 7 days.

Chlorothiazide

Diuretic

Synonym. Clorotiazida

Proprietary Names. Azide; Chlotride; Diubram; Diuret; Diuril; Diurilix; Diurone; Saluric. It is an ingredient of Aldoclor and Diupres.

6-Chloro-2*H*-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxide

$C_7H_6ClN_3O_4S_2 = 295.7$

CAS—58-94-6

A white crystalline powder. M.p. about 340°, with decomposition.

Practically **insoluble** in water, chloroform, and ether; soluble 1 in 650 of ethanol and 1 in 100 of acetone; freely soluble in dimethylformamide and dimethyl sulphoxide.

Chlorothiazide Sodium

Synonym. Sodium Chlorothiazide

Proprietary Name. Diuril (injection)

$C_7H_5ClN_3NaO_4S_2 = 317.7$

CAS—7085-44-1

A crystalline solid.

Soluble in water.

Dissociation Constant. pK_a 6.7, 9.5 (20°).

Partition Coefficient. Log *P* (ether/pH 7.4), -1.9.

Colour Tests. Koppányi-Zwicker Test—blue; Mercurous Nitrate—black.

Thin-layer Chromatography. System TD—Rf 02; system TE—Rf 02; system TF—Rf 16. (Mercuric chloride-diphenylcarbazone reagent, positive.)

High Pressure Liquid Chromatography. System HN— k' 0.54.

Ultraviolet Spectrum. Aqueous acid—278 nm ($A_1^1 = 400$ a); aqueous alkali—292 nm ($A_1^1 = 430$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1157, 1305, 1595, 1090, 1123, 1620 (KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: chlorothiazide or hydrochlorothiazide, sensitivity 10 ng/ml in plasma and 2 µg/ml in urine, UV detection—R. H. Barbhaiya *et al.*, *J. pharm. Sci.*, 1981, 70, 291-295.

Disposition in the Body. Poorly and erratically absorbed after oral administration; bioavailability, about 20 to 30% after doses of 250 mg, decreasing with increasing dose. Chlorothiazide is not significantly metabolised and is excreted in the urine to a variable extent depending on the extent of absorption.

THERAPEUTIC CONCENTRATION.

Following single oral doses of 125, 250, and 500 mg to 12 subjects, mean peak plasma concentrations of 0.64, 0.92, and 1.3 µg/ml were attained in about 1 hour (P. G. Welling *et al.*, *Curr. ther. Res.*, 1982, 31, 379-385).

HALF-LIFE. Plasma half-life, about 1.5 hours.

PROTEIN BINDING. In plasma, about 95%.

Dose. 0.5 to 2 g daily.

Chlorotrianisene

Oestrogen

Synonym. Tri-*p*-anisylchloroethylene

Proprietary Names. Anisene; Chlorotrisin; Merbentul; Tace; Triagen.

Chlorotris(4-methoxyphenyl)ethylene

 $C_{23}H_{21}ClO_3 = 380.9$

CAS—569-57-3

Small white crystals or crystalline powder. M.p. about 118°.

Soluble 1 in 4200 of water, 1 in 360 of ethanol, 1 in 7 of acetone, 1 in 1.5 of chloroform, and 1 in 28 of ether.**Caution.** Chlorotrianisene is a powerful oestrogen. Contact with the skin or inhalation should be avoided.**Colour Tests.** Liebermann's Test—green; Sulphuric Acid—violet.**Thin-layer Chromatography.** System TP—Rf 88; system TQ—Rf 77; system TR—Rf 98; system TS—Rf 92.**Ultraviolet Spectrum.** Ethanol—247 nm ($A_1^1 = 635$ a), 307 nm ($A_1^1 = 410$ a).**Infra-red Spectrum.** Principal peaks at wavenumbers 1250, 1510, 1606, 1174, 813, 1184 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 380, 223, 382, 238, 152, 345, 215, 113.**Dose.** 12 to 24 mg daily.**Chloroxylenol**

Disinfectant

Synonyms. Parachlorometaxylenol; PCMX.

Proprietary Names. Dettol; Metasep.

4-Chloro-3,5-dimethylphenol

 $C_8H_9ClO = 156.6$

CAS—88-04-0

White or cream-coloured crystals or crystalline powder. Volatile in steam. M.p. 114° to 116°.

Soluble 1 in 3000 of water, 1 in 200 of boiling water, and 1 in 1 of ethanol; soluble in ether.**Colour Test.** Liebermann's Test—black.**Ultraviolet Spectrum.** Aqueous acid—279 nm ($A_1^1 = 83$ a); aqueous alkali—242 nm ($A_1^1 = 650$ a), 296 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1158, 1317, 1590, 1020, 858, 848 (KCl disk).**Disposition in the Body.** About 14% of ingested chloroxylenol is excreted in the urine as a glucuronide conjugate and 17% as the sulphate, together with traces of unchanged chloroxylenol; the amount of unchanged chloroxylenol excreted is increased if the urine is alkaline.**TOXICITY.**In a fatality due to the ingestion of at least 100 ml of a solution containing 4.8% w/v of chloroxylenol, postmortem chloroxylenol concentrations were as follows: blood 23 µg/ml, liver 8 µg/g (A. Coutselinis and D. Boukis, *Medicine, Sci. Law*, 1976, 16, 180).A subject who had ingested about 17 g of chloroxylenol in solution was admitted to hospital 30 minutes afterwards and recovered after intensive treatment (P. Joubert *et al.*, *Br. med. J.*, 1978, 1, 890).**Use.** Chloroxylenol is available in concentrations of about 5% w/v; it is further diluted before use.**Chlorphenesin**

Antifungal

Synonym. *p*-Chlorophenyl α -Glyceryl Ether

Proprietary Names. Mycil; Soorphenesin.

3-(4-Chlorophenoxy)propane-1,2-diol

 $C_9H_{11}ClO_3 = 202.6$

CAS—104-29-0

White or pale cream-coloured crystals or crystalline aggregates. M.p. 78° to 81°.

Soluble 1 in 200 of water and 1 in 5 of ethanol; soluble in ether.

Colour Tests. Liebermann's Test—black; Mandelin's Test—brown-green.

Thin-layer Chromatography. System TA—Rf 82. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1677.

Ultraviolet Spectrum. Methanol—281 nm ($A_1^1 = 79$ b), 289 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1232, 1043, 818, 1109, 1490, 710 (KBr disk).

Mass Spectrum. Principal peaks at m/z 128, 130, 202, 31, 29, 65, 43, 111.

Use. Topically in concentrations of 0.5 to 1%.

Chlorphenesin Carbamate

Muscle Relaxant

Proprietary Name. Maolate

3-(4-Chlorophenoxy)propane-1,2-diol 1-carbamate

$C_{10}H_{12}ClNO_4 = 245.7$

CAS—886-74-8

A white crystalline powder. M.p. about 90°.

Practically **insoluble** in water; soluble in ethanol, acetone, and chloroform.

Thin-layer Chromatography. System TD—Rf 11; system TE—Rf 53; system TF—Rf 34. (Furfuraldehyde reagent, positive.)

Ultraviolet Spectrum. Ethanol—280 nm ($A_1^1 = 75$ b), 288 nm ($A_1^1 = 62$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1724, 1234, 1028, 1692, 1111, 824 (KBr disk).

Mass Spectrum. Principal peaks at m/z 128, 130, 202, 43, 129, 111, 75, 204.

Quantification. COLORIMETRY. In serum—A. A. Forist and R. W. Judy, *J. pharm. Sci.*, 1971, 60, 1686–1688.

GAS CHROMATOGRAPHY. In serum: sensitivity 500 ng/ml, FID—D. G. Kaiser and S. R. Shaw, *J. pharm. Sci.*, 1974, 63, 1094–1097.

Disposition in the Body. Readily absorbed after oral administration. About 85% of a dose is excreted in the urine as a glucuronide conjugate in 24 hours together with small amounts of unchanged drug, and the oxidised metabolites, 4-chlorophenoxyacetic acid, 4-chlorophenoxyacetic acid and 4-chlorophenol.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 800 mg to 10 subjects, peak serum concentrations of 3.9 to 17.0 $\mu\text{g/ml}$ (mean 10) were attained in about 2 hours; after daily oral dosing with 800 mg three times a day for 11 weeks to the same subjects, a mean peak serum concentration of 14.4 $\mu\text{g/ml}$ was reported about 2 hours after the last dose (R. G. Stoll *et al.*, *J. clin. Pharmac.*, 1974, 14, 520–524).

HALF-LIFE. Plasma half-life, about 2 to 5 hours.

VOLUME OF DISTRIBUTION. About 1 litre/kg.

Dose. Initially 2.4 g daily, reduced to 1.6 g daily or less.

Chlorpheniramine

Antihistamine

Synonyms. Chlorphenamine; Chlorprophenpyridamine.

(\pm)-3-(4-Chlorophenyl)-*NN*-dimethyl-3-(2-pyridyl)propylamine

$C_{16}H_{19}ClN_2 = 274.8$

CAS—132-22-9; 42882-96-2 (\pm)

An oily liquid.

Chlorpheniramine Maleate

Proprietary Names. Allergex; AL-R; Alunex; Bramahist; Chlor-100; Chloramin; Chlor-Mal; Chlormene; Chlorspan; Chlortab; Chlor-Tri-meton; Chlor-Tripolon; Drize; Histoids; Histalon; Histaspan; Lorphen; Niratron; Novopheniram; Piriton; Teldrin. It is an ingredient of Colrex Compound, Coriforte, CoTylenol, Deconamine, Demazin, Dristan (tablets), Expulin, Fedahist, Haymine, Intensin, Naldecon, Neotep, Sancos Co, Sine-Off, and Triocos.

Note. The name Chloramin has been applied to chloramine.

$C_{16}H_{19}ClN_2 \cdot C_4H_4O_4 = 390.9$

CAS—113-92-8

A white crystalline powder. M.p. 130° to 135°.

Soluble 1 in 4 of water, 1 in 10 of ethanol, and 1 in 10 of chloroform; slightly soluble in ether.

Dissociation Constant. pK_a 9.1 (25°).

Colour Test. Cyanogen Bromide—orange.

Thin-layer Chromatography. System TA—Rf 45; system TB—Rf 33; system TC—Rf 18. (Dragendorff spray, positive; FPN reagent, blue; acidified iodoplatinate solution, positive; Marquis reagent, violet; ninhydrin spray, positive.)

Gas Chromatography. System GA—RI 2002; system GB—RI 2038; system GC—RI 2586; system GF—RI 2335.

High Pressure Liquid Chromatography. System HA— k' 3.9.

Ultraviolet Spectrum. Aqueous acid—265 nm ($A_1^1 = 302$ a); aqueous alkali—262 nm ($A_1^1 = 205$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1585, 1086, 746, 1010, 830, 1562 (KBr disk).

Mass Spectrum. Principal peaks at m/z 203, 58, 44, 205, 54, 204, 72, 202.

Quantification. GAS CHROMATOGRAPHY. In urine: sensitivity <60 ng, FID—H. M. Ali and A. H. Beckett, *J. Chromat.*, 1981, 223; *Biomed. Appl.*, 12, 208–212. In serum: sensitivity 0.5

to 1 ng/ml, ECD—J. W. Barnhart and J. D. Johnson, *Analyt. Chem.*, 1977, 49, 1085–1086.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma, saliva or urine: chlorpheniramine and two metabolites, sensitivity 2 ng/ml in plasma for chlorpheniramine, UV detection—N. K. Athanikar *et al.*, *J. Chromat.*, 1979, 162; *Biomed. Appl.*, 4, 367–376.

RADIOIMMUNOASSAY. In plasma: sensitivity 156 pg/ml—K. K. Midha *et al.*, *J. pharm. Sci.*, 1984, 73, 1144–1147.

Disposition in the Body. Readily and almost completely absorbed after oral administration, but extensively metabolised to polar and non-polar metabolites; bioavailability about 35%. The major metabolites are monodesmethyl- and didesmethylchlorpheniramine. About 35% of a single dose is excreted in the urine in 48 hours; the 24-hour excretion of unchanged drug accounts for about 3 to 10% of the dose but this is increased by acidification of the urine and increased urinary flow, and decreased when the urine is alkaline; more non-polar metabolites appear to be excreted after intravenous than after oral administration. After daily oral administration, about 20% of a dose is excreted in the 24-hour urine as unchanged drug, 20% as monodesmethylchlorpheniramine, and 5% as didesmethylchlorpheniramine. Less than 1% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 8 mg to 5 subjects, peak plasma concentrations of 0.01 to 0.04 $\mu\text{g/ml}$ (mean 0.02) were attained in 2 to 3 hours; after repeated oral administration of 6 mg twice a day to 2 subjects, mean plasma steady-state concentrations of 0.02 and 0.03 $\mu\text{g/ml}$ were reported; the plasma concentration of monodesmethylchlorpheniramine averaged 0.008 $\mu\text{g/ml}$ and plasma concentrations of didesmethylchlorpheniramine were less than 0.003 $\mu\text{g/ml}$ (S. M. Huang *et al.*, *Eur. J. clin. Pharmac.*, 1982, 22, 359–365).

TOXICITY. Toxic effects may be produced by plasma concentrations greater than 20 $\mu\text{g/ml}$.

The following postmortem tissue concentrations were reported in a fatality due to the ingestion of chlorpheniramine and alcohol: blood 1.1 $\mu\text{g/ml}$, bile 1.5 $\mu\text{g/ml}$, brain 2.5 $\mu\text{g/g}$, kidney 1.4 $\mu\text{g/g}$, liver 6.6 $\mu\text{g/g}$, lung 5.2 $\mu\text{g/g}$; a blood-alcohol concentration of 1200 $\mu\text{g/ml}$ was also reported (D. Reed, *Clin. Toxicol.*, 1981, 18, 941–943).

HALF-LIFE. Plasma half-life, 18 to 40 hours (mean 25); decreased in children.

VOLUME OF DISTRIBUTION. About 3 litres/kg.

CLEARANCE. Plasma clearance, about 1.5 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma : whole blood ratio, about 0.83.

PROTEIN BINDING. In plasma, about 70%.

Dose. 12 to 16 mg of chlorpheniramine maleate daily; up to 36 mg daily has been given in sustained-release preparations.

Chlorphenoxamine

Anticholinergic

2-(4-Chloro- α -methylbenzhydryloxy)-*NN*-dimethylethylamine

$C_{18}H_{22}ClNO = 303.8$

CAS—77-38-3

An oil.

Chlorphenoxamine Hydrochloride

Proprietary Names. Phenoxene; Systral.

$C_{18}H_{22}ClNO \cdot HCl = 340.3$

CAS—562-09-4

A white crystalline powder. M.p. 130° to 135°.

Soluble 1 in 2 of water, 1 in 1.8 of ethanol, and 1 in 1.5 of chloroform; practically insoluble in ether.

Colour Test. Marquis Test—yellow \rightarrow green.

Thin-layer Chromatography. *System TA*—Rf 53; *system TB*—Rf 47; *system TC*—Rf 36. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2072; *system GF*—RI 2365.

High Pressure Liquid Chromatography. *System HA*— k' 2.9.

Ultraviolet Spectrum. Aqueous acid—259 nm ($A_1^{1\%} = 16$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1088, 1490, 1010, 760, 700, 990 (chlorphenoxamine hydrochloride, KBr disk).

Wavelength

Mass Spectrum. Principal peaks at m/z 58, 59, 179, 42, 178, 72, 77, 30.

Dose. 150 to 400 mg of chlorphenoxamine hydrochloride daily.

Chlorphentermine

Anorectic

4-Chloro- α -dimethylphenethylamine

$C_{10}H_{14}ClN = 183.7$

CAS—461-78-9

A liquid.

Chlorphentermine Hydrochloride

Proprietary Name. Pre-Sate

$C_{10}H_{14}ClN \cdot HCl = 220.1$

CAS—151-06-4

A white or off-white crystalline powder. M.p. about 234°.

Soluble in water and ethanol; sparingly soluble in chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 9.6.

Thin-layer Chromatography. *System TA*—Rf 44; *system TB*—Rf 18; *system TC*—Rf 17. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1342; *system GB*—RI 1410; *system GC*—RI 1725.

High Pressure Liquid Chromatography. *System HA*— k' 0.9; *system HC*— k' 0.82.

Ultraviolet Spectrum. Aqueous acid—259 nm, 267 nm ($A_1^1 = 11.6$ c), 274 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 818, 1493, 1092, 1020, 848, 754 (chlorphentermine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 42, 41, 125, 59, 30, 89, 168.

Quantification. GAS CHROMATOGRAPHY. In urine: chlorphentermine and metabolites, FID—A. H. Beckett and P. M. Bélanger, *Br. J. clin. Pharmac.*, 1977, 4, 193–200. In blood: sensitivity 25 ng/ml, FID—H. W. Jun and E. J. Triggs, *J. pharm. Sci.*, 1970, 59, 306–309.

Disposition in the Body. Absorbed after oral administration and metabolised mainly by *N*-oxidation and *N*-hydroxylation to nitro, nitroso, and hydroxylamine derivatives. Excretion in the urine is dependent upon urinary pH, a much greater proportion of unchanged drug being excreted when the urine is acidic than when it is alkaline. In normal urine, about 17% of a dose is excreted unchanged and about 50% as *N*-oxidised metabolites in 48 hours. If the urine is maintained at an acid pH, these proportions are approximately reversed, about 70% of a dose being excreted in 24 hours. In alkaline urine less than 12% of a dose is excreted unchanged in 48 hours.

THERAPEUTIC CONCENTRATION.

A single oral dose of 100 mg given to 4 subjects produced a mean peak blood concentration of about 0.32 $\mu\text{g/ml}$ in 4 hours (H. W. Jun and E. J. Triggs, *ibid.*).

HALF-LIFE. Plasma half-life, about 40 hours.

VOLUME OF DISTRIBUTION. About 2 to 3 litres/kg.

Dose. Usually the equivalent of 65 mg of chlorphentermine daily.

Chlorproguanil

Antimalarial

1-(3,4-Dichlorophenyl)-5-isopropylbiguanide

$\text{C}_{11}\text{H}_{15}\text{Cl}_2\text{N}_5 = 288.2$

CAS—537-21-3

Chlorproguanil Hydrochloride

Proprietary Name. Lapudrine

$\text{C}_{11}\text{H}_{15}\text{Cl}_2\text{N}_5\cdot\text{HCl} = 324.6$

CAS—15537-76-5

A white crystalline powder. M.p. 246° to 247°.

Soluble 1 in 140 of water and 1 in 50 of ethanol; practically insoluble in chloroform and ether.

Colour Tests. To 10 ml of a saturated aqueous solution add 1 drop of 10% copper sulphate solution and 2.5 ml of *dilute ammonia solution* and shake well; add 5 ml of toluene and shake again—toluene layer is violet-red. Dissolve 5 mg in 5 ml of a warm 1% solution of cetrimide in water, add 1 ml of *sodium hydroxide solution* and 1 ml of *bromine solution*—red.

Thin-layer Chromatography. *System TA*—Rf 03; *system TB*—Rf 00; *system TC*—Rf 01. (*Acidified potassium permanganate solution*, positive.)

Gas Chromatography. *System GA*—RI 1621.

Ultraviolet Spectrum. Aqueous acid—250 nm ($A_1^1 = 293$ c); methanol—260 nm ($A_1^1 = 755$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1520, 1562, 1620, 1600, 1128, 1290 (chlorproguanil hydrochloride, KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 127, 43, 229, 44, 161, 231, 85, 186.

Dose. 20 mg of chlorproguanil hydrochloride every 7 days.

Chlorpromazine

Tranquilliser

Proprietary Names. Largactil (suppositories); Procalm; Thorazine (suppositories).

3-(2-Chlorophenothiazin-10-yl)-*NN*-dimethylpropylamine

$C_{17}H_{19}ClN_2S$ = 318.9

CAS—50-53-3

A white to creamy-white powder or waxy solid. It darkens on prolonged exposure to light. M.p. 56° to 60°.

Practically **insoluble** in water; soluble 1 in 2 of ethanol, 1 in less than 1 of chloroform, and 1 in 1 of ether.

Caution. Chlorpromazine may cause severe dermatitis in sensitised persons.

Chlorpromazine Embonate

Proprietary Name. Largactil (suspension)

$(C_{17}H_{19}ClN_2S)_2 \cdot C_{23}H_{16}O_6$ = 1026

A pale yellow powder.

Very slightly **soluble** in water; soluble in acetone.

Chlorpromazine Hydrochloride

Synonym. Aminazine

Proprietary Names. Chloractil; Chlorprom; Chlor-Promanyl; Dozine; Largactil; Promachlor; Promacid; Promapar; Protran; Sonazine; Thorazine.

$C_{17}H_{19}ClN_2S \cdot HCl$ = 355.3

CAS—69-09-0

A white or creamy-white crystalline powder. It decomposes on exposure to air and light becoming yellow, pink, and finally violet. M.p. 195° to 198°.

Soluble 1 in 0.4 of water, 1 in 1.4 of ethanol, and 1 in 1 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 9.3 (20°).

Partition Coefficient. Log *P* (octanol/pH 7.4), 3.4.

Colour Tests. Formaldehyde-Sulphuric Acid—red-violet; Forest Reagent—red; FPN Reagent—red; Liebermann's Test—red-brown; Mandelin's Test—green → violet; Marquis Test—violet.

Thin-layer Chromatography. System *TA*—Rf 49; system *TB*—Rf 49; system *TC*—Rf 35. (*Dragendorff* spray, positive; *FPN* reagent, pink; *acidified iodoplatinate* solution, positive; *Marquis* reagent, pink.)

Gas Chromatography. System *GA*—chlorpromazine RI 2486, monodesmethylchlorpromazine RI 2480, didesmethylchlorpromazine RI 2480; system *GF*—RI 2940.

High Pressure Liquid Chromatography. System *HA*—chlorpromazine *k'* 4.1, monodesmethylchlorpromazine *k'* 2.2.

Ultraviolet Spectrum. Aqueous acid—255 nm (A_1^1 = 1025 a). Chlorpromazine sulphoxide: aqueous acid—239 nm (A_1^1 = 1107 b), 274 nm (A_1^1 = 343 b), 300 nm (A_1^1 = 232 b), 341 nm (A_1^1 = 168 b).

Infra-red Spectrum. Principal peaks at wavenumbers 747, 1240, 1561, 1125, 1095, 1220 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 58, 86, 318, 85, 320, 272, 319, 273.

Quantification. GAS CHROMATOGRAPHY. In serum: sensitivity 5 ng/ml for chlorpromazine and chlorpromazine sulphoxide, 20 ng/ml for monodesmethylchlorpromazine and 10 ng/ml for didesmethylchlorpromazine, AFID—D. N. Bailey and J. J. Guba, *Clin. Chem.*, 1979, 25, 1211–1215.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In plasma or tissues: limit of detection 1 ng/ml for chlorpromazine, monodes-

methylchlorpromazine and 7-hydroxychlorpromazine in plasma—G. Alfredsson *et al.*, *Psychopharmacology*, 1976, 48, 123–131.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 1 ng/ml, UV detection—K. K. Midha *et al.*, *J. pharm. Sci.*, 1981, 70, 1043–1046. In plasma: sensitivity 250 pg/ml, electrochemical detection—J. K. Cooper *et al.*, *J. pharm. Sci.*, 1983, 72, 1259–1262. In postmortem samples: chlorpromazine and metabolites, UV detection—W. J. Allender *et al.*, *J. analyt. Toxicol.*, 1983, 7, 203–206.

RADIOIMMUNOASSAY. In plasma: sensitivity 200 pg/ml—K. K. Midha *et al.*, *Clin. Chem.*, 1979, 25, 166–168.

Disposition in the Body. Readily absorbed after oral administration, but extensively metabolised by sulphoxidation, *N*-demethylation, hydroxylation, *N*-oxidation, glucuronic acid conjugation, and possibly ring fission; bioavailability about 20 to 30%, reduced during chronic therapy. A large number of metabolites have been isolated and some of the metabolites are active, particularly 7-hydroxychlorpromazine, although less so than the parent drug; several metabolites may be detected in plasma at concentrations similar to those of chlorpromazine during chronic treatment. Chlorpromazine may stimulate the drug-metabolising enzymes of the liver and may therefore stimulate its own metabolism. About 20 to 70% of an oral dose is excreted in the urine as metabolites, mostly conjugated, with 5% of the dose as the sulphoxide, and less than 1% as unchanged drug; about 5% of a dose is eliminated in the faeces as metabolites. Chlorpromazine metabolites have been detected in urine up to 18 months after discontinuation of long-term treatment. The monodesmethyl-, 7-hydroxy-, and sulphoxide metabolites are taken up by erythrocytes along with traces of the parent drug and its *N*-oxide.

THERAPEUTIC CONCENTRATION. Plasma concentrations vary considerably between individual subjects.

Peak plasma concentrations of 0.010 to 0.026 µg/ml (mean 0.018) were reported 3 hours after administration of a single oral dose of 150 mg to 6 subjects (L. E. Hollister *et al.*, *Clin. Pharmac. Ther.*, 1970, 11, 49–59).

Following daily oral doses of 200 to 600 mg to 10 subjects, minimum steady-state plasma concentrations of 0.002 to 0.122 µg/ml (mean 0.03) of chlorpromazine were reported; monodesmethylchlorpromazine and 7-hydroxychlorpromazine plasma concentrations averaged 16% and 30% respectively of the chlorpromazine plasma concentration, but there were considerable intersubject variations (G. Alfredsson *et al.*, *Psychopharmacology*, 1976, 48, 123–131).

TOXICITY. Severe toxic symptoms have occurred with doses of less than 0.1 g. Overdosage with chlorpromazine is a fairly common occurrence, but fatalities are relatively rare. Blood concentrations in the region of 0.5 to 2 µg/ml are associated with toxic effects and concentrations of 2 µg/ml or greater may be lethal.

In a review of 8 fatal cases, blood concentrations of 3 to 35 µg/ml (mean 17), and liver concentrations of 54 to 2110 µg/g (mean 366) were reported (R. Bonnichsen *et al.*, *Z. Rechtsmed.*, 1970, 67, 158–169).

The following tissue distribution was reported in 2 fatalities: blood 4.2 and 6.7 µg/ml, brain 126 and 148 µg/g, kidney 134 and 162 µg/g, liver 240 and 280 µg/g, urine 62 and 78 µg/ml (A. Coutselinis *et al.*, *Forens. Sci.*, 1974, 4, 191–194).

HALF-LIFE. Plasma half-life, 7 to 120 hours; mean values are usually in the range 15 to 30 hours.

PROTEIN BINDING. In plasma, about 95 to 98%.

NOTE. For a review of the pharmacokinetics of antipsychotics see T. B. Cooper, *Clin. Pharmacokinet.*, 1978, 3, 14–38.

Dose. 75 to 300 mg of chlorpromazine hydrochloride daily; 1 g or more daily has been given to psychotic patients.

Chlorpropamide

Antidiabetic

Synonym. Chloglypropamide

Proprietary Names. Chloromide; Chloronase; Diabetoral; Diabinese; Glymese; Insulase; Melitase; Mellinese; Novopropamide; Promide; Stabinol.

1-(4-Chlorobenzenesulphonyl)-3-propylurea

C₁₀H₁₃ClN₂O₃S = 276.7

CAS—94-20-2

A white crystalline powder. M.p. 126° to 130°.

Practically **insoluble** in water; soluble 1 in 12 of ethanol, 1 in 5 of acetone, 1 in 9 of chloroform, and 1 in 200 of ether.

Dissociation Constant. pK_a 5.0 (20°).

Colour Tests. Koppanyi–Zwikker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. System TA—Rf 72; system TD—Rf 38; system TE—Rf 11; system TF—Rf 43; system TT—Rf 84; system TU—Rf 43; system TV—Rf 03.

Gas Chromatography. System GA—RI 1791.

Ultraviolet Spectrum. Methanolic acid—232 nm (A₁¹ = 598 a).

Infra-red Spectrum. Principal peaks at wavenumbers 1661, 1159, 1553, 757, 1086, 909 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 111, 175, 75, 85, 30, 276, 127, 113.

Quantification. GAS CHROMATOGRAPHY. In plasma: chlorpropamide or tolbutamide, detection limit 50 ng/ml, FID—K. K. Midha *et al.*, *J. pharm. Sci.*, 1976, 65, 576–579. In blood or plasma: chlorpropamide or tolbutamide, sensitivity 1 µg/ml, ECD—S. B. Matin and M. Rowland, *J. Pharm. Pharmac.*, 1973, 25, 186–187.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum: chlorpropamide or tolbutamide, sensitivity 7 µg/ml for chlorpropamide, UV detection—R. E. Hill and J. Crechiolo, *J. Chromat.*, 1978, 145; *Biomed. Appl.*, 2, 165–168. In urine: chlorpropamide and metabolites, using initial separation by thin-layer chromatography, UV detection—J. A. Taylor, *Clin. Pharmac. Ther.*, 1972, 13, 710–718.

Disposition in the Body. Rapidly and completely absorbed after oral administration. The main metabolic reactions are hydroxylation at the 2- and 3- positions of the propyl substituent in the side-chain, *N*-dealkylation, and hydrolysis to form the sulphonamide metabolite. About 80% of a single oral dose is excreted in the urine in 7 days. During chronic therapy, up to 100% of a dose is excreted in the urine in 24 hours, with about 18% of the dose as unchanged drug, 2% as 4-chlorobenzenesulphonamide, 20% as 4-chlorobenzenesulphonylurea, 55% as 2-hydroxychlorpropamide, and 2% as 3-hydroxychlorpropamide.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 30 to 250 µg/ml.

Following single oral doses of 250 mg to 6 subjects, peak plasma concentrations of 23.9 to 39.4 µg/ml (mean 28) were attained in 1 to 7 hours. After daily oral doses of 250 to 500 mg to 4 subjects, steady-state plasma concentrations of 75.5 to 245.5 µg/ml (mean 142) were reported; plasma concentrations of 4-chlorobenzenesulphonylurea and 2-hydroxychlorpropamide ranged from 3 to 6 µg/ml and < 1 to 9 µg/ml, respectively (J. A. Taylor, *Clin. Pharmac. Ther.*, 1972, 13, 710–718).

TOXICITY. Prolonged hypoglycaemic coma has been reported after overdosage but fatalities are comparatively rare, although some instances of fatal blood dyscrasias have been reported. Peak plasma concentrations of 200 to 750 µg/ml have been observed in comatose subjects.

HALF-LIFE. Plasma half-life, 20 to 45 hours (mean 35); increased in renal impairment.

VOLUME OF DISTRIBUTION. About 0.1 to 0.3 litre/kg.

PROTEIN BINDING. In plasma, 60 to 95%.

Dose. 100 to 500 mg daily.

Chlorprothixene

Tranquilliser

Proprietary Names. Taractan; Tarasan; Truxal; Truxaletten.

(*Z*)-3-(2-Chlorothioxanthen-9-ylidene)-*NN*-dimethylpropylamine

C₁₈H₁₈ClNS = 315.9

CAS—113-59-7

A yellow crystalline powder. M.p. 96.5° to 101.5°.

Soluble 1 in 1700 of water, 1 in 29 of ethanol, 1 in 18 of acetone, 1 in 2 of chloroform, and 1 in 14 of ether.

Dissociation Constant. pK_a 8.8.

Partition Coefficient. Log *P* (octanol/pH 7.0), 2.7.

Colour Tests. Formaldehyde-Sulphuric Acid—red (orange fluorescence under ultraviolet light); Liebermann's Test—red; Mandelin's Test—red; Marquis Test—red-orange; Sulphuric Acid—orange (fluoresces under ultraviolet light).

Thin-layer Chromatography. System *TA*—Rf 56; system *TB*—Rf 51; system *TC*—Rf 51. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2487; system *GF*—RI 2910.

High Pressure Liquid Chromatography. System *HA*—k' 3.0.

Ultraviolet Spectrum. Aqueous acid—230 nm (*A*₁¹ = 1096 b), 268 nm, 324 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 776, 1104, 832, 746, 1030, 1170 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 58, 59, 221, 30, 42, 222, 255, 43.

Quantification. SPECTROFLUORIMETRY. In plasma—T. Mjörndal and L. Orelund, *Acta pharmac. tox.*, 1971, 29, 295–302. In blood: sensitivity 1 ng/ml—J. Raaflaub, *Experientia*, 1975, 31, 557–558.

ULTRAVIOLET SPECTROPHOTOMETRY. In blood, liver or urine: chlorprothixene and metabolites, sensitivity 500 ng/g, separation by thin-layer chromatography—H. Christensen, *Acta pharmac. tox.*, 1974, 34, 16–26.

Disposition in the Body. Readily absorbed after oral administration, but undergoes extensive first-pass metabolism; bioavailability about 40%. The major metabolite is the sulphoxide, but *N*-demethylation and *N*-oxidation also occur. After daily oral doses, up to about 30% is excreted in the urine in 24 hours as chlorprothixene sulphoxide, and up to about 40% is eliminated in the faeces also as the sulphoxide.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 30 mg to one subject, a peak blood concentration of about 0.01 µg/ml was attained in 4 hours (J. Raaflaub, *Experientia*, 1975, 31, 557–558).

TOXICITY. The estimated minimum lethal dose is 2.5 g, although recovery has occurred after the ingestion of 12 g.

In 6 fatalities attributed to the ingestion of about 2.5 to 4 g of chlorprothixene, the following postmortem concentrations were reported: blood, chlorprothixene <0.1 to 0.4 µg/ml, total metabolites <0.1 to 0.6 µg/ml; liver, chlorprothixene 5 to 42 µg/g (mean 18), total metabolites 14 to 67 µg/g (mean 25); in 1 case a urine concentration of total thioxanthenes of 15 µg/ml was also reported; desmethylchlorprothixene was the major metabolite in the liver. Alcohol was also detected in 3 cases (H. Christensen, *Acta pharmac. tox.*, 1974, 34, 16–26).

In a fatality involving the ingestion of up to 4 g of chlorprothixene, the following postmortem tissue concentrations were reported (µg/ml):

	Chlorprothixene	Chlorprothixene sulphoxide
Blood	0.1	0.6
Bile	3.9	7.0
Urine	0.4	3.4

(A. Poklis *et al.*, *J. analyt. Toxicol.*, 1983, 7, 29–32).

HALF-LIFE. Plasma half-life, about 8 to 12 hours.

VOLUME OF DISTRIBUTION. About 10 to 20 litres/kg

CLEARANCE. Plasma clearance, about 14 to 20 ml/min/kg.

Dose. 75 to 200 mg daily; up to 600 mg daily has been given.

Chlorquinaldol

Antibacterial/Antifungal

Synonyms. Chlorchinaldol; Hydroxydichloroquinaldine.

Proprietary Names. Gyno-Sterosan; Gynotherax; Siogen(o); Siosteran; Sterosan; Steroxin.

5,7-Dichloro-2-methylquinolin-8-ol

$C_{10}H_7Cl_2NO = 228.1$

CAS—72-80-0

A green or yellowish-brown crystalline powder. M.p. about 113°. Practically **insoluble** in water; soluble 1 in 100 of ethanol, 1 in 20 of chloroform, and 1 in 33 of ether; soluble in acetone.

Colour Test. Ferric Chloride—blue-green.

Thin-layer Chromatography. System TA—Rf 71. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1802.

Ultraviolet Spectrum. Aqueous acid—263 nm ($A_1^1 = 2100$ b), 330 nm ($A_1^1 = 132$ b); aqueous alkali—263 nm ($A_1^1 = 1410$ b), 345 nm ($A_1^1 = 186$ b); methanol—251 nm ($A_1^1 = 1900$ b), 315 nm ($A_1^1 = 146$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1656, 1739, 1605, 758, 1111, 1153 (KBr disk).

Uses. Chlorquinaldol is used topically in a concentration of 3%; it has been used as 200-mg vaginal tablets.

Chlortetracycline

Antibiotic

7-Chlorotetracycline

$C_{22}H_{23}ClN_2O_8 = 478.9$

CAS—57-62-5

A yellow crystalline powder. M.p. 168° to 169°.

Very slightly **soluble** in water; slightly soluble in ethanol and acetone; practically insoluble in ether.

Chlortetracycline Calcium

CAS—5892-31-9

A white powder.

Practically **insoluble** in water.

Chlortetracycline Hydrochloride

Synonym. Biomycin

Proprietary Names. Aureomycin(e); Chlortet. It is an ingredient of Aureocort and Deteclo.

$C_{22}H_{23}ClN_2O_8 \cdot HCl = 515.3$

CAS—64-72-2

Yellow crystals. M.p. about 210°, with decomposition.

Soluble 1 in 75 to 1 in 110 of water and 1 in 250 to 1 in 560 of ethanol; practically insoluble in acetone, chloroform, and ether; soluble in solutions of alkali hydroxides and carbonates.

Dissociation Constant. pK_a 3.3, 7.4, 9.3 (25°).

Partition Coefficient. Log *P* (octanol/pH 7.5), −0.9.

Colour Tests. Benedict's Reagent—red; Formaldehyde-Sulphuric Acid—orange-brown; Mandelin's Test—violet-brown → yellow; Marquis Test—yellow → green; Sulphuric Acid—brown-blue.

Thin-layer Chromatography. System TA—Rf 05, streaking. (Location under ultraviolet light, orange fluorescence; acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—266 nm ($A_1^1 = 386$ a), 359 nm; aqueous alkali—253 nm, 284 nm, 346 nm. (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1622, 1580, 1666, 1311, 1041, 1227 (chlortetracycline hydrochloride, KBr disk). Polymorphism may occur.

Disposition in the Body. Readily absorbed after oral administration but rapidly inactivated in the body. It is eliminated mainly by biliary excretion with only about 15% of a dose being excreted in the urine as unchanged drug.

HALF-LIFE. Plasma half-life, about 6 hours.

PROTEIN BINDING. In plasma, about 47%.

Dose. 1 to 2 g of chlortetracycline hydrochloride daily.

Infra-red Spectrum. Principal peaks at wavenumbers 1685, 1033, 1160, 845, 1190, 1310 (KBr disk).

Chlorthalidone

Diuretic

Synonym. Chlortalidone

Proprietary Names. Hydro-long; Hygroton; Igrolina; Novothalidone; Renon; Uridon; Urolin; Zambesil. It is an ingredient of Kalspare, Lopresoretic, Regroton, and Tenoret(ic).

2 - Chloro - 5 - (1 - hydroxy - 3 - oxoisindolin - 1 - yl)benzenesulphonamide

$C_{14}H_{11}ClN_2O_4S = 338.8$

CAS—77-36-1

A white or yellowish-white crystalline powder. M.p. about 220°, with decomposition.

Practically **insoluble** in water; soluble 1 in 150 of ethanol, 1 in 650 of chloroform, and 1 in 25 of methanol; slightly soluble in ether; soluble in solutions of alkali hydroxides.

Dissociation Constant. pK_a 9.4.

Colour Tests. Koppanyi-Zwicker Test—violet; Marquis Test—yellow.

Thin-layer Chromatography. *System TD*—Rf 04; *system TE*—Rf 42; *system TF*—Rf 43.

Gas Chromatography. *System GA*—RI 2145.

High Pressure Liquid Chromatography. *System HN*—k' 1.28.

Ultraviolet Spectrum. Ethanol—275 nm ($A_1^1 = 57$ a), 284 nm ($A_1^1 = 45$ a).

Mass Spectrum. Principal peaks at m/z 76, 239, 104, 240, 285, 241, 50, 75.

Quantification. GAS CHROMATOGRAPHY. In plasma, erythrocytes or urine: sensitivity 10 ng/ml in plasma, AFID—H. L. J. Fleuren and J. M. van Rossum, *J. Chromat.*, 1978, 152, 41–54.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In blood, plasma or urine: sensitivity 30 ng/ml, UV detection—P. J. M. Guelen *et al.*, *J. Chromat.*, 1980, 181; *Biomed. Appl.*, 7, 497–503. In blood or urine: sensitivity 100 ng/ml, UV detection—T. R. MacGregor *et al.*, *Ther. Drug Monit.*, 1984, 6, 83–90.

Disposition in the Body. Readily but incompletely absorbed after oral administration; bioavailability about 65%. It does not appear to be significantly metabolised. After a single dose, about 25 to 40% is excreted in the urine as unchanged drug and about 1% is eliminated in the bile; the quantity excreted in the urine appears to be dose-dependent. During daily therapy, about 50% of the daily dose is excreted unchanged in the urine in 24 hours and about 25% is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After single oral doses of 50 to 75 mg given to 7 subjects, peak plasma concentrations of 0.14 to 0.26 µg/ml were attained in 1 to 3 hours (H. L. J. Fleuren *et al.*, *Eur. J. clin. Pharmac.*, 1979, 15, 35–50).

Following daily oral doses of 50 mg to 10 subjects, steady-state plasma concentrations of 0.2 to 1.4 µg/ml (mean 0.5) were reported (P. Collste *et al.*, *Eur. J. clin. Pharmacol.*, 1976, 9, 319–325).

HALF-LIFE. Plasma half-life, 35 to 70 hours (mean 48), increased in elderly subjects.

VOLUME OF DISTRIBUTION. About 4 litres/kg.

CLEARANCE. Plasma clearance, about 1 to 2 ml/min/kg.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, about 0.04 at therapeutic concentrations.

PROTEIN BINDING. In plasma, about 75%.

NOTE. For a review of the pharmacokinetics of diuretics, see B. Beerman and M. Groschinsky-Grind, *Clin. Pharmacokinet.*, 1980, 5, 221–245.

Dose. Usually 50 mg daily or 100 to 200 mg on alternate days.

Chlorzoxazone

Muscle Relaxant

Synonym. Chlorobenzoxazolinone

Proprietary Names. Biomioran; Paraflex. It is an ingredient of Parafon.

5-Chlorobenzoxazol-2(3H)-one

$C_7H_4ClNO_2$, 169.6

CAS—95-25-0

Colourless crystals or white crystalline powder. M.p. 190° to 194°.

Slightly **soluble** in water; soluble 1 in 20 of ethanol, 1 in 250 of chloroform, and 1 in 60 of ether; soluble in acetone and methanol.

Dissociation Constant. pK_a 8.0 (20°).

Colour Test. Koppanyi–Zwicker Test—violet.

Gas Chromatography. System GA—RI 1728.

Ultraviolet Spectrum. Aqueous acid—280 nm ($A_1^1 = 306$ a); aqueous alkali—243 nm ($A_1^1 = 580$ a), 287 nm ($A_1^1 = 409$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1762, 801, 962, 1149, 840, 1300 (KBr disk).

Mass Spectrum. Principal peaks at m/z 169, 78, 171, 113, 115, 63, 51, 170.

Quantification. SPECTROFLUORIMETRY. In plasma or urine: detection limits 60 ng/ml in plasma and 130 ng/ml in urine—J. T. Stewart and C. Chan, *J. pharm. Sci.*, 1979, 68, 910–912.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: chlorzoxazone and 6-hydroxychlorzoxazone, sensitivity 80 ng, UV detection—I. L. Honigberg *et al.*, *J. pharm. Sci.*, 1979, 68, 253–255.

Disposition in the Body. Absorbed after oral administration and rapidly metabolised to 6-hydroxychlorzoxazone. Up to 90% of a dose is excreted in the urine in 48 hours as conjugates of the 6-hydroxy metabolite; less than 1% is excreted as unchanged drug; 5-chloroacetanilide and 6-hydroxybenzoxazol-2(3H)-one have also been detected in urine.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 750 mg of chlorzoxazone and 900 mg of paracetamol, a mean peak plasma concentration of 36.3 µg/ml of chlorzoxazone was attained in 0.7 hour (R. K. Desiraju *et al.*, *J. pharm. Sci.*, 1983, 72, 991–994).

HALF-LIFE. Plasma half-life, about 1 hour.

Dose. 0.75 to 3 g daily.

Cholecalciferol

Vitamin

Synonyms. Activated 7-Dehydrocholesterol; Colecalciferol; Vitamin D₃.

Proprietary Names. D-Mulsin; D₃-Vicotrat forte; Neo-Dohyfral D₃.

(5Z,7E)-9,10-Secosteroid-5,7,10(19)-trien-3β-ol

$C_{27}H_{44}O$, 384.6

CAS—67-97-0

White crystals. It is affected by air and light and should be stored in a cool place in hermetically sealed containers in which the air has been replaced by an inert gas. Solutions in volatile solvents are unstable. M.p. about 84°.

Practically **insoluble** in water; freely soluble in ethanol, chloroform, and ether.

Colour Test. To a 10% solution in chloroform, add 0.3 ml of acetic anhydride and 0.1 ml of *sulphuric acid*—red → violet → blue-green.

Ultraviolet Spectrum. Ethanol—265 nm ($A_1^1 = 480$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1052, 894, 901, 967, 862, 1075 (KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: cholecalciferol, ergocalciferol and the 25-hydroxy metabolites, detection limit 500 pg/ml, UV detection—G. Jones, *Clin. Chem.*, 1978, 24, 287–298.

Disposition in the Body. Well absorbed after oral administration and subject to enterohepatic circulation; decreased absorption may occur in subjects with impaired liver and biliary function. Metabolised by hydroxylation to active metabolites. The major metabolite is 25-hydroxycholecalciferol which is formed in the liver. This is further metabolised by 1 α - or 24-hydroxylation in the kidneys. Most of a dose is excreted in the bile and eliminated in the faeces; about 25% of a dose is excreted as conjugates. Unchanged cholecalciferol does not appear to be excreted in the urine.

BLOOD CONCENTRATION. Normal serum concentrations of 25-hydroxycholecalciferol are about 0.015 to 0.040 μ g/ml, but there are considerable intersubject and seasonal variations.

HALF-LIFE. Plasma half-life, about 1 to 2 days; after intravenous administration a terminal elimination half-life of about 18 days has been reported.

PROTEIN BINDING. Bound to some extent to globulins and to lipoproteins.

Dose. 0.025 to 5 mg daily.

Cholesterol

Synonym. Cholesterin

Cholest-5-en-3 β -ol

$C_{27}H_{46}O = 386.7$

CAS—57-88-5

White or faintly yellow, pearly leaflets, needles, powder or granules. It acquires a yellow to pale tan colour on prolonged exposure to light. M.p. 147° to 150°.

Practically **insoluble** in water; slowly soluble 1 in 100 of ethanol and 1 in 50 of dehydrated alcohol; soluble in acetone, chloroform, dioxan, and ether.

Colour Tests. Antimony Pentachloride—orange → brown; Naphthol-Sulphuric Acid—yellow-brown/violet; Sulphuric Acid—orange.

To a solution of 10 mg in 1 ml of chloroform add 1 ml of *sulphuric acid*; chloroform layer—red, sulphuric acid layer—green fluorescence.

Dissolve about 5 mg in 2 ml of chloroform, add 1 ml of acetic anhydride and 1 drop of *sulphuric acid*—pink → red → blue → green.

Gas Chromatography. System GA—RI 3086; system GE—retention time 1.35 relative to phenytoin.

Infra-red Spectrum. Principal peaks at wavenumbers 1059, 1022, 800, 959, 952, 839 (Nujol mull).

Mass Spectrum. Principal peaks at m/z 386, 368, 43, 55, 275, 81, 57, 95.

Choline

Proprietary Name. Neurotropan

2-Hydroxyethyltrimethylammonium hydroxide

$C_5H_{15}NO_2 = 121.2$

CAS—62-49-7 (cation)

A colourless, viscid, hygroscopic, strongly alkaline liquid.

Very **soluble** in water and ethanol; practically insoluble in ether.

Choline Bitartrate

Synonym. Choline Acid Tartrate

$C_9H_{19}NO_7 = 253.3$

CAS—87-67-2

A white, hygroscopic, crystalline powder.

Very **soluble** in water; slightly soluble in ethanol; practically insoluble in chloroform and ether.

Choline Chloride

Proprietary Name. Becholine

$C_5H_{14}ClNO = 139.6$

CAS—67-48-1

White, very hygroscopic crystals.

Very **soluble** in water and ethanol; practically insoluble in chloroform and ether.

Choline Dihydrogen Citrate

Synonym. Choline Citrate

$C_{11}H_{21}NO_8 = 295.3$

CAS—77-91-8

Colourless, translucent, hygroscopic crystals or white crystalline powder.

M.p. 103° to 108°.

Soluble 1 in 1 of water and 1 in 45 of ethanol; very slightly soluble in chloroform and ether.

Dissociation Constant. pK_a 8.9.

Thin-layer Chromatography. System TA—Rf 02; system TN—Rf 60; system TO—Rf 60. (Acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1636, 1620, 953, 1075, 1040, 860 (choline chloride, thin film).

Quantification. COLORIMETRY. In urine—S. Eksborg and B. A. Persson, *Acta pharm. suec.*, 1971, 8, 605–608.

Disposition in the Body. Choline is a metabolite of suxamethonium chloride and suxethonium bromide.

Dose. Choline has been given in doses of 2 to 4 g daily.

Chromonar

Anti-anginal Vasodilator

Synonym. Carbocromen

Ethyl 3-(2-diethylaminoethyl)-4-methylcoumarin-7-yloxyacetate

$C_{20}H_{27}NO_5 = 361.4$

CAS—804-10-4

Practically **insoluble** in water; soluble in chloroform and ether.

Chromonar Hydrochloride

Synonym. Cassella 4489

Proprietary Name. Intensain

$C_{20}H_{27}NO_5 \cdot HCl = 397.9$

CAS—655-35-6

A white crystalline powder. M.p. about 159°.

Soluble in water, ethanol, and chloroform; sparingly soluble in ether.

Colour Tests. Aromaticity (Method 2)—yellow/orange; Liebermann's Test (100°)—blue (3 min); Sulphuric Acid—violet (blue fluorescence at 350 nm).

Thin-layer Chromatography. System TA—Rf 48; system TB—Rf 17; system TC—Rf 24. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2820.

Ultraviolet Spectrum. Aqueous acid—321 nm ($A_1^1 = 527$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1708, 1608, 1210, 1755, 1178, 1085 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 87, 58, 30, 29, 84, 56, 42.

Quantification. SPECTROFLUORIMETRY. In plasma or urine: sensitivity 40 ng/ml—Y. C. Martin and R. G. Wiegand, *J. pharm. Sci.*, 1970, 59, 1313–1318.

Disposition in the Body. Incompletely absorbed after oral administration (about 35%); rapidly hydrolysed to the corresponding carboxylic acid. About 70% of an intravenous dose and 20% of an oral dose is excreted in the 24-hour urine as the carboxylic acid metabolite.

THERAPEUTIC CONCENTRATION.

Following oral administration of 150 mg three times a day to 6 subjects, a peak plasma concentration of 0.9 µg/ml of the carboxylic acid metabolite was reported, declining to 0.06 µg/ml, 10 hours after the last dose (Y. C. Martin and R. G. Wiegand, *J. pharm. Sci.*, 1970, 59, 1313–1318).

HALF-LIFE. Plasma half-life, carboxylic acid metabolite about 0.8 hour.

VOLUME OF DISTRIBUTION. Carboxylic acid metabolite, about 0.4 litre/kg.

REFERENCE. Y. C. Martin and R. G. Wiegand, *J. pharm. Sci.*, 1970, 59, 1313–1318.

Dose. Chromonar hydrochloride has been given in doses of 225 to 675 mg daily.

Cimetidine

Histamine H₂-Receptor Antagonist

Proprietary Name. Tagamet

2-Cyano-1-methyl-3-[2-(5-methylimidazol-4-ylmethylthio)ethyl]guanidine

$C_{10}H_{16}N_6S = 252.3$

CAS—51481-61-9

A crystalline powder. M.p. about 142°.

Soluble 1 in about 88 of water.

Dissociation Constant. pK_a 6.8.

Colour Tests. Nessler's Reagent (100°)—black; Sodium Picrate—red.

Thin-layer Chromatography. System TA—Rf 54; system TB—Rf 00; system TC—Rf 09.

High Pressure Liquid Chromatography. System HA— k' 0.4.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1588, 1620, 1208, 1082, 1160, 1503 (KBr disk). Polymorphism may occur. (See below)

Mass Spectrum. Principal peaks at m/z 30, 57, 82, 116, 99, 53, 55, 42.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum or urine: cimetidine and metabolites, limit of detection 50 ng/ml for cimetidine, UV detection—J. A. Ziemniak *et al.*, *Clin. Chem.*, 1981, 27, 272–275. In plasma or urine: detection limit 25 ng/ml, UV detection—M. S. Ching *et al.*, *J. pharm. Sci.*, 1984, 73, 1015.

Disposition in the Body. Rapidly absorbed after oral administration; bioavailability about 70% but there is considerable intersubject variation. About 50 to 80% of an intravenous dose

is excreted in the urine as unchanged drug in 24 hours, together with about 10% as the sulfoxide metabolite and about 5% as the 5-hydroxymethyl derivative. Up to about 10% of the dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.5 to 1.5 µg/ml.

A single oral dose of 200 mg administered to 20 subjects, resulted in peak blood concentrations of 0.6 to 1.9 µg/ml (mean 1.1) in 1 to 2 hours (A. Redolfi *et al.*, *Eur. J. clin. Pharmac.*, 1979, 15, 257–261).

Following oral administration of 200 mg five times a day to 10 subjects, minimum steady-state plasma concentrations of 0.26 to 0.80 µg/ml (mean 0.4) were reported; steady-state plasma concentrations of the sulfoxide metabolite ranged from 0.07 to 0.21 µg/ml (mean 0.12) (R. Larsson, *Br. J. clin. Pharmac.*, 1982, 13, 163–170).

TOXICITY. Cimetidine appears to be relatively non-toxic; recovery has occurred after ingestion of 24 g in one dose, and ingestion of 60 g during 5 days caused no untoward effects. During chronic therapy, toxic effects are reportedly associated with trough plasma concentrations greater than 1.3 µg/ml.

In 3 cases of overdose due to the ingestion of 5.2, 16, and 19.6 g of cimetidine, plasma concentrations of 37, 57, and 36 µg/ml, respectively, were reported 2 to 3 hours after ingestion; the subjects all recovered (R. N. Illingworth and D. R. Jarvie, *Br. med. J.*, 1979, 1, 453–454).

In a fatality due to the ingestion of cimetidine and diazepam, postmortem blood concentrations of 110 µg/ml of cimetidine and 5.8 µg/ml of diazepam were reported (J. Hiss *et al.*, *Lancet*, 1982, 2, 982).

HALF-LIFE. Plasma half-life, 1 to 3 hours.

VOLUME OF DISTRIBUTION. About 1 to 2 litres/kg.

CLEARANCE. Plasma clearance, about 9 ml/min/kg; considerably reduced in elderly patients.

DISTRIBUTION IN BLOOD. Plasma : whole blood ratio, about 1.0.

PROTEIN BINDING. In plasma, 13 to 26%.

NOTE. For a review of the pharmacokinetics of cimetidine see A. Somogyi and R. Gugler, *Clin. Pharmacokinet.*, 1983, 8, 463–495.

Dose. 0.8 to 1.6 g daily; maximum of 2.4 g daily.

Cinchocaine

Local Anaesthetic

Synonyms. Cincaium; Dibucaine.

Proprietary Name. It is an ingredient of Biosone GA.

2-Butoxy-N-(2-diethylaminoethyl)quinoline-4-carboxamide

$C_{20}H_{29}N_3O_2 = 343.5$

CAS—85-79-0

A white, somewhat hygroscopic powder. M.p. 62° to 65.5°.

Soluble 1 in 4600 of water, 1 in less than 1 of ethanol and of chloroform, and 1 in 1.5 of ether.

Cinchocaine Hydrochloride

Synonyms. Percainum; Sovcainum.

Proprietary Names. Cincaim; Nupercaine.

$C_{20}H_{29}N_3O_2 \cdot HCl = 379.9$

CAS—61-12-1

Fine, white, hygroscopic, crystals or white crystalline powder. M.p. 95° to 100°.

Soluble 1 in 0.5 of water; freely soluble in ethanol and acetone; soluble in chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 7.5 (20°).

Colour Test. Mercurous Nitrate—black.

Thin-layer Chromatography. System TA—Rf 63; system TB—Rf 25; system TC—Rf 34; system TL—Rf 35. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2701.

High Pressure Liquid Chromatography. System HA— k' 1.9; system HR— k' 5.51.

Ultraviolet Spectrum. Aqueous acid—247 nm ($A_1^1 = 720$ a), 319 nm ($A_1^1 = 260$ a); aqueous alkali—238 nm, 325 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1598, 1643, 1540, 766, 1236, 1574 (KBr disk).

Mass Spectrum. Principal peaks at m/z 86, 87, 58, 149, 111, 99, 57, 41 (no peaks above 210).

Quantification. GAS CHROMATOGRAPHY-MASS SPECTROMETRY. In serum: sensitivity 1 ng/ml—D. Alkalay *et al.*, *Analyt. Lett. (Part B)*, 1981, 14, 1745–1756.

Disposition in the Body.

TOXICITY. Cinchocaine is more toxic than procaine by injection, and more toxic than cocaine by local application.

In a fatality involving the ingestion of cinchocaine, the following postmortem tissue concentrations were reported: blood 0.6 μg/ml, kidney 5.7 μg/g, liver 25 μg/g; ethanol was also detected in blood at a concentration of 1500 μg/ml (T. Borkowski and W. Gubala, *Bull. int. Ass. forens. Toxicol.*, 1976, 12(3), 18).

HALF-LIFE. Plasma half-life, about 11 hours.

Use. Cinchocaine is used in concentrations of 0.1 to 2% for surface anaesthesia.

Cinchonidine

Antimalarial

(8*S*,9*R*)-Cinchonan-9-ol

$C_{19}H_{22}N_2O = 294.4$

CAS—485-71-2

An alkaloid present in the bark of various species of *Cinchona* (Rubiaceae). Cinchonidine is the (–)-stereoisomer of cinchonine; quinine is its (–)-6'-methoxy derivative.

White crystals or powder. M.p. about 210°, with decomposition. Slightly soluble in water and ether; soluble 1 in 10 of ethanol.

Cinchonidine Sulphate

$(C_{19}H_{22}N_2O)_2 \cdot H_2SO_4 \cdot 7H_2O = 813.0$

CAS—524-61-8 (anhydrous)

Colourless, shining, silky crystals. M.p. about 207° (anhydrous salt).

Soluble 1 in 100 of water and 1 in 60 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 4.0, 8.2 (25°).

Thin-layer Chromatography. System TA—Rf 49; system TB—Rf 06; system TC—Rf 10. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2590.

High Pressure Liquid Chromatography. System HA— k' 3.1.

Ultraviolet Spectrum. Aqueous acid—236 nm ($A_1^1 = 1208$ a), 316 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 754, 899, 1090, 800, 877, 1587 (KBr disk).

Mass Spectrum. Principal peaks at m/z 136, 81, 137, 42, 41, 55, 130, 128.

Disposition in the Body. Metabolised by 2'-hydroxylation of the quinoline nucleus followed by 2-hydroxylation of the quinuclidine ring; both 2'-hydroxycinchonidine and 2,2'-dihydroxycinchonidine have been detected in urine.

Dose. Cinchonidine sulphate was formerly given in doses of 60 to 600 mg.

Cinchonine

Antimalarial

(8*R*,9*S*)-Cinchonan-9-ol

$C_{19}H_{22}N_2O = 294.4$

CAS—118-10-5

An alkaloid present in the bark of various species of *Cinchona* (Rubiaceae). Cinchonine is the (+)-stereoisomer of cinchonidine; quinidine is its (+)-6'-methoxy derivative.

White shining prisms or needles. M.p. 264°, subliming at 220°. Practically **insoluble** in water; slightly soluble in ethanol, chloroform, and ether.

Cinchonine Hydrochloride

$C_{19}H_{22}N_2O \cdot HCl \cdot 2H_2O = 366.9$

CAS—5949-11-1 (anhydrous)

White microcrystalline flakes or needles. M.p. about 215°, with decomposition (anhydrous salt).

Soluble 1 in 20 of water, 1 in 2 of ethanol, and 1 in 300 of ether.

Dissociation Constant. pK_a 4.1, 8.2 (25°).

Thin-layer Chromatography. System TA—Rf 49; system TB—Rf 06; system TC—Rf 10. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2590.

Ultraviolet Spectrum. Aqueous acid—235 nm ($A_1^1 = 1208$ a), 315 nm; aqueous alkali—288 nm, 302 nm, 315 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 760, 1110, 1505, 1590, 990, 909 (KBr disk).

Mass Spectrum. Principal peaks at m/z 136, 294, 81, 159, 55, 42, 41, 143.

Disposition in the Body. Rapidly and almost completely absorbed from the gastro-intestinal tract, peak plasma concentrations being attained in 1 to 2 hours. Metabolised by 2'-hydroxylation of the quinoline nucleus followed by 2-hydroxylation of the quinuclidine ring. About 55% of a dose is excreted as 2'-hydroxycinchonine, 22% as 2,2'-dihydroxycinchonine, and 5% as unchanged cinchonine.

Dose. Cinchonine hydrochloride was formerly given in doses of 60 to 600 mg.

Cinchophen

Analgesic

Synonyms. Acifenokinolin; Phenylcinchoninic Acid; Quinophan.

2-Phenylquinoline-4-carboxylic acid

$C_{16}H_{11}NO_2 = 249.3$

CAS—132-60-5

White or yellowish crystals or powder. M.p. 213° to 216°.

Practically **insoluble** in water; soluble 1 in 120 of ethanol, 1 in 40 of acetone, 1 in 400 of chloroform, and 1 in 100 of ether.

Colour Tests. Liebermann's Test—red-orange; Marquis Test—yellow; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 75. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—not eluted.

Ultraviolet Spectrum. Aqueous acid—243 nm ($A_1^1 = 610$ b), 268 nm, 344 nm; aqueous alkali—259 nm, 330 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 759, 1250, 1698, 699, 731, 1199 (KBr disk).

Disposition in the Body. Readily absorbed after oral administration and extensively metabolised; less than 5% of a dose is excreted in the urine unchanged.

HALF-LIFE. Plasma half-life, about 4 hours.

Dose. Cinchophen was formerly given in doses of 300 to 600 mg.

Cineole

Essential Oil

Synonyms. Cajuputol; Eucalyptol.

1,8-Epoxy-*p*-menthane

$C_{10}H_{18}O = 154.3$

CAS—470-82-6

Cineole is obtained from eucalyptus oil, cajuput oil, and other oils.

A colourless liquid with an aromatic camphoraceous odour. Wt per ml 0.922 to 0.924 g. F.p. not lower than 0°. B.p. about 175°.

Refractive index, at 20°, 1.456 to 1.460.

Practically **insoluble** in water; miscible with ethanol, chloroform, ether, and glacial acetic acid.

Infra-red Spectrum. Principal peaks at wavenumbers 980, 1075, 1219, 847, 1162, 1052.

Cinnarizine

Antihistamine

Proprietary Names. Cerepar; Cinnacet; Gigantēn; Midronal; Stugerol.

1-Benzhydryl-4-cinnamylpiperazine

$C_{26}H_{28}N_2 = 368.5$

CAS—298-57-7

Practically **insoluble** in water; soluble in dilute hydrochloric acid.

Thin-layer Chromatography. System TA—Rf 76; system TB—Rf 51; system TC—Rf 78. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 3065.

High Pressure Liquid Chromatography. System HA—k' 0.8.

Ultraviolet Spectrum. Aqueous acid—254 nm ($A_1^1 = 584$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 702, 691, 1138, 964, 740, 1000 (KBr disk).

Mass Spectrum. Principal peaks at m/z 201, 117, 167, 202, 251, 165, 118, 115.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 500 pg/ml, AFID—R. Woestenborghs *et al.*, *J. Chromat.*, 1982, 232; *Biomed. Appl.*, 21, 85–91.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 20 ng/ml, UV detection—V. Nitsche and H. Mascher, *J. Chromat.*, 1982, 227; *Biomed. Appl.*, 16, 521–524.

Disposition in the Body.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 50 mg to 6 subjects, a mean peak plasma concentration of 0.08 µg/ml was attained in 2.3 hours (H. K. L. Hundt *et al.*, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 378–382).

HALF-LIFE. Plasma half-life, about 5 hours.

Dose. Usually 45 to 90 mg daily; doses of 150 to 225 mg daily are given in peripheral arterial disease.

Cleflamide

Anti-amoebic

Synonym. Chlorophenoxamide

2,2 - Dichloro - N - (2 - hydroxyethyl) - N - [4 - (4 - nitrophenoxy)benzyl]acetamide

$C_{17}H_{16}Cl_2N_2O_5 = 399.2$

CAS—3576-64-5

A lemon-yellow crystalline powder. M.p. 134° to 137°.

Practically **insoluble** in water; soluble 1 in 100 of ethanol, 1 in 40 of acetone, and 1 in 80 of chloroform.

Colour Tests. Mandelin's Test—green → brown; Marquis Test—yellow; Sulphuric Acid—yellow.

Thin-layer Chromatography. System TA—Rf 69; system TB—Rf 00; system TC—Rf 56. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Ethanol—303 nm ($A_1^1 = 310$ b). (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 1244, 1666, 1510, 1595, 1078, 880 (KBr disk).

Mass Spectrum. Principal peaks at m/z 228, 182, 363, 88, 229, 76, 276, 257.

Disposition in the Body. Poorly absorbed after oral administration.

Dose. Cleflamide has been given in doses of 1.5 to 2.25 g daily.

Clemastine

Antihistamine

Synonyms. Meclostine; Mecloprodin.

(+)-(2*R*)-2-{2-[(*R*)-4-Chloro- α -methylbenzhydryloxy]ethyl}-1-methylpyrrolidine

$C_{21}H_{26}ClNO = 343.9$

CAS—15686-51-8

Soluble in chloroform.

Clemastine Fumarate

Proprietary Names. Aller-eze; Tavegil; Tavegil; Tavist.

$C_{21}H_{26}ClNO \cdot C_4H_4O_4 = 460.0$

CAS—14976-57-9

A white crystalline powder.

Slightly **soluble** in dilute acetic acid; soluble in methanol.

Colour Tests. Liebermann's Test—brown; Mandelin's Test—yellow-brown; Marquis Test—yellow (green rim); Sulphuric Acid—yellow (green rim).

Thin-layer Chromatography. System *TA*—Rf 46; system *TB*—Rf 48; system *TC*—Rf 25. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2415; system *GF*—RI 2710.

High Pressure Liquid Chromatography. System *HA*— k' 3.7.

Ultraviolet Spectrum. Aqueous acid—257 nm ($A_1^1 = 27$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1090, 1011, 700, 763, 1121, 1210 (KBr disk).

Mass Spectrum. Principal peaks at m/z 84, 128, 179, 42, 85, 178, 214, 98.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 1 ng/ml, ECD—R. Tham *et al.*, *Arzneimittel-Forsch.*, 1978, 28, 1017–1020.

Disposition in the Body.

THERAPEUTIC CONCENTRATION.

Following a single oral dose equivalent to 2 mg of clemastine to 12 subjects, peak plasma concentrations of about 0.002 μ g/ml were attained in 3 to 5 hours (R. Tham *et al.*, *ibid.*).

Dose. The equivalent of 2 to 6 mg of clemastine daily.

Clemizole

Antihistamine

1-(4-Chlorobenzyl)-2-(pyrrolidin-1-ylmethyl)benzimidazole

$C_{19}H_{20}ClN_3 = 325.8$

CAS—442-52-4

Crystals. M.p. 167°.

Clemizole Hydrochloride

Proprietary Name. Allercur

$C_{19}H_{20}ClN_3 \cdot HCl = 362.3$

CAS—1163-36-6

A white crystalline powder. M.p. about 246°.

Sparingly **soluble** in water; soluble in ethanol and chloroform; practically insoluble in ether.

Thin-layer Chromatography. System *TA*—Rf 78; system *TB*—Rf 31; system *TC*—Rf 69. (Dragendorff spray, positive; acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2675.

High Pressure Liquid Chromatography. System *HA*— k' 4.8 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—275 nm ($A_1^1 = 330$ a); aqueous alkali—254 nm ($A_1^1 = 253$ b), 269 nm, 275 nm, 283 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 748, 765, 740, 833, 1111, 1010 (KBr disk).

Mass Spectrum. Principal peaks at m/z 131, 256, 125, 42, 255, 89, 258, 257.

Dose. 40 to 160 mg of clemizole hydrochloride daily.

Clidinium Bromide

Anticholinergic

Proprietary Names. Quarzan. It is an ingredient of Librax(in).

3-Benzoyloxy-1-methylquinuclidinium bromide

$C_{22}H_{26}BrNO_3 = 432.4$

CAS—7020-55-5 (clidinium); 3485-62-9 (bromide)

A white crystalline powder. M.p. about 242°.

Soluble in water and ethanol; slightly soluble in ether.

Colour Tests. The following tests are performed on the nitrate (see p. 128): Liebermann's Test—orange → brown; Mandelin's Test—brown; Marquis Test—orange → blue; Sulphuric Acid—orange.

Thin-layer Chromatography. System TA—Rf 02. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—253 nm ($A_1^1 = 10$ b), 259 nm ($A_1^1 = 11$ b); methanol—252 nm, 258 nm ($A_1^1 = 10.4$ a), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1730, 1240, 769, 1190, 712, 1011.

Mass Spectrum. Principal peaks at m/z 105, 77, 96, 183, 51, 42, 182, 94.

Disposition in the Body. The major metabolite is 3-hydroxy-1-methylquinuclidinium bromide.

Dose. 7.5 to 20 mg daily.

Clindamycin

Antibiotic

Synonyms. Chlorodeoxylincomycin; (7*S*)-Chloro-7-deoxylincomycin.

Note. The name Clinimycin was formerly used for clindamycin and has also been used for a preparation of oxytetracycline.

Methyl 6-amino-7-chloro-6,7,8-trideoxy-*N*-[(2*S*,4*R*)-1-methyl-4-propylpropyl]-1-thio-β-*L*-threo-*D*-galacto-octopyranoside

$C_{18}H_{33}ClN_2O_5S = 425.0$

CAS—18323-44-9

A yellow, amorphous solid.

Clindamycin Hydrochloride

Proprietary Names. Cleocin; Dalacin C; Dalacin(e); Sobelin (all as capsules).

$C_{18}H_{33}ClN_2O_5S \cdot HCl \cdot H_2O = 479.5$

CAS—21462-39-5 (anhydrous); 58207-19-5 (monohydrate)

A white crystalline powder. M.p. 141° to 143°.

Soluble 1 in 2 of water and 1 in 200 of ethanol; freely soluble in methanol; very slightly soluble in chloroform.

Clindamycin Palmitate Hydrochloride

Proprietary Names. Cleocin; Dalacin; Dalacin C; Sobelin (all as granules for oral suspension).

$C_{34}H_{63}ClN_2O_6S \cdot HCl = 699.9$

CAS—36688-78-5 (palmitate); 25507-04-4 (palmitate hydrochloride)

A white amorphous powder. It hydrolyses in solutions above pH 6.0.

Freely **soluble** in water, ethanol, chloroform, and ether.

Clindamycin Phosphate

Proprietary Names. Cleocin; Dalacin; Dalacin C; Sobelin (all as injection).

$C_{18}H_{34}ClN_2O_8PS = 505.0$

CAS—24729-96-2

A white, hygroscopic, crystalline powder.

Soluble 1 in 2.5 of water; slightly soluble in dehydrated alcohol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 7.7 (25°).

Colour Tests. Palladium Chloride—yellow; Sodium Nitroprusside (Method 2)—violet.

Thin-layer Chromatography. *System TA*—Rf 72. (*Acidified iodoplatinate solution*, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1513, 1664, 1080, 1050, 1302, 1250 (KBr disk).

Dose. The equivalent of 0.6 to 1.8 g of clindamycin daily.

Clioquinol

Anti-amoebic

Synonyms. Chinoform; Chloriodoquine; Clioquinolium; Iodo-chlorhydroxyquin; Iodochlorhydroxyquinoline; Quiniiodochlor; Vioform.

Proprietary Names. Budoform; Entero-Valodon; Entero-Vioform; Vioform. It is an ingredient of Oralcer and Unidiarea.

5-Chloro-7-iodoquinolin-8-ol

$C_9H_5ClINO = 305.5$

CAS—130-26-7

A yellowish-white to brownish-yellow, voluminous powder. It darkens on exposure to light. M.p. about 180°, with decomposition.

Practically **insoluble** in water and ethanol; soluble 1 in 43 of boiling ethanol and 1 in about 120 of chloroform; soluble in dimethylformamide; very slightly soluble in ether.

Thin-layer Chromatography. *System TA*—Rf 56; *system TB*—Rf 00; *system TC*—Rf 05.

Ultraviolet Spectrum. Methanol—255 nm ($A_1^1 = 1196$ a), 325 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 953, 1198, 808, 784, 1266, 728 (KBr disk).

Mass Spectrum. Principal peaks at m/z 305, 150, 307, 115, 152, 114, 306, 123.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 50 ng/ml, ECD—A. Sioufi and F. Pommier, *J. Chromat.*, 1981, 226; *Biomed. Appl.*, 15, 219–223.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: detection limit 600 ng/ml, UV detection—K. Hayakawa *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 159–165.

Disposition in the Body. Poorly absorbed after oral administration. About 25% of a dose is excreted in the urine in 24 hours as glucuronide and sulphate conjugates.

**THERAPEUTIC CONCENTRATION.**

Following single oral doses of 250 and 1500 mg to 6 subjects, peak plasma concentrations of 1.7 to 8.3 μg/ml (mean 5.2) and 14.6 to 34.8 μg/ml (mean 23), respectively, were attained in 2 to 4 hours (D. B. Jack and W. Riess, *J. pharm. Sci.*, 1973, 62, 1929–1932).

HALF-LIFE. Plasma half-life, 11 to 14 hours.

REFERENCE. D. B. Jack and W. Riess, *ibid.*

Dose. Usually 0.75 to 1.5 g daily.

Clioquinol

Anthelmintic (Veterinary)

2-(4-Chlorophenylcarbamoyl)-4,6-di-iodophenyl acetate

$C_{15}H_{10}ClI_2NO_3 = 541.5$

CAS—14437-41-3

A white crystalline powder. M.p. 215° to 216°. Sparingly **soluble** in water; moderately soluble in ethanol and acetone; soluble in chloroform.

Colour Tests. Iodine Test—positive; Mandelin's Test—red-brown.

Thin-layer Chromatography. System TA—Rf 79. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—not eluted.

Ultraviolet Spectrum. Ethanol—233 nm ($A_1^1 = 625$ b); aqueous alkali—240 nm ($A_1^1 = 561$ b), 282 nm ($A_1^1 = 270$ b), 362 nm ($A_1^1 = 172$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1190, 1647, 1520, 1309, 1764, 816 (Nujol mull).

Clobazam

Tranquilliser

Proprietary Names. Frisium; Urbadan; Urbanyl.

7 - Chloro - 1 - methyl - 5 - phenyl - 1*H* - 1,5 - benzodiazepine - 2,4(3*H*,5*H*)-dione

$C_{16}H_{13}ClN_2O_2 = 300.7$

CAS—22316-47-8

Crystals. M.p. 180° to 182°.

Practically **insoluble** in water; sparingly soluble in ethanol; freely soluble in acetone and chloroform.

Colour Test. Aromaticity (Method 2)—colourless (heat for 3 min)/red.

Thin-layer Chromatography. System TA—Rf 62; system TB—Rf 09; system TC—Rf 70; system TD—Rf 53; system TE—Rf 73; system TF—Rf 49.

Gas Chromatography. System GA—clobazam RI 2694, desmethylclobazam RI 2755; system GG—RI 3147.

High Pressure Liquid Chromatography. System HI—clobazam k' 3.91, desmethylclobazam k' 3.06; system HK—clobazam k' 0.03, desmethylclobazam k' 0.01.

Ultraviolet Spectrum. Aqueous acid—230 nm ($A_1^1 = 1373$ b), 289 nm ($A_1^1 = 76$ b); aqueous alkali—286 nm ($A_1^1 = 193$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1684, 1664, 704, 1490, 764, 845 (KBr disk).

Mass Spectrum. Principal peaks at m/z 300, 258, 77, 259, 283, 302, 231, 256; desmethylclobazam 286, 244, 77, 218, 51, 217, 288, 215.

Quantification. GAS CHROMATOGRAPHY. In plasma: limits of detection 3 ng/ml for clobazam and 5 ng/ml for desmethylclobazam, ECD—D. J. Greenblatt, *J. pharm. Sci.*, 1980, 69, 1351–1352.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 50 ng/ml for clobazam and 100 ng/ml for desmethylclobazam, UV detection—A. Brachet-Liermain *et al.*, *Ther. Drug Monit.*, 1982, 4, 301–305.

Disposition in the Body. Readily absorbed after oral administration. Metabolites found in the serum include desmethylclobazam, which is thought to be active, 4'-hydroxyclobazam, and 4'-hydroxydesmethylclobazam. About 90% of a dose is excreted in the urine in 17 days and about 2% is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 20 mg, administered to 16 subjects, peak serum concentrations of 0.30 to 0.95 µg/ml (mean 0.57) were attained in about 1.3 hours (H. R. Ochs *et al.*, *Eur. J. clin. Pharmac.*, 1984, 26, 499–503).

Following daily oral doses of 10 mg to 7 young male and 6 elderly male subjects, the mean steady-state plasma concentrations for the two groups were: clobazam 0.12 to 0.25 µg/ml (mean 0.17) and 0.17 to 0.41 µg/ml (mean 0.3); desmethylclobazam 0.12 to 0.25 µg/ml (mean 0.16) and 0.21 to 12.8 µg/ml (mean 3.9), respectively. The corresponding steady-state

plasma concentrations in 5 young female and 6 elderly female subjects, receiving the same dosage schedule, were: clobazam 0.19 to 0.27 µg/ml (mean 0.23) and 0.16 to 0.32 µg/ml (mean 0.23); desmethylclobazam 0.22 to 1.37 µg/ml (mean 0.7) and 0.17 to 4.13 µg/ml (mean 1.0), respectively (D. J. Greenblatt *et al.*, *Clin. Pharmacokinet.*, 1983, 8, 83-94).

TOXICITY. Up to 300 mg has been ingested without serious toxic effects.

HALF-LIFE. Plasma half-life, clobazam 10 to 58 hours (mean 25), desmethylclobazam, about 40 hours. The half-life may be prolonged considerably in elderly subjects.

VOLUME OF DISTRIBUTION. About 1 litre/kg.

CLEARANCE. Plasma clearance, about 0.5 ml/min/kg.

PROTEIN BINDING. In plasma, about 85%.

NOTE. For a review of the pharmacokinetics of clobazam see R. N. Brogden *et al.*, *Drugs*, 1980, 20, 161-178.

Dose. 20 to 60 mg daily.

Clobetasol Propionate

Corticosteroid

Proprietary Names. Dermoval; Dermovat(e); Dermoxin.

21-Chloro-9α-fluoro-11β,17α-dihydroxy-16β-methylpregna-1,4-diene-3,20-dione 17-propionate

$C_{25}H_{32}ClFO_5 = 467.0$

CAS—25122-41-2 (clobetasol); 25122-46-7 (propionate)

A white to creamy-white, crystalline powder. M.p. about 195°. Practically **insoluble** in water; soluble 1 in 100 of ethanol and 1 in 1000 of ether; soluble in acetone and chloroform.

Ultraviolet Spectrum. Methanol—239 nm ($A_1^1 = 390$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1666, 1612, 1724, 884, 1063, 1010.

Use. Topically in a concentration of 0.05%.

Clobetasone Butyrate

Corticosteroid

Proprietary Names. Emovat(e); Eumovate. It is an ingredient of Trimovate.

21-Chloro-9α-fluoro-17α-hydroxy-16β-methylpregna-1,4-diene-3,11,20-trione 17-butyrate

$C_{26}H_{32}ClFO_5 = 479.0$

CAS—54063-32-0 (clobetasone); 25122-57-0 (butyrate)

A white crystalline powder. M.p. 90° to 100°.

Practically **insoluble** in water; soluble in many organic solvents.

Ultraviolet Spectrum. Methanol—236 nm ($A_1^1 = 330$ b).

Mass Spectrum. Principal peaks at m/z 331, 43, 71, 332, 121, 147, 131, 41 (clobetasone).

Use. Topically in a concentration of 0.05%.

Clofazimine

Antileprotic

Synonym. Riminophenazine

Proprietary Name. Lampren(e)

3-(4-Chloroanilino)-10-(4-chlorophenyl)-2,10-dihydro-2-phenazin-2-ylideneisopropylamine

$C_{27}H_{22}Cl_2N_4 = 473.4$

CAS—2030-63-9

Dark red crystals or orange-red microcrystalline powder. M.p. about 215°.

Practically **insoluble** in water; soluble 1 in 700 of ethanol, 1 in 15 of chloroform, and 1 in 1000 of ether; soluble in dilute acetic acid and dimethylformamide.

Colour Tests. Mandelin's Test—yellow-brown; Marquis Test—violet; Sulphuric Acid—violet.

Thin-layer Chromatography. *System TA*—Rf 70; *system TB*—Rf 57; *system TC*—Rf 59. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—not eluted.

Ultraviolet Spectrum. Methanolic acid—283 nm ($A_1^1 = 1300$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1508, 1560, 1295, 1587, 747, 1083 (KBr disk).

Mass Spectrum. Principal peaks at m/z 455, 457, 472, 474, 459, 456, 458, 473.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, UV detection—J. H. Peters *et al.*, *J. Chromat.*, 1982, 229; *Biomed. Appl.*, 18, 503-508.

THIN-LAYER CHROMATOGRAPHY. In plasma: detection limit 5 ng/ml—Z. Lanyi and J. P. Dubois, *J. Chromat.*, 1982, 232; *Biomed. Appl.*, 21, 219-223.

Disposition in the Body. Incompletely absorbed after oral administration. It is stored in body tissues and only very slowly

A clear, colourless to pale yellow liquid. Wt per ml 1.138 to 1.144 g. Practically **immiscible** with water; readily miscible with ethanol, chloroform, and ether.

Dissociation Constant. pK_a 3.0 (clofibric acid).

Colour Tests. Liebermann's Test—violet-brown; Marquis Test—blue (deepening).

Thin-layer Chromatography. System TD—Rf 75; system TE—Rf 82; system TF—Rf 66.

Gas Chromatography. System GA—RI 1549.

Ultraviolet Spectrum. Dehydrated alcohol—280 nm ($A_1^1 = 43$ b), 288 nm ($A_1^1 = 31$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1140, 1238, 1735, 1175, 1282, 1090 (KBr disk).

excreted in the urine. 3-(*p*-Hydroxy)clofazimine and a 3-glucuronide conjugate have been detected in the urine, each accounting for less than 0.5% of a daily dose.

THERAPEUTIC CONCENTRATION.

Following single oral doses of 200 mg and 400 mg to 1 subject, peak plasma concentrations of 0.07 µg/ml and 0.16 µg/ml were attained in 8 and 4 hours respectively; plasma concentrations of clofazimine were still detectable at 264 hours (Z. Lanyi and J. P. Dubois, *ibid.*).

Dose. 50 to 100 mg daily; 300 mg daily for lepra reactions.

Clofibrate

Lipid Regulating Agent

Synonyms. Ethyl Chlorophenoxyisobutyrate; Ethyl Clofibrate.

Proprietary Names. Amotril; Atheropront; Atromidin; Atromid-S; Azionyl; Claripex; Clofibral; Clofirem; Lipavlon; Liprin(al); Normolipol; Novofibrate; Regelan; Skleromexe.

Ethyl 2-(4-chlorophenoxy)-2-methylpropionate

$C_{12}H_{15}ClO_3 = 242.7$

CAS—637-07-0

Mass Spectrum. Principal peaks at m/z 128, 130, 169, 87, 41, 129, 242, 171.

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 1 µg/ml for clofibrate and clofibric acid, FID—M. S. Wolf and J. J. Zimmerman, *J. pharm. Sci.*, 1980, 69, 92–93.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma, saliva or urine: sensitivity 500 ng/ml for clofibric acid, UV detection—T. D. Bjornsson *et al.*, *J. Chromat.*, 1977, 137, 145–152. In plasma or urine: sensitivity 10 µg/ml for clofibric acid and 1.5 µg/ml for the glucuronide, UV detection—J. R. Veenendaal and P. J. Meffin, *J. Chromat.*, 1981, 223; *Biomed. Appl.*, 12, 147–154.

Disposition in the Body. Readily and almost completely absorbed after oral administration. Rapidly hydrolysed by serum enzymes to clofibric acid, 2-(4-chlorophenoxy)-2-methylpropionic acid (active), which is conjugated with glucuronic acid. About 50 to 85% of a dose is excreted in the urine in 48 hours mostly as conjugated clofibric acid.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 1 g, given to 8 subjects, peak plasma concentrations of 43 to 79 µg/ml (mean 55) of clofibric acid were attained in 2 to 8 hours (L. F. Chasseaud *et al.*, *J. clin. Pharmac.*, 1974, 14, 382–386).

After a single oral dose of 2 g, given to 5 subjects, a mean plasma concentration of 151 µg/ml of clofibric acid was attained in 4 to 6 hours; a mean steady-state plasma concentration of 122 µg/ml of clofibric acid was achieved after administering 1 g twice daily to 5 subjects (R. Gugler, *Clin. Pharmac. Ther.*, 1978, 24, 432–438).

TOXICITY.

A 15-year-old boy who took 24.5 g of clofibrate in a suicide attempt complained of headache, pain in the arms, and inability to walk, but no evidence of toxicity was found in the following 5 days (A. H. Greenhouse, *J. Am. med. Ass.*, 1968, 204, 402–403).

HALF-LIFE. Plasma half-life, clofibric acid 12 to 25 hours but may be decreased when free fatty acid concentrations are high; longer half-lives have been reported after repeated doses, and in subjects with renal impairment.

VOLUME OF DISTRIBUTION. Clofibric acid, about 0.1 to 0.2 litre/kg.

PROTEIN BINDING. In plasma, clofibric acid, about 95 to 98%. This may be reduced in the presence of high free fatty acid concentrations and is progressively reduced at plasma concentrations greater than 50 µg/ml.

NOTE. For a summary of the clinical pharmacokinetics of clofibrate see L. B. Sheiner *et al.*, *J. Pharmacokinetic. Biopharm.*, 1981, 9, 84–87.

Dose. 20 to 30 mg/kg daily, by mouth.

Clomiphene*Induction of Ovulation*

Synonyms. Chloramiphene; Clomifene.

A mixture of the *E* and *Z* isomers of 2-[4-(2-Chloro-1,2-diphenylvinyl)phenoxy]triethylamine.

Clomiphene may be separated into its *E* and *Z* isomers, enclomiphene and zuclophene.

$C_{26}H_{28}ClNO = 406.0$

CAS—911-45-5; 15690-57-0 (*E*); 15690-55-8 (*Z*)

A white to pale yellow solid. M.p. 111° to 115°.

Sparingly **soluble** in water and ethanol; slightly soluble in chloroform.

Clomiphene Citrate

Proprietary Names. Clomid; Clomivid; Dyneric; Serophene.

$C_{26}H_{28}ClNO \cdot C_6H_8O_7 = 598.1$

CAS—50-41-9; 7599-79-3 (*E*); 7619-53-6 (*Z*)

A white to pale yellow powder. M.p. about 145°, with decomposition.

Soluble 1 in 900 of water, 1 in 40 of ethanol, and 1 in 800 of chloroform; freely soluble in glacial acetic acid and methanol; practically insoluble in ether.

Colour Tests. Liebermann's Test—brown; Mandelin's Test—violet → orange-brown; Marquis Test—violet-brown.

Thin-layer Chromatography. System *TA*—Rf 60; system *TB*—Rf 56; system *TC*—Rf 52. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2930.

Ultraviolet Spectrum. Aqueous acid—235 nm ($A_1^1 = 464$ b), 292 nm ($A_1^1 = 259$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1590, 1111, 1245, 1505, 700, 1170.

Mass Spectrum. Principal peaks at *m/z* 86, 87, 100, 30, 58, 44, 42, 29.

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit 350 pg/ml, photolysis and fluorescence detection—P. J. Harman *et al.*, *J. Chromat.*, 1981, 225; *Biomed. Appl.*, 14, 131–138.

Disposition in the Body. Absorbed after oral administration and slowly excreted in the bile; enterohepatic circulation occurs.

HALF-LIFE. Biological half-life, about 5 days.

Dose. 50 mg of clomiphene citrate daily, for 5 days; up to 250 mg daily has been given.

Clomipramine

Antidepressant

Synonyms. Chlorimipramine; Monochlorimipramine.3-(3-Chloro-10,11-dihydro-5H-dibenz[*b,f*]azepin-5-yl)-*NN*-dimethylpropylamine $C_{19}H_{23}ClN_2 = 314.9$

CAS—303-49-1

**Clomipramine Hydrochloride***Proprietary Name.* Anafranil $C_{19}H_{23}ClN_2 \cdot HCl = 351.3$

CAS—17321-77-6

A white or slightly yellow crystalline powder. M.p. about 192°.

Soluble 1 in 8 of water, 1 in 5 of ethanol, 1 in 3 of chloroform, and 1 in 100 of ether.**Partition Coefficient.** Log *P* (octanol/pH 7.4), 3.3.**Colour Tests.** Forrest Reagent—blue; FPN Reagent—blue; Liebermann's Test—blue; Mandelin's Test—blue.**Thin-layer Chromatography.** System *TA*—Rf 51; system *TB*—Rf 54; system *TC*—Rf 34. (Acidified iodoplatinate solution, strong reaction.)**Gas Chromatography.** System *GA*—RI 2406; system *GF*—RI 2795.**High Pressure Liquid Chromatography.** System *HA*—clomipramine *k'* 3.4, monodesmethylclomipramine *k'* 2.0; system *HF*—*k'* 9.92.**Ultraviolet Spectrum.** Aqueous acid—251 nm ($A_1^1 = 253$ a).**Infra-red Spectrum.** Principal peaks at wavenumbers 752, 1225, 805, 842, 1212, 1237 (clomipramine hydrochloride, KBr disk).**Mass Spectrum.** Principal peaks at *m/z* 58, 85, 269, 268, 270, 271, 314, 242; monodesmethylclomipramine 44, 71, 268, 227, 193, 42, 269, 229; 8-hydroxyclopmipramine 58, 85, 86, 57, 84, 70, 43, 268.**Quantification.** GAS CHROMATOGRAPHY. In plasma: detection limit 5 ng, AFID—L. Gifford *et al.*, *J. Chromat.*, 1975, 105, 107–113.HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or blood: sensitivity 5-ng/ml for clomipramine and 10 ng/ml for monodesmethylclomipramine, UV detection—J. Godbillon and S. Gauron, *J. Chromat.*, 1981, 204, 303–311.RADIOIMMUNOASSAY. In plasma: sensitivity 200 pg/ml—G. F. Read and D. Riad-Fahmy, *Clin. Chem.*, 1978, 24, 36–40.REVIEW. For a review of analytical methods see B. A. Scoggins *et al.*, *Clin. Chem.*, 1980, 26, 5–17.**Disposition in the Body.** Rapidly and completely absorbed after oral administration, but undergoes extensive first-pass *N*-demethylation to the major active metabolite, monodesmethylclomipramine. Clomipramine and monodesmethylclomipramine are further metabolised by 8-hydroxylation, *N*-oxidation, and conjugation. About 10 to 15% of a dose is excreted in the urine in 24 hours, of which less than 0.2% is unchanged clomipramine or monodesmethylclomipramine. A total of 45 to 60% of a dose is excreted in the urine over a period of 14 days and about 20 to 30% is slowly eliminated in the faeces.**THERAPEUTIC CONCENTRATION.** Plasma concentrations of clomipramine and the desmethyl metabolite vary considerably between individual patients. Steady-state concentrations of clomipramine are usually achieved in about 1 to 2 weeks, but monodesmethylclomipramine may continue to accumulate for 6 weeks or longer. 8-Hydroxyclopmipramine and 8-hydroxydesmethylclomipramine have been detected in plasma at significant concentrations during high-dose chronic treatment.After a single oral dose of 50 mg, given to 5 subjects, peak plasma concentrations of clomipramine of 0.02 to 0.07 µg/ml (mean 0.05) were attained in 2 to 4 hours; peak plasma concentrations of monodesmethylclomipramine of 0.0005 to 0.012 µg/ml (mean 0.005) were attained in 4 to 24 hours (R. Jones and D. Luscombe, *Postgrad. med. J.*, 1976, 52, Suppl. 3, 62–67).Steady-state plasma concentrations of 0.10 to 0.48 µg/ml (mean 0.23) were reported after daily oral doses of 150 mg given to 17 subjects; the steady-state concentration of monodesmethylclomipramine was 0.24 to 0.96 µg/ml (mean 0.45) (S. Montgomery *et al.*, *Postgrad. med. J.*, 1980, 56, Suppl. 1, 130–133).**TOXICITY.** Toxic effects have been associated with blood concentrations greater than 0.4 µg/ml of clomipramine plus monodesmethylclomipramine.

In 2 fatalities due to clomipramine, postmortem concentrations were: blood 1 µg/ml, trace; brain —, 4.5 µg/g; liver 30, 22 µg/g; urine 25, — µg/ml (M. T. Haqqani and D. R. Gutteridge, *Forens. Sci.*, 1974, 3, 83–87).

In a fatality due to clomipramine overdose, the following postmortem concentrations were reported: blood, clomipramine 0.54 µg/ml and monodesmethylclomipramine 0.58 µg/ml; urine, clomipramine 0.35 µg/ml and monodesmethylclomipramine 0.70 µg/ml (R. C. Meatherall *et al.*, *J. analyt. Toxicol.*, 1983, 7, 168–171).

For details of a fatality involving the ingestion of clomipramine and trimipramine, see under Trimipramine.

HALF-LIFE. Plasma half-life, 20 to 84 hours (mean 36); decreased in children.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, 1.2.

PROTEIN BINDING. In plasma, clomipramine 90 to 95%, monodesmethylclomipramine 97 to 99%.

NOTE. For a review of the pharmacokinetics of tricyclic antidepressants see G. Molnar and R. N. Gupta, *Biopharm. Drug Disp.*, 1980, 1, 283–305.

Dose. 10 to 150 mg of clomipramine hydrochloride daily.

Clomocycline

Antibiotic

Synonyms. Chlormethylencycline; *N*²-(Hydroxymethyl)chlortetracycline; Methylolchlortetracycline.

7-Chloro-*N*²-(hydroxymethyl)tetracycline

C₂₃H₂₅ClN₂O₉ = 508.9

CAS—1181-54-0

A yellow powder. It is sensitive to light and air, and undergoes decomposition between 145° and 170° without a definite melting point.

Clomocycline Sodium

Proprietary Name. Megaclor

C₂₃H₂₄ClN₂NaO₉ = 530.9

A yellow powder. It is sensitive to light and air, and undergoes decomposition without melting.

Very **soluble** in water; soluble 1 in 250 of ethanol; practically insoluble in chloroform and ether.

Colour Tests. Benedict's Reagent—red; Formaldehyde-Sulphuric Acid—orange-brown; Liebermann's Test—black; Mandelin's Test—violet→brown; Marquis Test—orange-brown; Sulphuric Acid—blue-black.

Thin-layer Chromatography. System *TA*—Rf 05, streaking. (Acidified potassium permanganate solution, strong reaction.)

Ultraviolet Spectrum. Aqueous acid—229 nm, 268 nm (*A*₁¹ = 350 b); aqueous alkali—251 nm, 283 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1600, 1634, 1501, 1307, 1205, 1235 (clomocycline sodium, KBr disk).

Dose. 0.68 to 1.36 g of clomocycline sodium daily.

Clonazepam

Anticonvulsant

Proprietary Names. Clonopin; Rivotril.

5-(2-Chlorophenyl)-1,3-dihydro-7-nitro-2*H*-1,4-benzodiazepin-2-one

C₁₅H₁₀ClN₃O₃ = 315.7

CAS—1622-61-3

A light yellow powder. M.p. about 239°.

Practically **insoluble** in water; slightly soluble in ethanol and ether; sparingly soluble in acetone and chloroform.

Dissociation Constant. p*K*_a 1.5, 10.5.

Partition Coefficient. Log *P* (octanol/pH 7.4), 2.4.

Colour Test. Formaldehyde-Sulphuric Acid—orange.

Thin-layer Chromatography. System *TA*—Rf 72; system *TB*—Rf 00; system *TC*—Rf 53; system *TD*—Rf 35; system *TE*—Rf 60; system *TF*—Rf 45. (Acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive.)

Gas Chromatography. System *GA*—clonazepam RI 2885, 7-acetamidoclonazepam RI 3263, 7-aminoclonazepam RI 2900, 7-amino-3-hydroxycloclonazepam RI 2890; system *GG*—RI 3600.

High Pressure Liquid Chromatography. System *HI*—*k'* 2.85; system *HK*—*k'* 0.35.

Ultraviolet Spectrum. Aqueous acid—273 nm (*A*₁¹ = 645 b); methanol—245 nm (*A*₁¹ = 460 b), 309 nm (*A*₁¹ = 360 b).

Infra-red Spectrum. Principal peaks at wavenumbers 1685, 1610, 748, 1255, 1578, 1532 (KBr disk).

Mass Spectrum. Principal peaks at m/z 280, 314, 315, 286, 234, 288, 316, 240; 7-acetamidoclonazepam 43, 327, 299, 298, 292, 329, 328, 256; 7-aminoclonazepam 285, 256, 257, 258, 44, 287, 110, 220.

Quantification. GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In plasma: detection limit 1 ng/ml, ECD—A. G. de Boer *et al.*, *J. Chromat.*, 1978, 145; *Biomed. Appl.*, 2, 105–114. In plasma: sensitivity 5 ng/ml, AFID—A. K. Dhar and H. Kutt, *J. Chromat.*, 1981, 222; *Biomed. Appl.*, 11, 203–211.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: clonazepam, 7-acetamidoclonazepam, and 7-aminoclonazepam, sensitivity 10 ng/ml, UV detection—I. Petters *et al.*, *J. Chromat.*, 1984, 306; *Biomed. Appl.*, 31, 241–248.

RADIOIMMUNOASSAY. In plasma: sensitivity 5 ng/ml—W. Dixon *et al.*, *J. pharm. Sci.*, 1977, 66, 235–237.

Disposition in the Body. Rapidly absorbed after oral administration; bioavailability greater than 80%. The major metabolic reaction is reduction of the nitro group to 7-aminoclonazepam,

followed by acetylation to 7-acetamidoclonazepam; 7-aminoclonazepam is slightly active and is found in plasma at concentrations similar to those of clonazepam. 3-Hydroxylation of clonazepam and its two metabolites may also occur, followed by conjugation with glucuronic acid or sulphate. Less than 1% of a dose is excreted unchanged in the urine in 24 hours. Urinary excretion accounts for up to 70% of a dose, as both free and conjugated metabolites, over a period of 7 days, of which about 50% consists of 7-aminoclonazepam and 7-acetamidoclonazepam.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 0.02 to 0.07 µg/ml.

A single oral dose of 2 mg given to 8 subjects produced peak plasma concentrations of 0.007 to 0.024 µg/ml (mean 0.017) in 1 to 4 hours (A. Berlin and H. Dahlström, *Eur. J. clin. Pharmac.*, 1975, 9, 155–159).

After daily oral dosing of 25 subjects with 6 mg per day, steady-state plasma concentrations of 0.029 to 0.075 µg/ml of clonazepam, 0.023 to 0.137 µg/ml of 7-aminoclonazepam, and <0.003 to 0.013 µg/ml of 7-acetamidoclonazepam were reported (J. Naestoft and N.-E. Larsen, *J. Chromat.*, 1974, 93, 113–122).

TOXICITY. Toxicity is associated with plasma concentrations greater than 0.1 µg/ml.

HALF-LIFE. Plasma half-life, 18 to 45 hours.

VOLUME OF DISTRIBUTION. About 2 to 4 litres/kg.

CLEARANCE. Plasma clearance, about 1 ml/min/kg.

PROTEIN BINDING. In plasma, about 85%.

NOTE. For a review of the pharmacokinetics of clonazepam, see R. M. Pinder *et al.*, *Drugs*, 1976, 12, 321–361.

Dose. 4 to 8 mg daily.

Clonidine

Antihypertensive

Synonym. Chlophazoline

2,6-Dichloro-*N*-(imidazolidin-2-ylidene)aniline

$C_9H_8Cl_2N_3$ = 230.1

CAS—4205-90-7

A white powder. M.p. 140° to 143°.

Soluble 1 in 8 of chloroform and 1 in 50 of ether.

Clonidine Hydrochloride

Proprietary Names. Catapres(an); Dixarit; Isoglaucan.

$C_9H_9Cl_2N_3 \cdot HCl$ = 266.6

CAS—4205-91-8

A white crystalline powder. M.p. about 313°.

Soluble 1 in 13 of water, 1 in 25 of ethanol, 1 in 38 of dehydrated alcohol, and 1 in 250 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 8.2.

Colour Test. Liebermann's Test—yellow (→ orange at 100°).

Thin-layer Chromatography. *System TA*—Rf 62; *system TB*—Rf 08; *system TC*—Rf 31. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 2248.

High Pressure Liquid Chromatography. *System HA*— k' 1.2.

Ultraviolet Spectrum. Aqueous acid—271 nm ($A_1^1 = 21$ a), 278 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1653, 1610, 778, 795, 1295, 1568 (clonidine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 229, 30, 231, 172, 194, 174, 200, 230.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 25 pg/ml in plasma, ECD—L.-C. Chu *et al.*, *J. pharm. Sci.*, 1979, 68, 72–74.

GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In plasma: sensitivity 100 pg/ml, ECD—P. O. Edlund, *J. Chromat.*, 1980, 187, 161–169.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma or urine: detection limit 100 pg/ml in plasma—S. Murray *et al.*, *Biomed. Mass Spectrom.*, 1981, 8, 500–502.

RADIOIMMUNOASSAY. In plasma: detection limit 100 pg/ml—D. Arndts *et al.*, *Arzneimittel-Forsch.*, 1979, 29, 532–538.

Disposition in the Body. Well absorbed after oral administration; bioavailability almost 100%. About 30 to 50% of a single dose is excreted in the urine as unchanged drug in 24 hours, and about 20% of a dose is eliminated in the faeces in 4 days. Several inactive metabolites have been detected in urine in small quantities.

THERAPEUTIC CONCENTRATION.

Peak plasma concentrations of 0.001 to 0.0018 $\mu\text{g/ml}$ (mean 0.0014) were attained 90 minutes after administration of a single dose of 0.3 mg to 5 subjects (D. S. Davies *et al.*, *Br. J. clin. Pharmac.*, 1976, 3, 348P).

Following oral administration of 0.075 mg three times a day to 8 subjects, steady-state serum concentrations of 0.0003 to 0.00035 $\mu\text{g/ml}$ were reported (A. Keränen *et al.*, *Eur. J. clin. Pharmac.*, 1978, 13, 97–101).

TOXICITY. Serious toxic effects have been reported after ingestion of doses of 0.4 to 4 mg by children and 4 to 11 mg by adults. However, recovery is usually rapid.

Two women were accidentally given doses of 25 mg instead of 0.025 mg; plasma concentrations of 0.025 and 0.027 $\mu\text{g/ml}$ were reported on admission and at 24 hours, respectively, and decreased with a half-life of 22 hours; the subjects recovered with treatment (J. A. Rotellar *et al.*, *Lancet*, 1981, *i*, 1312).

In a fatality due to clonidine overdose, the following postmortem concentrations were reported: blood 0.023 $\mu\text{g/ml}$, brain 0.024 $\mu\text{g/g}$, kidney 0.086 $\mu\text{g/g}$ (I. Lukkari *et al.*, *Bull. int. Ass. forens. Toxicol.*, 1983, 17(2), 13–14).

HALF-LIFE. Plasma half-life, 10 to 25 hours.

VOLUME OF DISTRIBUTION. 2 to 4 litres/kg.

PROTEIN BINDING. In plasma, about 20 to 40%.

Dose. Usually 0.1 to 1.2 mg of clonidine hydrochloride daily; doses of 1.8 mg or more daily may be given.

Clonixin

Analgesic

2-(3-Chloro-*o*-toluidino)nicotinic acid

$\text{C}_{13}\text{H}_{11}\text{ClN}_2\text{O}_2 = 262.7$

CAS—17737-65-4

A colourless or cream-coloured solid. M.p. about 234°.

Thin-layer Chromatography. System TG—Rf 30. (*Ludy Tenger reagent*, orange.)

Gas Chromatography. System GD—retention time of methyl derivative 1.61 relative to $n\text{-C}_{16}\text{H}_{34}$.

High Pressure Liquid Chromatography. System HV—retention time 0.87 relative to meclofenamic acid.

Ultraviolet Spectrum. Methanol—289 nm ($A_1^1 = 950$ b), 335 nm.

Disposition in the Body. Rapidly absorbed after oral administration. Metabolised by hydroxylation to 4'-hydroxy-, 5'-hydroxy-, and 2'-hydroxymethyl derivatives. About 60% of a dose is excreted in the urine in 24 hours.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 750 mg to 12 subjects, peak serum concentrations of 29 to 66 $\mu\text{g/ml}$ (mean 46) were attained in about 1.7

hours (D. E. Furst and H. E. Paulus, *Clin. Pharmac. Ther.*, 1975, 17, 622–626).

HALF-LIFE. Plasma half-life, about 1.5 hours.

Dose. Clonixin has been given in doses of 600 mg.

Clopamide

Diuretic

Synonym. Chlosudimeprimyl

Proprietary Names. Brinaldix. It is an ingredient of Viskaldix.

4-Chloro-*N*-(2,6-dimethylpiperidino)-3-sulphamoylbenzamide

$C_{14}H_{20}ClN_3O_3S = 345.8$

CAS—636-54-4

A white crystalline powder. M.p. about 246°.

Soluble 1 in about 250 of water, 1 in about 100 of dehydrated alcohol, 1 in about 250 of chloroform, and 1 in 35 of methanol.

Colour Tests. Koppanyi–Zwikker Test—violet; Mercurous Nitrate—black.

Thin-layer Chromatography. *System TA*—Rf 79; *system TD*—Rf 19; *system TE*—Rf 52; *system TF*—Rf 38. (Acidified iodoplatinate solution, strong reaction.)

High Pressure Liquid Chromatography. *System HN*—k' 4.01.

Ultraviolet Spectrum. Aqueous acid—242 nm ($A_1^1 = 346$ b); methanol—232 nm, 277 nm ($A_1^1 = 48$ b), 286 nm ($A_1^1 = 36$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1663, 1172, 1038, 1532, 1285, 928.

Mass Spectrum. Principal peaks at m/z 111, 127, 55, 83, 59, 41, 112, 42.

Dose. 20 to 60 mg daily.

Clopenthixol

Tranquilliser

Synonym. Cloperphenthixan

2-[4-[3-(2-Chlorothioxanthen-9-ylidene)propyl]piperazin-1-yl]-ethanol

$C_{22}H_{25}ClN_2OS = 401.0$

CAS—982-24-1

Cloventhixol Decanoate*Proprietary Name.* Clopixol (injection) $C_{32}H_{43}ClN_2O_2S = 555.2$

A yellowish oily liquid.

Practically **insoluble** in water; soluble in ethanol, chloroform, and ether.**Cloventhixol Hydrochloride***Proprietary Names.* Ciatyl; Clopixol (tablets); Sordinol. $C_{22}H_{25}ClN_2OS \cdot 2HCl = 473.9$

CAS—633-59-0

Crystals. M.p. about 257°, with decomposition.

Freely **soluble** in water; sparingly soluble in ethanol.**Partition Coefficient.** Log *P* (octanol/pH 7.0), 2.3.**Colour Tests.** Formaldehyde-Sulphuric Acid—red (orange fluorescence under ultraviolet light); Liebermann's Test—red; Sulphuric Acid—orange (fluoresces under ultraviolet light).**Thin-layer Chromatography.** System *TA*—Rf 56; system *TB*—Rf 07; system *TC*—Rf 32. (Acidified iodoplatinate solution, positive.)**Gas Chromatography.** System *GA*—RI 2274.**Ultraviolet Spectrum.** Aqueous acid—231 nm ($A_1^1 = 891$ a), 269 nm, 325 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1150, 1090, 757, 740, 1052, 1123 (KBr disk).**Mass Spectrum.** Principal peaks at *m/z* 143, 70, 100, 144, 42, 56, 98, 221.**Quantification.** SPECTROFLUORIMETRY. In serum: cloventhixol decanoate, cloventhixol and des-(2-hydroxyethyl)cloventhixol, limit of detection about 3 ng/ml for cloventhixol decanoate and about 2 ng/ml for cloventhixol and the metabolite—K. Overø, *Acta psychiat. scand.*, 1980, 61, Suppl. 279, 92–103.**HIGH PRESSURE LIQUID CHROMATOGRAPHY.** In serum: *cis*- and *trans*-cloventhixol and des-(2-hydroxyethyl)cloventhixol, sensitivity 500 pg/ml for cloventhixol and 2.5 ng/ml for the metabolite, UV detection—T. Aaes-Jørgensen, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 239–245.

Wavelength

**Disposition in the Body.** Cloventhixol decanoate is slowly absorbed after injection to give peak serum concentrations of cloventhixol and the des-(2-hydroxyethyl) metabolite after about 3 to 7 days. Cloventhixol, the des-(2-hydroxyethyl) metabolite, and their sulphoxide metabolites have been detected in urine together with small amounts of cloventhixol glucuronide.**THERAPEUTIC CONCENTRATION.**A mean minimum steady-state serum concentration of 0.004 µg/ml of cloventhixol was reported in 24 subjects, who had been receiving average doses of 200 mg intramuscularly every 4 weeks, for 5 to 6 months (S. J. Dencker *et al.*, *Acta psychiat. scand.*, 1980, 61, Suppl. 279, 55–63).Following an oral dose of 30 mg of cloventhixol to 1 subject, a peak serum concentration of about 0.005 µg/ml of *cis*-cloventhixol was attained in about 3 hours; the peak concentration of the inactive *trans*-isomer was slightly higher and was attained after 4 hours; the serum concentrations declined slowly and were still measureable after 48 hours; only traces of the des-(2-hydroxyethyl) metabolite were detected (T. Aaes-Jørgensen, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 239–245).**Dose.** The equivalent of 20 to 150 mg of cloventhixol daily; up to 250 mg daily has been given.**Clopidol***Coccidiostat (Veterinary)**Synonyms.* Clopindol; Meticlorpindol.

3,5-Dichloro-2,6-dimethylpyridin-4-ol

 $C_7H_7Cl_2NO = 192.0$

CAS—2971-90-6

A white crystalline powder. M.p. greater than 320°.

Practically **insoluble** in water; slightly soluble in ethanol; soluble in methanol.**Ultraviolet Spectrum.** Ethanol—269 nm ($A_1^1 = 460$ b).**Infra-red Spectrum.** Principal peaks at wavenumbers 1538, 1504, 753, 1618, 762, 1095 (KBr disk).

Ultraviolet Spectrum. Clorazepate dipotassium: aqueous acid—237 nm ($A_1^1 = 747$ b), 287 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1597, 1548, 1300, 702, 1230, 830 (clorazepate dipotassium, KBr disk).

Mass Spectrum. Principal peaks at m/z 242, 43, 270, 269, 241, 103, 243, 76.

Quantification. GAS CHROMATOGRAPHY. In blood or urine: clorazepic acid and desmethyldiazepam, sensitivity 4 ng/ml in blood and 5 ng/ml in urine, ECD; also oxazepam in urine, sensitivity 25 ng/ml, ECD—M. A. Brooks *et al.*, *J. Chromat.*, 1977, 135, 123–131.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: clorazepate dipotassium and desmethyldiazepam, UV detection—P. Colin *et al.*, *J. Chromat.*, 1983, 273; *Biomed. Appl.*, 24, 367–377.

Disposition in the Body. Rapidly decarboxylated below pH 4 to the active metabolite desmethyldiazepam (nordazepam), and thus is absorbed mainly as desmethyldiazepam after oral administration; this is then hydroxylated to form oxazepam which is conjugated with glucuronic acid. Up to about 10% of a dose is excreted in urine in 24 hours, mainly as oxazepam glucuronide, together with small amounts of unchanged clorazepate and conjugated desmethyldiazepam. Oxazepam glucuronide is still detectable in urine 12 days after a single dose.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 15 mg to 4 subjects, peak blood concentrations of desmethyldiazepam of 0.14 to 0.18 $\mu\text{g/ml}$ (mean 0.16) were attained in 0.5 to 1 hour; peak blood-clorazepate concentrations of 0.03 to 0.11 $\mu\text{g/ml}$ (mean 0.06) were reported at about 1 hour (C. W. Abruzzo *et al.*, *J. Pharmacokinet. Biopharm.*, 1977, 5, 377–390). Average steady-state serum concentrations of 0.40 to 0.61 $\mu\text{g/ml}$ (mean 0.48) of desmethyldiazepam were reported in 7 patients receiving daily oral doses of 0.6 mg/kg (A. J. Wilensky *et al.*, *Clin. Pharmac. Ther.*, 1978, 24, 22–30).

TOXICITY. Fatalities from overdosage are rare and recovery from an overdose of 600 mg has been reported.

HALF-LIFE. Plasma half-life, clorazepate about 2 hours, desmethyldiazepam about 40 to 100 hours but there is considerable intersubject variation—see under Nordazepam.

VOLUME OF DISTRIBUTION. Desmethyldiazepam 0.5 to 2.5 litres/kg, increased in elderly subjects.

CLEARANCE. Plasma clearance, desmethyldiazepam about 0.1 to 0.3 ml/min/kg.

Clorazepic Acid

Tranquilliser

7-Chloro-2,3-dihydro-2-oxo-5-phenyl-1H-1,4-benzodiazepine-3-carboxylic acid

$\text{C}_{16}\text{H}_{11}\text{ClN}_2\text{O}_3 = 314.7$

CAS—23887-31-2

Clorazepate Dipotassium

Proprietary Names. Tranxen(e); Tranxilen; Tranxilium.

$\text{C}_{16}\text{H}_{11}\text{ClK}_2\text{N}_2\text{O}_4 = 408.9$

CAS—57109-90-7

A fine, light yellow powder.

Very soluble in water; practically insoluble in organic solvents. In aqueous solution, it converts to the monopotassium salt.

Clorazepate Monopotassium

Proprietary Name. Azene

$\text{C}_{16}\text{H}_{10}\text{ClKN}_2\text{O}_3 = 352.8$

CAS—5991-71-9

A fine, off-white powder.

Very soluble in water; practically insoluble in organic solvents.

Dissociation Constant. pK_a 3.5, 12.5.

Colour Test. Formaldehyde-Sulphuric Acid—orange.

Thin-layer Chromatography. System TA—Rf 84; system TB—Rf 03; system TC—Rf 56; system TD—Rf 34; system TE—Rf 63; system TF—Rf 45.

Gas Chromatography. System GA—clorazepic acid RI 2457, desmethyldiazepam RI 2496, oxazepam RI 2336; system GG—clorazepic acid RI 3125, desmethyldiazepam RI 3041, oxazepam RI 2803.

High Pressure Liquid Chromatography. System HI— k' 1.17; system HK— k' 2.00.

DISTRIBUTION IN BLOOD. Plasma: whole blood ratio, desmethyldiazepam 1.7.

PROTEIN BINDING. In plasma, desmethyldiazepam about 97%.

Dose. 7.5 to 22.5 mg of clorazepate dipotassium daily; up to 60 mg daily has been given.

Clorazepate

Diuretic

Proprietary Name. Nefrolan

6-Chloro-2-cyclohexyl-3-oxoisindoline-5-sulphonamide

$C_{14}H_{17}ClN_2O_3S = 328.8$

CAS—2127-01-7

A white crystalline powder. M.p. about 266°.

Very slightly **soluble** in water; soluble in dimethylformamide, methanol, and solutions of alkali hydroxides.

Colour Test. Koppanyi-Zwicker Test—violet.

Thin-layer Chromatography. System TA—Rf 76; system TD—Rf 31; system TE—Rf 58; system TF—Rf 51. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. System HN—k' 7.26.

Ultraviolet Spectrum. Ethanol—252 nm ($A_1^1 = 246$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1661, 1172, 1234, 1149, 978, 1613 (KBr disk).

Mass Spectrum. Principal peaks at m/z 247, 285, 328, 249, 41, 287, 330, 55.

Disposition in the Body. Absorbed after oral administration. It is almost completely excreted in the urine in 48 hours as three cyclohexane ring-hydroxylated metabolites.

Dose. 10 to 100 mg daily.

Clorgyline *Antidepressant (Monoamine Oxidase Inhibitor)*

Synonym. Clorgiline

N-[3-(2,4-Dichlorophenoxy)propyl]-*N*-methylprop-2-ynylamine

$C_{13}H_{15}Cl_2NO = 272.2$

CAS—17780-72-2

Clorgyline Hydrochloride

$C_{13}H_{15}Cl_2NO \cdot HCl = 308.6$

CAS—17780-75-5

A white crystalline powder. M.p. 102° to 103°.

Very **soluble** in water; soluble in chloroform.

Colour Test. Liebermann's Test—black.

Thin-layer Chromatography. System TA—Rf 67; system TB—Rf 42; system TC—Rf 70. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 1883.

Ultraviolet Spectrum. Aqueous acid—228 nm ($A_1^1 = 310$ b), 282 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1280, 1250, 1055, 1099, 801, 1124.

Dose. Clorgyline hydrochloride has been tried in doses of 10 to 30 mg daily.

Clorprenaline

Sympathomimetic

Synonyms. Chlorprenaline; Isoprophenamine.

1-(2-Chlorophenyl)-2-isopropylaminoethanol

$C_{11}H_{16}ClNO = 213.7$

CAS—3811-25-4

Soluble in chloroform.

Clorprenaline Hydrochloride

$C_{11}H_{16}ClNO \cdot HCl \cdot H_2O = 268.2$

CAS—6933-90-0 (anhydrous); 5588-22-7 (monohydrate)

White crystals. M.p. 161° to 162°.

Soluble in water.

Thin-layer Chromatography. System *TA*—Rf 57; system *TB*—Rf 18; system *TC*—Rf 15. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System *GA*—RI 1604; system *GB*—RI 1614; system *GC*—RI 1880.

High Pressure Liquid Chromatography. System *HA*—k' 1.1.

Ultraviolet Spectrum. Aqueous acid—262 nm, 266 nm ($A_1^1 = 10.1$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1075, 775, 1587, 1041, 1030, 1123.

Mass Spectrum. Principal peaks at m/z 72, 30, 43, 77, 73, 51, 41, 27.

Dose. Clorprenaline hydrochloride has been given in doses of 30 to 80 mg daily.

Clothiapine

Tranquilliser

Synonym. Clotiapipe

Proprietary Name. Entumin(e)

2 - Chloro - 11 - (4 - methylpiperazin - 1 - yl)dibenzo[*b,f*]-[1,4]thiazepine

$C_{18}H_{18}ClN_3S = 343.9$

CAS—2058-52-8

Crystals. M.p. 116° to 122°.

Soluble 1 in 10 of hydrochloric acid.

Thin-layer Chromatography. System *TA*—Rf 59; system *TB*—Rf 41; system *TC*—Rf 59. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1596, 1570, 1548, 1295, 757, 1234 (KBr disk).

Mass Spectrum. Principal peaks at m/z 83, 70, 273, 244, 209, 42, 71, 43.

Dose. Clothiapine has been given in doses of 40 to 120 mg daily.

Clotrimazole

Antifungal

Synonym. Chlortritylimidazol

Proprietary Names. Canesten; Eparol; Gyne-Lotrimin; Lotrimin; Mycelex; Trimysten.

1 - (α - 2 - Chlorotrityl)imidazole

$C_{22}H_{17}ClN_2 = 344.8$

CAS—23593-75-1

A white to pale yellow crystalline powder. M.p. about 142°, with decomposition.

Practically **insoluble** in water; freely soluble in ethanol and chloroform; slightly soluble in ether.

Gas Chromatography. System *GA*—RI 2100.

Ultraviolet Spectrum. Methanol—254 nm, 260 nm ($A_1^1 = 20$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 765, 752, 708, 1075, 741, 1205 (KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 277, 279, 165, 278, 241, 239, 242, 240.

Uses. Topically in a concentration of 1 or 2% or as vaginal tablets.

**Cloxacillin**

Antibiotic

(6*R*)-6-[3-(2-Chlorophenyl)-5-methylisoxazole-4-carboxamido]penicillanic acid

$C_{19}H_{18}ClN_3O_5S = 435.9$

CAS—61-72-3

**Cloxacillin Sodium**

Proprietary Names. Austrastaph; Bactopen; Cloxapen; Cloxilean; Cloxyphen; Ekvacillin; Novocloxin; Orbenin(e); Staphybiotic; Tegopen. It is an ingredient of Ampiclox.

$C_{19}H_{17}ClN_3NaO_5S \cdot H_2O = 475.9$

CAS—642-78-4 (anhydrous); 7081-44-9 (monohydrate)

A white, hygroscopic, crystalline powder.

Soluble 1 in 2.5 of water, 1 in 30 of ethanol, and 1 in 500 of chloroform.

Dissociation Constant. pK_a 2.7 (25°).

Ultraviolet Spectrum. Cloxacillin sodium: aqueous acid—352 nm ($A_1^1 = 67$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1598, 1620, 1765, 1495, 1659, 771 (cloxacillin sodium, KBr disk).

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In serum or urine: sensitivity 50 ng/ml, UV detection—F. W. Teare *et al.*, *J. pharm. Sci.*, 1982, 71, 938-941. In serum: sensitivity 500 ng/ml, UV detection—S. J. Soldin *et al.*, *Ther. Drug Monit.*, 1980, 2, 417-422.

Disposition in the Body. Incompletely absorbed after oral administration. About 35% of an oral dose is excreted in the urine unchanged in 12 hours, together with about 11% as penicilloic acid; about 10% of a dose is excreted in the bile.

HALF-LIFE. Plasma half-life, about 0.5 to 1.5 hours.

VOLUME OF DISTRIBUTION. About 0.1 litre/kg.

PROTEIN BINDING. In plasma, about 94%.

Dose. Usually the equivalent of 2 g of cloxacillin daily.

Clozapine

Tranquilliser

Proprietary Name. Leponex

8 - Chloro - 11 - (4 - methylpiperazin - 1 - yl) - 5*H* - dibenzo-*[b,e]*[1,4]diazepine

$C_{18}H_{19}ClN_4 = 326.8$

CAS—5786-21-0

Yellow crystals. M.p. about 183°.

Colour Tests. Formaldehyde-Sulphuric Acid—yellow.

Cold nitric acid gives a red colour.

Thin-layer Chromatography. System TA—Rf 57; system TB—Rf 04; system TC—Rf 38; system TD—Rf 04; system TE—Rf 63; system TF—Rf 05.

Gas Chromatography. System GA—RI 2967; system GG—RI 3455.

Ultraviolet Spectrum. Aqueous acid—245 nm, 297 nm; aqueous alkali—238 nm, 261 nm, 297 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1600, 1560, 758, 1136, 1101, 1117.

Mass Spectrum. Principal peaks at m/z 243, 256, 70, 245, 192, 227, 258, 326.

Dose. Clozapine has been given in doses of 150 to 600 mg daily.

Cocaine

Local Anaesthetic

Synonyms. Methyl Benzoylecgonine; Neurocaine.

(1*R*,2*R*,3*S*,5*S*)-2-Methoxycarbonyltropan-3-yl benzoate

$C_{17}H_{21}NO_4 = 303.4$

CAS—50-36-2

An alkaloid obtained from coca, the dried leaves of *Erythroxylum coca* and other species of *Erythroxylum* (Erythroxylaceae), or by synthesis from ecgonine.

A white crystalline, slightly volatile, powder. M.p. 96° to 98°.

Soluble 1 in 600 of water, 1 in 7 of ethanol, 1 in about 0.5 of chloroform, and 1 in 4 of ether.

Cocaine Hydrochloride

Synonym. Cocainium Chloride

Proprietary Name. It is an ingredient of Mydracaine (injection).

$C_{17}H_{21}NO_4 \cdot HCl = 339.8$

CAS—53-21-4

Hygroscopic colourless crystals or white crystalline powder. M.p. about 197°, with decomposition.

Soluble 1 in 0.5 of water, 1 in 3.5 to 1 in 4.5 of ethanol, and 1 in 15 to 1 in 18 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 8.6 (20°).

Colour Test. *p*-Dimethylaminobenzaldehyde (100° for 3 min)—red.

Thin-layer Chromatography. *System TA*—Rf 65; *system TB*—Rf 47; *system TC*—Rf 47; *system TL*—Rf 54. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—cocaine RI 2187, benzoylecgonine RI 2570, ecgonine not eluted; *system GF*—RI 2550.

High Pressure Liquid Chromatography. *System HA*—cocaine k' 2.8, benzoylecgonine k' 0.9 (tailing peak), ecgonine k' 1.1; *system HQ*—cocaine k' 2.68, benzoylecgonine k' 5.68.

Ultraviolet Spectrum. Aqueous acid—233 nm ($A_1^1 = 430$ a), 275 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1710, 1738, 1275, 1110, 712, 1037 (KBr disk).

Mass Spectrum. Principal peaks at m/z 82, 182, 83, 105, 303, 77, 94, 96; benzoylecgonine 124, 82, 168, 77, 105, 42, 94, 83.

Quantification. GAS CHROMATOGRAPHY. In plasma, urine or erythrocytes: ECD—J. I. Javaid *et al.*, *J. Chromat.*, 1978, 152, 105–113. In whole blood or plasma: sensitivity 20 ng/ml, AFID—B. H. Dvorchik *et al.*, *J. Chromat.*, 1977, 135, 141–148.

GAS CHROMATOGRAPHY—MASS SPECTROMETRY. In biological samples: cocaine, benzoylecgonine and norcocaine, sensitivity 5 ng/ml—D. M. Chinn *et al.*, *J. analyt. Toxicol.*, 1980, 4, 37–42.

In urine: ecgonine methyl ester, sensitivity 100 ng/ml—J. J. Ambre *et al.*, *J. analyt. Toxicol.*, 1982, 6, 26–29.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or tissues: cocaine and metabolites, limit of detection <1 µg/ml, UV detection—M. A. Evans and T. Morarity, *J. analyt. Toxicol.*, 1980, 4, 19–22.

RADIOIMMUNOASSAY. In urine: benzoylecgonine (comparison with TLC, GLC and enzyme immunoassay), sensitivity 2 ng/ml—S. J. Mulé *et al.*, *Clin. Chem.*, 1977, 23, 796–801. In blood or urine: benzoylecgonine (comparison with HPLC), limit of detection 20 ng/ml—K. Robinson and R. N. Smith, *J. Pharm. Pharmacol.*, 1984, 36, 157–162.

REVIEWS. J. E. Wallace *et al.*, *J. analyt. Toxicol.*, 1977, 1, 20–26 and J. E. Lindgren, *J. Ethnopharmacol.*, 1981, 3, 337–351.

Disposition in the Body. Cocaine is normally only used as a surface anaesthetic in the eye, ear, nose, and throat because of the possibility of systemic toxic effects when given by other routes. Addicts may inject it or use it as a snuff; it is less toxic when taken orally due to hydrolysis in the gastro-intestinal tract.

The main metabolites are benzoylecgonine, ecgonine, and ecgonine methylester, all of which are inactive; some norcocaine, an active metabolite, may also be produced; other metabolites which have been reported are ethylecgonine, hydroxycocaine, and methylecgonidine. About 1 to 9% of a daily intravenous dose of 120 mg of cocaine is excreted unchanged in the urine, together with 35 to 55% as benzoylecgonine; the excretion of unchanged drug is increased when the urine is acid; some ecgonine may also be present. After an intranasal dose of 1.5 mg/kg, up to 4% of the dose is excreted in the urine unchanged in 24 hours, and 16 to 36% of the dose is excreted as benzoylecgonine. About 30 to 60% of an oral, intranasal, or intravenous dose is excreted in the urine as ecgonine methyl ester. No unchanged drug is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.

After a dose of 1.5 mg/kg, administered intranasally to 9 subjects, peak plasma concentrations of 0.12 to 0.47 µg/ml were attained in 1 hour (C. Van Dyke *et al.*, *Science*, 1976, 191, 859–861).

Following a dose of 16 mg, administered intravenously to 10 subjects, peak plasma concentrations of 0.09 to 0.31 µg/ml were reported after 5 minutes (J. I. Javard *et al.*, *Science*, 1978, 202, 227–228).

After a dose of 2 mg/kg, administered orally to 3 subjects, peak plasma concentrations of 0.10 to 0.42 µg/ml were attained in 50 to 90 minutes (C. Van Dyke *et al.*, *Science*, 1978, 200, 211–213).

TOXICITY. The estimated minimum lethal dose is 1.2 g but susceptible persons have died from doses as small as 30 mg when applied to mucous membranes; addicts may be able to tolerate up to 5 g a day. Toxic effects have been noted with blood concentrations in the range 0.25 to 5 µg/ml and fatalities have occurred with concentrations of 1 µg/ml or more.

In 5 fatalities attributed to intravenous overdoses of cocaine, the following postmortem tissue concentrations, µg/ml or µg/g (mean), were reported:

	Cocaine	Benzoylecgonine
Blood	0–7.6 (2.7)	1.0–7.4 (4.4)
Liver	0.04–3.2 (1.2)	1.4–7.1 (4.2)
Urine	38.4–118.6 (76)	15–185 (110)

In one case, brain concentrations of 10.4 and 1.0 µg/g and kidney concentrations of 0.1 and 2.9 µg/g were reported for cocaine and benzoylecgonine, respectively. Norcocaine was detected in low concentrations in some samples (D. M. Chinn *et al.*, *J. analyt. Toxicol.*, 1980, 4, 37–42).

In 4 fatalities due to the ingestion of large amounts of cocaine (more than 1 g), postmortem blood concentrations ranged from 7 to 12.8 µg/ml (mean 8.9), compared with blood concentrations of 0.1 to 11 µg/ml (mean 3) in 6 fatalities due to intravenous cocaine, and 0.3 to 11 µg/ml (mean 4.4) in 4 fatalities due to intranasal overdose (C. V. Wetli and R. K. Wright, *J. Am. med. Ass.*, 1979, 241, 2519–2522).

A known addict was thought to have ingested 2 to 3 g of stolen cocaine whilst being taken into custody; he died about 5 hours later. Postmortem concentrations were: blood 8 µg/ml, kidney 12 µg/g, liver 8 µg/g, urine 50 µg/ml (K. R. Price, *J. forens. Sci. Soc.*, 1974, 14, 329–333).

HALF-LIFE. Plasma half-life, 0.7 to 1.5 hours (dose-dependent).

VOLUME OF DISTRIBUTION. About 1 to 3 litres/kg.

CLEARANCE. Plasma clearance, 10 to 30 ml/min/kg (dose-dependent).

Use. Cocaine hydrochloride is used in concentrations of 1 to 20%, for local anaesthesia.

An alkaloid obtained from opium or prepared by methylation of morphine.

Colourless crystals or white crystalline powder which effloresces slowly in dry air and is affected by light. M.p. 154° to 158°.

Soluble 1 in 120 of water, 1 in 15 of boiling water, 1 in 2 of ethanol, 1 in 0.5 of chloroform, and 1 in 50 of ether.

Codeine Hydrochloride

$C_{18}H_{21}NO_3 \cdot HCl \cdot 2H_2O = 371.9$

CAS—1422-07-7 (anhydrous)

A white crystalline powder. M.p. about 280°, with some decomposition.

Soluble 1 in 30 of water, 1 in 100 of ethanol (90%), and 1 in 800 of chloroform.

Codeine Phosphate

Synonym. Methylmorphine Phosphate

Proprietary Names. Codlin; Paveral; Tricodine.

Codeine phosphate is an ingredient of many proprietary preparations—see *Martindale, The Extra Pharmacopoeia*, 28th Edn.

$C_{18}H_{21}NO_3 \cdot H_3PO_4 \cdot \frac{1}{2}H_2O = 406.4$

CAS—52-28-8 (anhydrous); 41444-62-6 (hemihydrate); 5913-76-8 (sesquihydrate)

Small colourless crystals or white crystalline powder.

Soluble 1 in 4 of water, 1 in 450 of ethanol, and 1 in 125 of boiling ethanol; practically insoluble in chloroform and ether.

Codeine Sulphate

Synonym. Codeine Sulfate

Proprietary Name. It is an ingredient of Bepro.

$(C_{18}H_{21}NO_3)_2 \cdot H_2SO_4 \cdot 3H_2O = 750.9$

CAS—1420-53-7 (anhydrous); 6854-40-6 (trihydrate)

White crystals or crystalline powder.

Soluble 1 in 30 of water and 1 in 1300 of ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 8.2 (20°).

Partition Coefficient. Log *P* (octanol/pH 7.4), 0.6.

Colour Tests. Liebermann's Test—black; Mandelin's Test—green; Marquis Test—violet.

Thin-layer Chromatography. *System TA*—Rf 33; *system TB*—Rf 06; *system TC*—Rf 18. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, violet.)

Gas Chromatography. *System GA*—codeine RI 2376, morphine RI 2454, norcodeine RI 2388; *system GB*—RI 1600; *system GC*—codeine RI 2681, morphine RI 2542; *system GF*—RI 2860.

High Pressure Liquid Chromatography. *System HA*—codeine *k'* 4.8 (tailing peak), morphine *k'* 3.8 (tailing peak), norcodeine *k'* 3.1 (tailing peak); *system HC*—codeine *k'* 1.21, morphine *k'* 1.30, norcodeine *k'* 3.51; *system HS*—codeine *k'* 1.90, morphine *k'* 5.16.

Ultraviolet Spectrum. Aqueous acid—285 nm ($A_1^{1\%} = 55$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1052, 1268, 1500, 1111, 793, 934, (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 299, 42, 162, 124, 229, 59, 300, 69; morphine 285, 162, 42, 215, 286, 124, 44, 284; norcodeine 285, 81, 215, 148, 286, 164, 110, 115.

Codeine

Narcotic Analgesic

Synonym. Morphine Methyl Ether

Proprietary Name. Codiccept

3 - O - Methylmorphine monohydrate

$C_{18}H_{21}NO_3 \cdot H_2O = 317.4$

CAS—76-57-3 (anhydrous); 6059-47-8 (monohydrate)

Quantification. GAS CHROMATOGRAPHY. In blood, urine or tissues: codeine and morphine, sensitivity 20 ng in blood, 500 ng in urine and tissues, FID—G. R. Nakamura and E. L. Way, *Analyt. Chem.*, 1975, 47, 775–778.

GAS CHROMATOGRAPHY (CAPILLARY COLUMN). In biological fluids: detection limit 5 ng/ml for codeine and 1 ng/ml for morphine, ECD—P. O. Edlund, *J. Chromat.*, 1981, 206, 109–116.

- GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In blood, urine or tissues: sensitivity 13 ng/ml for codeine and morphine—N. B. Wu Chen *et al.*, *J. analyt. Toxicol.*, 1982, 6, 231–234.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, UV detection—V. Nitsche and H. Mascher, *J. pharm. Sci.*, 1984, 73, 1556–1558. In urine: codeine, norcodeine and morphine, sensitivity 25 ng/ml, UV detection—B. L. Posey and S. N. Kimble, *J. analyt. Toxicol.*, 1984, 8, 68–74.

- RADIOIMMUNOASSAY. In plasma: sensitivity <1 ng/ml—J. W. A. Findlay *et al.*, *Life Sci.*, 1976, 19, 389–394.

Disposition in the Body. Well absorbed after oral administration; bioavailability about 50%. Metabolised in the liver by *O*-demethylation to form morphine, *N*-demethylation to form norcodeine, and conjugation to form glucuronides and sulphates of both unchanged drug and its metabolites. After an oral dose, about 86% is excreted in the urine in 24 hours; of the excreted material, 40 to 70% is free or conjugated codeine, 5 to 15% is free or conjugated morphine, 10 to 20% is free or conjugated norcodeine, and trace amounts may be free or conjugated normorphine; some of the dose is excreted in the bile and trace amounts are found in the faeces; unchanged drug accounts for 6 to 8% of the dose in urine in 24 hours but this may increase to about 10% when the urinary pH is decreased. After an intramuscular dose, 15 to 20% is excreted unchanged in acid urine in 24 hours. Small amounts of hydrocodone, norhydrocodone, 6 α -hydrocodol, and 6 β -hydrocodol have also been detected in urine.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 60 mg of codeine phosphate in combination with 650 mg of aspirin, administered to 12 subjects, peak plasma concentrations of 0.11 to 0.23 μ g/ml (mean 0.16) of codeine were attained in 0.5 to 1.5 hours, and peak plasma concentrations of morphine of 0.0003 to 0.014 μ g/ml (mean 0.007) were reported at 1.5 hours (J. W. A. Findlay *et al.*, *Clin. Pharmac. Ther.*, 1978, 24, 60–68).

TOXICITY. The estimated minimum lethal dose is 800 mg, but codeine is much less toxic than morphine and death directly attributable to codeine is rare; in most fatalities involving codeine, other drugs and/or alcohol are also present. Drug addicts may use doses up to 10 times normal before showing toxic effects, whilst children may show toxicity with only 1/20th of the dose.

Concentrations of codeine in the blood of 1.4 to 5.6 μ g/ml (mean 3.6) were found in 8 fatal cases of codeine overdose (J. A. Wright *et al.*, *Clin. Toxicol.*, 1975, 8, 457–463).

In 39 fatal cases in which codeine was implicated, the postmortem blood concentrations for codeine ranged from <0.1 μ g/ml to 8.8 μ g/ml (mean 1.2), and for morphine from <0.1 μ g/ml to 0.7 μ g/ml (mean 0.16); in 22 of these cases, the following concentrations, μ g/ml or μ g/g (mean), in other tissues and fluids were reported:

	Codeine	Morphine
Bile	0.5–43 (11)	<0.1–119 (33)
Kidney	<0.1–36.3 (7)	<0.1–12.4 (2)
Liver	<0.1–45 (5)	<0.1–6.4 (2)
Urine	3.2–229 (60)	<0.1–69.8 (20)

In all cases, other drugs were also present (G. R. Nakamura *et al.*, *J. forens. Sci.*, 1976, 21, 518–524).

In 2 fatalities involving the ingestion of large numbers of codeine tablets, postmortem blood concentrations of codeine of 15 and 48 μ g/ml were reported; urine concentrations were 155 and 370 μ g/ml; in both cases alcohol had also been ingested and in one case a low concentration of salicylate was also found in the blood (M. A. Peat and A. Sengupta, *Forens. Sci.*, 1977, 9, 21–32).

HALF-LIFE. Plasma half-life, 2 to 4 hours.

VOLUME OF DISTRIBUTION. About 3.5 litres/kg.

CLEARANCE. Plasma clearance, 10 to 15 ml/min/kg.

PROTEIN BINDING. In plasma, about 7 to 25%.

Dose. 10 to 60 mg up to 6 times a day.

Co-dergocrine Mesylate

Vasodilator

Synonyms. Co-dergocrine Methanesulphonate; DEA; DHAE; Dihydroergotoxine Mesylate; Dihydrogenated Ergot Alkaloids; Hydrogenated Ergot Alkaloids.

Proprietary Names. Circanol; Deapril-ST; Hydergin(e); Progeril.

A mixture in equal proportions of dihydroergocornine mesylate ($C_{31}H_{41}N_5O_5 \cdot CH_3O_3S = 659.8$), dihydroergocristine mesylate ($C_{35}H_{41}N_5O_5 \cdot CH_3O_3S = 707.8$), and α - and β -dihydroergocryptine mesylates ($C_{32}H_{43}N_5O_5 \cdot CH_3O_3S = 673.8$) in the ratio 2:1. CAS—11032-41-0 (co-dergocrine); 8067-24-1 (mesylate)

A white to yellowish-white powder. M.p. 196° to 206° , with decomposition.

Soluble 1 in 50 of water, 1 in 30 of ethanol, 1 in 10 of acetone, and 1 in 100 of chloroform; practically insoluble in ether.

Dissociation Constant. pK_a 6.9 (24°).

Thin-layer Chromatography. Co-dergocrine: system TA—Rf 66; system TB—Rf 01; system TC—Rf 48; system TL—Rf 29; system TM—Rf 64.

High Pressure Liquid Chromatography. System HP—dihydroergocristine k' 18.3, dihydroergocryptine k' 15.9.

Infra-red Spectrum. Principal peaks at the following wavenumbers (all KBr disk):

Dihydroergocornine 1633, 1662, 1720, 1705, 1558, 768

Dihydroergocristine 1635, 1728, 1510, 1215, 760, 1540

Dihydroergocryptine mesylate 1633, 1210, 1172, 1048, 1675, 1732

Mass Spectrum. Principal peaks at the following m/z :

Co-dergocrine 70, 154, 125, 41, 43, 155, 42, 225

Dihydroergocornine 70, 71, 269, 154, 195, 55, 59, 57

Dihydroergocristine 125, 70, 91, 153, 41, 244, 43, 71

Dihydroergocryptine 154, 70, 155, 167, 223, 225, 349, 153

Quantification. HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit 700 pg/ml, fluorescence detection—L. Zecca *et al.*, *J. Chromat.*, 1983, 272; *Biomed. Appl.*, 23, 401–405.

RADIOIMMUNOASSAY. In plasma: detection limit 10 pg/ml—W. Loh and B. G. Woodcock, *Arzneimittel-Forsch.*, 1983, 33, 568–570.

Disposition in the Body. Poorly absorbed after oral administration; bioavailability 5 to 12%.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 4.5 mg to 8 subjects, peak plasma concentrations of 0.0003 to 0.0011 $\mu\text{g/ml}$ (mean 0.0006) were attained in 0.2 to 1.2 hours (B. G. Woodcock *et al.*, *Clin. Pharmac. Ther.*, 1982, 32, 622–627).

HALF-LIFE. Plasma half-life, 8 to 25 hours (mean 13).

VOLUME OF DISTRIBUTION. 10 to 20 litres/kg.

CLEARANCE. Plasma clearance, 20 to 30 ml/min/kg.

REFERENCE. B. G. Woodcock *et al.*, *Clin. Pharmac. Ther.*, 1982, 32, 622–627.

Dose. Up to 4.5 mg daily, by mouth; 0.75 to 3 mg daily, sublingually.

Colchicine

Gout Suppressant

Proprietary Names. Colchineseos; Colcin; Colgout; Coluric.

(S)-N-(5,6,7,9-Tetrahydro-1,2,3,10-tetramethoxy-9-oxobenzo[a]heptalen-7-yl)acetamide

$C_{22}H_{25}NO_6 = 399.4$

CAS—64-86-8

An alkaloid obtained from the corm and seeds of the meadow saffron, *Colchicum autumnale* (Liliaceae) and other *Colchicum* species.

Pale yellow to greenish-yellow crystals, or amorphous scales or powder, darkening on exposure to light. M.p. about 157° .

Soluble 1 in about 20 of water, but moderately concentrated aqueous solutions may deposit crystals of a sesquihydrate, which is less soluble in cold water than the anhydrous alkaloid. Freely soluble in ethanol and chloroform; soluble 1 in 160 of ether.

Dissociation Constant. pK_a 1.7 (20°).

Partition Coefficient. Log P (octanol), 1.0.

Colour Tests. Liebermann's Test—green; Mandelin's Test—green; Marquis Test—yellow.

Thin-layer Chromatography. System TA—Rf 55; system TB—Rf 00; system TC—Rf 37. (Van Urk reagent, yellow.)

High Pressure Liquid Chromatography. System HA—k' 0.2.

Ultraviolet Spectrum. Ethanol—243 nm ($A_1^1 = 730$ a), 350 nm ($A_1^1 = 425$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1250, 1550, 1588, 1610, 1090, 1655 (KBr disk).

Mass Spectrum. Principal peaks at m/z 312, 43, 399, 297, 356, 281, 371, 311.

Quantification. SPECTROFLUORIMETRY. In plasma or urine—R. Bourdon and M. Galliot, *Annls Biol. clin.*, 1976, 34, 393–401.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: sensitivity 5 ng/ml, UV detection—D. Jarvie *et al.*, *Clin. Toxicol.*, 1979, 14, 375–381. In whole blood: sensitivity 10 ng/ml, UV detection—Y. H. Caplan *et al.*, *J. analyt. Toxicol.*, 1980, 4, 153–155.

RADIOIMMUNOASSAY. In serum: sensitivity 350 pg/ml—J. M. Scherrmann *et al.*, *J. Pharm. Pharmac.*, 1980, 32, 800–802.

Disposition in the Body. Readily absorbed after oral administration; metabolised by demethylation to desmethylcolchicine. Up to 50% of a dose is excreted in the urine in 48 hours as unchanged drug and metabolites; colchicine is excreted in the bile and undergoes enterohepatic circulation.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 1 mg to 10 subjects, a mean peak plasma concentration of 0.003 $\mu\text{g/ml}$ was reported at 0.5 to 2 hours (S. L. Wallace and N. H. Ertel, *Metabolism*, 1973, 22, 749–753).

Steady-state serum concentrations of 0.0003 to 0.0024 $\mu\text{g/ml}$ were reported after daily oral doses of 1 mg given to 8 subjects (H. Halkin *et al.*, *Clin. Pharmac. Ther.*, 1980, 28, 82–87).

TOXICITY. The minimum lethal dose in man is about 6 mg although recovery has occurred after much larger doses.

In a reported fatality following the ingestion of 7.5 mg of colchicine together with unknown quantities of phenylbutazone and alcohol, a plasma concentration of 0.02 µg/ml was obtained at 6 hours which decreased to less than 0.005 µg/ml at 24 hours; death occurred 45 hours after ingestion (D. Jarvie *et al.*, *ibid.*).

In a fatality due to the ingestion of colchicine, the following postmortem colchicine concentrations were reported: bile 3.2 µg/ml, liver 1 µg/g. In a second fatality, desmethylcolchicine concentrations were: liver 3.3 µg/g, urine 12.5 µg/ml (W. J. Allender, *J. forens. Sci.*, 1982, 27, 944-947).

A blood concentration of 0.25 µg/ml was reported in 1 subject, 2 hours after the ingestion of 20 mg of colchicine; death occurred after 40 hours and colchicine was not detectable in the postmortem blood (Y. H. Caplan *et al.*, *ibid.*).

HALF-LIFE. Plasma half-life, about 1 hour.

VOLUME OF DISTRIBUTION. About 0.7 to 2 litres/kg.

PROTEIN BINDING. In plasma, about 30 to 50%.

Dose. 1 mg initially, followed by 500 µg every 2 or 3 hours; maximum total dose of 10 mg.

Conessine

Anti-amoebic

3β-Dimethylaminocon-5-enine

C₂₄H₄₀N₂ = 356.6

CAS—546-06-5

An alkaloid obtained from the seeds of *Holarrhena antidysenterica* (Apocynaceae).

A white crystalline powder. M.p. 127° to 129°.

Sparingly soluble in water.

Conessine Hydrobromide

Synonym. Conessine Bromide

C₂₄H₄₀N₂·2HBr = 518.4

CAS—5913-82-6

White acicular crystals or microcrystalline powder. M.p. 340°, with decomposition.

Soluble 1 in 5 of water and 1 in 11 of ethanol (90%); very slightly soluble in ether.

Colour Tests. Mandelin's Test—yellow; Marquis Test—yellow→orange.

Thin-layer Chromatography. *System TA*—Rf 28; *system TB*—Rf 49; *system TC*—Rf 03. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Mass Spectrum. Principal peaks at *m/z* 84, 71, 85, 82, 80, 341, 70, 356.

Dose. Conessine hydrobromide was formerly given in doses of 300 to 500 mg daily.

Coniine

Alkaloid

Synonyms. Cicutine; Conicine; Conine.

(S)-2-Propylpiperidine

C₈H₁₇N = 127.2

CAS—458-88-8

An alkaloid obtained mainly from the fruits and leaves of hemlock, *Conium maculatum* (Umbelliferae).

An almost colourless volatile liquid. F.p. -2°. B.p. 166°.

Soluble 1 in 100 of water; miscible with ethanol and ether; slightly soluble in chloroform.

Coniine Hydrobromide

C₈H₁₇N·HBr = 208.1

CAS—637-49-0

Colourless crystals. M.p. about 211°.

Soluble 1 in 2 of water and 1 in 3 of ethanol; soluble in chloroform and ether.

Dissociation Constant. pK_a 11.0 (25°).

Thin-layer Chromatography. *System TA*—Rf 26. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—not eluted.

Ultraviolet Spectrum. Aqueous acid—266 nm (A₁¹ = 6 b); aqueous alkali—262 nm, 268 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1033, 1007, 1575, 1300, 1078, 1139 (coniine hydrobromide, Nujol mull).

Mass Spectrum. Principal peaks at *m/z* 84, 82, 80, 56, 43, 28, 30, 41.

Disposition in the Body.

TOXICITY. Coniine is well absorbed from the gastro-intestinal tract and is very poisonous; the estimated minimum lethal dose is 150 mg and toxic symptoms may occur after ingestion of 60 mg. Death may occur within 30 minutes or be delayed 3 to 12 hours. Coniine resembles nicotine in its peripheral action but produces more pronounced paralysis of the central nervous system and of the skeletal muscle nerve-endings.

Cortisone*Corticosteroid*

Synonyms. Compound E; 11-Dehydro-17-hydroxycorticosterone.

17 α ,21-Dihydroxypregn-4-ene-3,11,20-trione

$C_{21}H_{28}O_5 = 360.4$

CAS—53-06-5

Crystals. M.p. 217° to 224°, with some decomposition. Very slightly **soluble** in water; soluble in ethanol; sparingly soluble in chloroform and ether.

Cortisone Acetate

Synonym. Cortisone 21-Acetate

Proprietary Names. Adreson; Cortate; Cortelan; Cortisol; Cortison; Cortistab; Cortisyl; Cortone; Cortone Acetate; Sterop.

Note. The name Cortisol is also applied to hydrocortisone.

$C_{23}H_{30}O_6 = 402.5$

CAS—50-04-4

A white crystalline powder. M.p. about 240°, with decomposition.

Soluble 1 in 5000 of water, 1 in 300 to 1 in 350 of ethanol, and 1 in 4 of chloroform; slightly soluble in ether.

Colour Tests. Naphthol-Sulphuric Acid—orange-brown/orange; Sulphuric Acid—yellow (green fluorescence under ultraviolet light).

Thin-layer Chromatography. Cortisone acetate: *system TP*—Rf 72; *system TQ*—Rf 28; *system TR*—Rf 55; *system TS*—Rf 00. (DPST solution).

High Pressure Liquid Chromatography. *System HT*—k' 2.4.

Ultraviolet Spectrum. Cortisone acetate: ethanol—240 nm ($A_1^1 = 390$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1700, 1660, 1235, 1720, 1275, 1750 (cortisone acetate, KBr disk).

Dose. 25 to 50 mg of cortisone acetate daily.

Cotarnine*Haemostatic*

8-Methoxy-2-methyl-6,7-methylenedioxy-1,2,3,4-tetrahydroisoquinolin-1-ol

$C_{12}H_{15}NO_4 = 237.3$

CAS—82-54-2

An alkaloid obtained by oxidising noscapine with nitric acid. Crystals. M.p. 132° to 137°, with decomposition. Slightly **soluble** in water; soluble in ethanol, chloroform, and ether.

Cotarnine Chloride

Synonyms. Cotarnine Hydrochloride; Stypticine.

$C_{12}H_{14}ClNO_3 \cdot 2H_2O = 291.7$

CAS—10018-19-6 (anhydrous); 16210-52-9 (dihydrate)

A pale yellow deliquescent powder. M.p. 197°. When heated to decomposition, highly toxic fumes are evolved.

Soluble in water, ethanol, and chloroform; practically insoluble in ether.

Colour Tests. Liebermann's Test—black; Mandelin's Test—red-orange→brown.

Thin-layer Chromatography. *System TA*—Rf 02. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. *System GA*—RI 1808.

High Pressure Liquid Chromatography. *System HA*—k' 8.2 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—253 nm ($A_1^1 = 582$ b), 332 nm ($A_1^1 = 666$ b); aqueous alkali—286 nm, 330 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1605, 1086, 1490, 1655, 1505, 1300 (cotarnine chloride, KCl disk).

Dose. Cotarnine chloride was formerly given in doses of 20 to 100 mg.

Coumatetralyl*Rodenticide*

Proprietary Name. Racumin

4-Hydroxy-3-(1,2,3,4-tetrahydro-1-naphthyl)coumarin

$C_{19}H_{16}O_3 = 292.3$

CAS—5836-29-3

A yellowish-white crystalline powder. M.p. 172° to 176°.

Practically **insoluble** in water; soluble in ethanol and acetone; slightly soluble in ether.

Thin-layer Chromatography. *System TD*—Rf 73; *system TE*—Rf 13; *system TF*—Rf 74. (Location under ultraviolet light, pink fluorescence; acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—275 nm, 285 nm, 309 nm; aqueous alkali—311 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1615, 762, 740, 1685, 1250, 1570.

Mass Spectrum. Principal peaks at m/z 292, 121, 188, 130, 115, 91, 128, 129.

Cresol

Disinfectant

Synonyms. Cresylic Acid; Tricresol. It is an ingredient of Lysol (Cresol and Soap Solution containing 50% v/v of cresol).

Note. The use of the name Lysol is limited. In some countries it is a trade-mark applied to a product of different composition.

Proprietary Name. It is an ingredient of Lyseptol.

Cresol is a mixture of *o*-, *m*-, and *p*-cresols ($\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{OH} = 108 \cdot 1$), in which the *m*-isomer predominates, and of other phenols obtained from coal tar.

CAS—1319-77-3; 95-48-7 (*o*-cresol); 108-39-4 (*m*-cresol); 106-44-5 (*p*-cresol)

An almost colourless to pale brownish-yellow liquid, becoming darker with age or on exposure to light. Wt per ml 1.029 to 1.044 g. B.p. 195° to 205°.

Almost completely **soluble** 1 in 50' of water; miscible with ethanol, chloroform, and ether.

Dissociation Constant. pK_a *m*-cresol 10.1, *o*-cresol 10.3, *p*-cresol 10.3 (25°).

Colour Tests. Folin-Ciocalteu Reagent—blue; Liebermann's Test—black; Potassium Dichromate—brown (*o*-cresol—30 s, *m*-cresol—2 min).

Heat with about an equal quantity of phthalic anhydride and a few drops of *sulphuric acid* until the mixture is orange-brown; cool the mixture with a few drops of water and make alkaline with *sodium hydroxide solution*—red with *o*-cresol and blue-violet with *m*-cresol.

Ultraviolet Spectrum. Aqueous alkali—239 nm ($A_1^1 = 949$ b), 290 nm ($A_1^1 = 251$ b); ethanol—275 nm ($A_1^1 = 163$ b), 279 nm ($A_1^1 = 145$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1209, 816, 1515, 741, 1176, 1105 (*p*-cresol, Nujol mull).

Mass Spectrum. Principal peaks at m/z 107, 108, 77, 79, 51, 39, 53, 50 (*p*-cresol).

Quantification. GAS CHROMATOGRAPHY. In blood, urine or tissues: sensitivity 20 µg/ml, FID—A. M. Bruce *et al.*, *Medicine, Sci. Law*, 1976, 16, 171–176.

Disposition in the Body. Absorbed after ingestion, and through the skin and mucous membranes. It is metabolised by conjugation and oxidation; *p*-cresol is endogenously produced in normal subjects, and may be present in urine at concentrations of 20 to 200 µg/ml (mainly in conjugated form).

TOXICITY. The estimated minimum lethal dose is 2 g, and the maximum permissible atmospheric concentration is 5 ppm.

In 2 fatalities due to the ingestion of cresol, the following postmortem tissue concentrations were reported: blood 71, 190 µg/ml; brain 2.8, – µg/g; kidney 396, – µg/g; liver 900, 480 µg/g; urine –, 304 µg/ml (A. M. Bruce *et al.*, *ibid.*).

Cropropamide

Respiratory Stimulant

Synonym. It is an ingredient of Prethcamide which is a mixture of equal parts by weight of cropropamide and crotethamide.

Proprietary Names. It is an ingredient of Micoren and of Respirot.

NN-Dimethyl-2-(*N*-propylcrotonamido)butyramide

$\text{C}_{13}\text{H}_{24}\text{N}_2\text{O}_2 = 240.3$

CAS—633-47-6 (cropropamide); 8015-51-8 (prethcamide)

A liquid.

Miscible with water, ethanol, and ether.

Thin-layer Chromatography. *System TA*—Rf 64; *system TB*—Rf 29; *system TC*—Rf 69. (*Acidified potassium permanganate solution*, positive.)

Gas Chromatography. *System GA*—RI 1738.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1654, 1617, 1219, 1282, 1098, 1123 (KBr disk).

Dose. Prethcamide (cropropamide and crotethamide) is usually given in doses of 1.2 to 1.6 g daily.

Crotamiton

Acaricide/Antipruritic

Proprietary Names. Crotamitex; Eurax; Euraxil.

N-Ethylcrotono-*o*-toluidide

$\text{C}_{13}\text{H}_{17}\text{NO} = 203.3$

CAS—483-63-6

A colourless or pale yellow, oily liquid.

Soluble 1 in 400 of water; miscible with ethanol, ether, and methanol.

Thin-layer Chromatography. *System TA*—Rf 83. (*Acidified iodoplatinate solution*, positive.)

Gas Chromatography. *System GA*—RI 1550.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1656, 1623, 1235, 1280, 1316, 1590 (thin film).

Use. Topically in a concentration of 10%.

Crotethamide

Respiratory Stimulant

Synonyms. Crotetamide. It is an ingredient of Prethcamide which is a mixture of equal parts by weight of cropropamide and crotethamide.

Proprietary Names. It is an ingredient of Micoren and of Respirot.

2-(*N*-Ethylcrotonamido)-*NN*-dimethylbutyramide

$\text{C}_{12}\text{H}_{22}\text{N}_2\text{O}_2 = 226.3$

CAS—6168-76-9 (crotethamide); 8015-51-8 (prethcamide)

A liquid.

Miscible with water, ethanol, and ether.

Thin-layer Chromatography. System TA—Rf 61; system TB—Rf 28; system TC—Rf 67. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. System GA—RI 1688.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1655, 1617, 1234, 1098, 1282, 1123 (KBr disk).

Dose. See under Cropropamide.

Cyanocobalamin

Haemopoietic Vitamin

Synonyms. Cobamin; Cycobemin; Vitamin B₁₂.

Proprietary Names. Anacobin; Bedoz; Berubigen; Betalin 12; Bio-12; Cyanabin; Cytacon; Cytamen; Hepacon-B12; Neo-Rubex; Redisol; Rubesol; Rubion; Rubramin; Ruvite; Sytobex. It is an ingredient of Ce-Cobalin, Hepanorm, and Reactivan.

Co α -[α -(5,6-Dimethylbenzimidazolyl)]-C β -cyanocobamide

C₆₃H₈₈CoN₁₄O₁₄P = 1355

CAS—68-19-9

Dark red hygroscopic crystals or powder.

Soluble 1 in 80 of water and 1 in 180 of ethanol (90%); practically insoluble in chloroform and ether.

Ultraviolet Spectrum. Water—278 nm (A_1^1 = 119 a), 361 nm (A_1^1 = 207 a), 550 nm (A_1^1 = 63 a).

Infra-red Spectrum. Principal peaks at wavenumbers 1660, 1497, 1575, 1070, 1150, 1220 (KBr disk).

Dose. Initially 0.25 to 1 mg intramuscularly, on alternate days.

Cyclandelate

Vasodilator

Proprietary Names. Cyclobral; Cyclospasmol; Spasmocyclon.

3,3,5-Trimethylcyclohexyl mandelate

C₁₇H₂₄O₃ = 276.4

CAS—456-59-7

A white amorphous powder, which may sublime on storage into a crystalline form resembling cotton wool. M.p. below 60°.

Practically **insoluble** in water; soluble 1 in about 1 of ethanol; very soluble in ether.

Colour Tests. Liebermann's Test—orange; Marquis Test—orange (slow).

Thin-layer Chromatography. System TD—Rf 74; system TE—Rf 81; system TF—Rf 71.

Gas Chromatography. System GA—RI 1903.

Ultraviolet Spectrum. Methanol—252 nm, 258 nm (A_1^1 = 7.6 b), 264 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1734, 1192, 1212, 1274, 1104, 1074 (KBr disk).

Mass Spectrum. Principal peaks at m/z 107, 69, 125, 83, 79, 55, 41, 77.

Dose. 1.6 g daily.

Cyclazocine

Narcotic Antagonist

3-Cyclopropylmethyl-1,2,3,4,5,6-hexahydro-6,11-dimethyl-2,6-methano-3-benzazocin-8-ol

C₁₈H₂₅NO = 271.4

CAS—3572-80-3

Crystals. M.p. 201° to 204°.

Soluble in chloroform and dilute acetic acid.

Partition Coefficient. Log *P* (octanol/pH 7.4), 1.3.

Colour Tests. Liebermann's Test—black; Mandelin's Test—green; Marquis Test—brown → green.

Thin-layer Chromatography. System *TA*—Rf 53; system *TB*—Rf 15; system *TC*—Rf 13. (Acidified iodoplatinate solution, strong reaction.)

High Pressure Liquid Chromatography. System *HA*—*k'* 2.1.

Ultraviolet Spectrum. Aqueous acid—277 nm; aqueous alkali—237 nm, 298 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1570, 1255, 1304, 754, 1227, 1241 (KBr disk).

Mass Spectrum. Principal peaks at *m/z* 230, 271, 55, 256, 164, 270, 71, 124.

Quantification. GAS CHROMATOGRAPHY. In urine: cyclazocine and norcyclazocine, sensitivity 40 ng, FID—R. F. Kaiko and C. E. Inturrisi, *J. Chromat.*, 1974, 100, 63–72.

GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma: comparison with radioimmunoassay, detection limits 110 pg/ml and 20 pg/ml respectively—J. E. Peterson *et al.*, *J. pharm. Sci.*, 1979, 68, 1447–1450.

Disposition in the Body. Absorbed after oral administration. About 20% of a dose is excreted in the urine unchanged together with 24% as conjugated cyclazocine, 4% as norcyclazocine, and 11% as conjugated norcyclazocine.

Dose. Cyclazocine has been given in maintenance doses of about 4 mg daily; doses of 10 mg have been given to extend the effect to 48 hours.

Cyclizine

Antihistamine/Anti-emetic

1-Benzhydryl-4-methylpiperazine

$C_{18}H_{22}N_2 = 266.4$

CAS—82-92-8

A white or creamy-white crystalline powder. M.p. 106° to 109°. Practically **insoluble** in water; soluble 1 in 6 of ethanol, 1 in 1 of chloroform, and 1 in 6 of ether.

Cyclizine Hydrochloride

Synonym. Cyclizinium Chloride

Proprietary Names. Mareline (tablets); Marzine; Valoid (tablets). It is an ingredient of Diconal, Migril, and Wellconal.

$C_{18}H_{22}N_2 \cdot HCl = 302.8$

CAS—303-25-3

A white crystalline powder, or small colourless crystals. M.p. about 285°, with decomposition.

Soluble 1 in about 125 of water, 1 in about 120 of ethanol, and 1 in 75 of chloroform; practically insoluble in ether.

Cyclizine Lactate

Proprietary Names. Mareline (injection); Valoid (injection).

$C_{18}H_{22}N_2 \cdot C_3H_5O_3 = 356.5$

CAS—5897-19-8

Freely **soluble** in water.

Dissociation Constant. pK_a 2.4, 7.8.

Colour Tests. Liebermann's Test—orange; Marquis Test—yellow.

Thin-layer Chromatography. System *TA*—Rf 57; system *TB*—Rf 49; system *TC*—Rf 41. (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, yellow.)

Gas Chromatography. System *GA*—cyclizine RI 2020, norcyclizine RI 2050; system *GB*—RI 2081; system *GC*—RI 2348; system *GF*—RI 2320.

High Pressure Liquid Chromatography. System *HA*—cyclizine *k'* 2.9, norcyclizine *k'* 2.2.

Ultraviolet Spectrum. Aqueous acid—257 nm, 262 nm ($A_1^1 = 28$ a), 268 nm; aqueous alkali—260 nm ($A_1^1 = 16$ b). (See below)

Infra-red Spectrum. Principal peaks at wavenumbers 716, 756, 701, 984, 1125, 1496 (cyclizine hydrochloride, KBr disk). (See below)

Mass Spectrum. Principal peaks at *m/z* 99, 56, 167, 207, 194, 266, 195, 165.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: cyclizine and norcyclizine, sensitivity 10 ng/ml for cyclizine, AFID—G. Land *et al.*, *J. Chromat.*, 1981, 222; *Biomed. Appl.*, 11, 135–140. In blood or urine: sensitivity 10 ng/ml and 5 ng/ml,

respectively, AFID—D. S. Griffin and R. C. Baselt. *J. analyt. Toxicol.*, 1984, 8, 97–99.

Disposition in the Body. Cyclizine is extensively metabolised by *N*-demethylation to form norcyclizine, a metabolite which is widely distributed throughout the tissues and especially in lungs, kidneys, liver, and spleen. After a dose of 50 mg of cyclizine thrice daily, 1 to 1.8 mg of norcyclizine is excreted in the urine in 4 days.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 50 mg of cyclizine hydrochloride to 1 subject, a peak blood concentration of 0.069 µg/ml was attained in 2 hours (D. S. Griffin and R. C. Baselt, *ibid.*).

On the first day after termination of therapy with oral doses of 50 mg thrice daily to 4 subjects, plasma concentrations of norcyclizine were in the range of 0.004 to 0.022 µg/ml (mean 0.014) (R. Kuntzman *et al.*, *J. Pharmac. exp. Ther.*, 1967, 158, 332–339).

TOXICITY.

In a fatality attributed principally to cyclizine, postmortem concentrations were: blood 15 µg/ml, liver 108 µg/g; doxepin was also detected at concentrations of 0.7 µg/ml and 6 µg/g in the blood and liver, respectively (J. F. Lewin *et al.*, *Bull. int. Ass. forens. Toxicol.*, 1981, 16(2), 23–24).

For case histories involving the injection of cyclizine with dipipanone, see under Dipipanone.

HALF-LIFE. Plasma half-life, cyclizine about 24 hours.

PROTEIN BINDING. In plasma, norcyclizine about 60%.

Dose. Up to 150 mg of cyclizine hydrochloride daily.

Cyclobarbitone

Barbiturate

Synonyms. Cyclobarbitol; Ethylhexabital; Hexemalum.

Note. The name cyclobarbitol has been applied to hexobarbitone.

5-(Cyclohex-1-enyl)-5-ethylbarbituric acid

$C_{12}H_{16}N_2O_3 = 236.3$

CAS—52-31-3

A white crystalline powder, which gradually decomposes on storage. M.p. 171° to 175°.

Soluble 1 in 800 of water, 1 in 4 of ethanol, 1 in 20 of chloroform, and 1 in 15 of ether.

Cyclobarbitone Calcium

Synonym. Hexemalcalcium

Proprietary Names. Phanodorm. It is an ingredient of Evidorm.

$(C_{12}H_{15}N_2O_3)_2Ca = 510.6$

CAS—143-76-0

A white or slightly yellowish, crystalline powder.

Soluble 1 in 100 of water; very slightly soluble in ethanol; practically insoluble in chloroform and ether.

Dissociation Constant. pK_a 7.6 (20°).

Partition Coefficient. Log *P* (octanol/pH 7.4), 1.8.

Colour Tests. Koppanyi–Zwikker Test—violet; Mercurous Nitrate—black; Vanillin Reagent—brown-red/green.

Thin-layer Chromatography. System TD—Rf 50; system TE—Rf 35; system TF—Rf 64; system TH—Rf 59. (Mercuric chloride–diphenylcarbazone reagent, positive; mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown; Zwikker's reagent, pink.)

Gas Chromatography. System GA—cyclobarbitone RI 1963, ketocyclobarbitone RI 2190; system GF—RI 2825.

High Pressure Liquid Chromatography. System HG— k' 5.25; system HH— k' 2.61.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—239 nm ($A_1' = 410$ a); M sodium hydroxide (pH 13)—256 nm ($A_1' = 320$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1693, 1725, 1745, 1300, 1210, 830 (KBr disk).

Mass Spectrum. Principal peaks at m/z 207, 141, 81, 79, 67, 80, 41, 77.

Quantification. See under Amylobarbitone.

Disposition in the Body. Rapidly absorbed after oral administration. The main metabolic reaction appears to be oxidation to ketocyclobarbitone [5-(3-oxocyclohex-1-enyl)-5-ethylbarbituric acid]. Less than 10% of a dose is excreted in the urine unchanged.

THERAPEUTIC CONCENTRATION. In plasma, usually in the range 2 to 10 µg/ml.

After a single oral dose of 300 mg of the calcium salt, given to 6 subjects, peak plasma concentrations of 7.4 to 10.3 µg/ml (mean 8.7) were attained

Cyclobenzaprine

Muscle Relaxant

Synonyms. CBZ; Proheptatriene.

3-(5*H*-Dibenzo[*a,d*]cyclohepten-5-ylidene)-*NN*-dimethylpropylamine

$C_{20}H_{21}N = 275.4$

CAS—303-53-7

Cyclobenzaprine Hydrochloride

Proprietary Name. Flexeril

$C_{20}H_{21}N \cdot HCl = 311.9$

CAS—6202-23-9

A white crystalline powder. M.p. 215° to 219°.

Freely **soluble** in water and ethanol; slightly soluble in chloroform.

Ultraviolet Spectrum. Aqueous acid—290 nm ($A_1^1 = 407$ b). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 764, 778, 800, 968, 988, 880 (KBr disk). (See below)

Mass Spectrum. Principal peaks at m/z 58, 59, 42, 215, 202, 57, 189, 43.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 10 ng/ml, FID—H. B. Hucker and S. C. Stauffer, *J. pharm. Sci.*, 1976, 65, 1253–1255. In plasma: sensitivity 2 ng/ml, AFID—H. B. Hucker and S. C. Stauffer, *J. Chromat.*, 1976, 124, 164–168.

Disposition in the Body. Irregularly absorbed after oral administration, and extensively metabolised. The major metabolites are a glucuronide conjugate and 10,11-dihydroxynortriptyline; monodesmethylcyclobenzaprine is a minor metabolite. About 50% of an oral dose is excreted in the urine in 5 days, with less than 1% as unchanged drug. About 14% of a dose is eliminated in the faeces.

in 0.7 to 2.5 hours (D. D. Breimer and A. C. M. Winten, *Eur. J. clin. Pharmac.*, 1976, 9, 443–450).

TOXICITY. The estimated minimum lethal dose is 2 g. Severe toxic effects are associated with blood concentrations greater than 10 µg/ml.

HALF-LIFE. Plasma half-life, 8 to 17 hours (mean 12), increased in subjects with liver disease.

VOLUME OF DISTRIBUTION. About 0.5 litre/kg.

CLEARANCE. Plasma clearance, about 0.5 ml/min/kg.

PROTEIN BINDING. In plasma, about 70%.

Dose. 100 to 400 mg of cyclobarbitone calcium, as a hypnotic.

**THERAPEUTIC CONCENTRATION.**

After a single oral dose of 40 mg to 4 subjects, peak plasma concentrations of about 0.027 μg/ml were attained in 4 hours; following oral doses of 20 mg three times a day to 9 subjects, a mean peak plasma concentration of 0.034 μg/ml was reported 6 hours after the first dose on the fourth day (H. B. Hucker *et al.*, *J. clin. Pharmac.*, 1977, 17, 719-727).

TOXICITY.

In a fatality where cyclobenzaprine was the suspected cause of death, the following postmortem tissue concentrations were reported: blood 0.46 μg/ml, bile 12.0 μg/ml, liver 12.4 μg/g, urine 3.2 μg/ml; low concentrations of morphine and diazepam were also detected (B. K. Beck and T. Lamoreaux, *Bull. int. Ass. forens. Toxicol.*, 1979, 14(3), 27).

HALF-LIFE. Plasma half-life, about 1 to 3 days.

PROTEIN BINDING. In plasma, about 93%.

Dose. Usually 30 mg of cyclobenzaprine hydrochloride daily; maximum of 60 mg daily.

Cyclofenil*Induction of Ovulation*

Proprietary Names. Fertodur; Ondogyne; Ondonid; Rehibin; Sexovid.

4,4'-(Cyclohexyldienemethylene)bis(phenyl acetate)

$C_{23}H_{24}O_4 = 364.4$

CAS—2624-43-3

A white crystalline powder. M.p. 137° to 140°.

Practically **insoluble** in water; soluble 1 in 250 of ethanol, 1 in 2 of chloroform, and 1 in 30 of ether.

Ultraviolet Spectrum. Acid ethanol—247 nm; alkaline ethanol—262 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1204, 1219, 1754, 917, 1162, 1492.

Dose. 200 to 400 mg daily; doses of 800 mg daily have been given in 5-day courses.

Cycloguanil*Antimalarial*

1-(4-Chlorophenyl)-1,2-dihydro-2,2-dimethyl-1,3,5-triazine-4,6-diamine

$C_{11}H_{14}ClN_5 = 251.7$

CAS—516-21-2

Crystals. M.p. 146°.

Cycloguanil Embonate

Synonym. Cycloguanil Pamoate

$C_{11}H_{14}ClN_5 \cdot \frac{1}{2}(C_{23}H_{16}O_6) = 445.9$

CAS—609-78-9

A pale greenish-yellow, crystalline powder. M.p. 231° to 234°.

Practically **insoluble** in water; sparingly soluble in dimethylformamide.

Ultraviolet Spectrum. Methanol—237 nm ($A_1^1 = 2250$ b), 278 nm, 289 nm ($A_1^1 = 180$ b), 301 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1673, 1515, 1628, 1570, 760, 1224 (KBr disk).

Ultraviolet Spectrum. Aqueous acid—261 nm ($A_1^1 = 508$ a).

Quantification. See under Proguanil.

Disposition in the Body. Slowly absorbed after intramuscular administration and excreted mainly in the urine. Cycloguanil is the active metabolite of proguanil.

Dose. The equivalent of 5 to 6 mg/kg of cycloguanil, intramuscularly, every 4 months.

Cyclomethycaine

Local Anaesthetic

3-(2-Methylpiperidino)propyl 4-cyclohexyloxybenzoate

$C_{22}H_{33}NO_3 = 359.5$

CAS—139-62-8

A white crystalline powder.

Sparingly **soluble** in water, ethanol, and ether; very slightly soluble in chloroform.

Cyclomethycaine Sulphate

Proprietary Name. Surfacaine

$C_{22}H_{33}NO_3 \cdot H_2SO_4 = 457.6$

CAS—50978-10-4

A white crystalline powder. M.p. 162° to 166°.

Soluble 1 in 50 of water, 1 in 50 of ethanol, and 1 in about 227 of chloroform.

Colour Test. Mandelin's Test—green → brown.

Thin-layer Chromatography. *System TA*—Rf 58; *system TB*—Rf 55; *system TC*—Rf 36; *system TL*—Rf 25. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. *System HR*— k' 10.31.

Infra-red Spectrum. Principal peaks at wavenumbers 1704, 1605, 1253, 775, 1170, 1235 (cyclomethycaine sulphate, Nujol mull).

Mass Spectrum. Principal peaks at m/z 112, 344, 121, 41, 67, 55, 54, 345.

Use. Cyclomethycaine sulphate has been used in concentrations of 0.5 to 1%.

Cyclopentamine

Sympathomimetic

Synonym. Cyclopentadrin

2-Cyclopentyl-1,*N*-dimethylethylamine

$C_9H_{19}N = 141.3$

CAS—102-45-4

Cyclopentamine Hydrochloride*Synonym.* Cyclopentaminium Chloride*Proprietary Name.* It is an ingredient of Co-Pyrnil. $C_9H_{19}N, HCl = 177.7$ *CAS*—538-02-3

A white crystalline powder. M.p. 111° to 117°.

Soluble 1 in 1 of water, 1 in 2 of ethanol, and 1 in 1 of chloroform; slightly soluble in ether.**Thin-layer Chromatography.** *System TA*—Rf 20; *system TB*—Rf 32; *system TC*—Rf 10. (*Dragendorff spray*, positive; *acidified iodoplatinate solution*, positive; *ninhydrin spray*, positive; *acidified potassium permanganate solution*, positive.)**Gas Chromatography.** *System GA*—RI 1087; *system GB*—RI 1095.**High Pressure Liquid Chromatography.** *System HA*—k' 1.7.**Ultraviolet Spectrum.** No significant absorption, 230 to 360 nm.**Infra-red Spectrum.** Principal peaks at wavenumbers 1585, 1020, 1050, 1100, 1082, 1158.**Mass Spectrum.** Principal peaks at m/z 58, 41, 30, 126, 59, 69, 56, 44.**Disposition in the Body.****TOXICITY.** The estimated minimum lethal dose for children up to 2 years is 200 mg when applied to the mucous membranes; the minimum lethal dose for adults may be at least 10 times greater.**Dose.** Cyclopentamine hydrochloride has been used as a 0.5 or 1% nasal solution. It has been given in doses of 25 mg intramuscularly, or 5 to 10 mg intravenously.**Cyclopenthiazide***Diuretic**Proprietary Names.* Navidrex. It is an ingredient of Trasidrex.

6-Chloro-3-cyclopentylmethyl-3,4-dihydro-2H-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxide

 $C_{13}H_{18}ClN_3O_4S_2 = 379.9$ *CAS*—742-20-1

A white powder. M.p. 235°, with decomposition.

Practically **insoluble** in water; soluble 1 in 12 of ethanol and 1 in 600 of chloroform; soluble in ether.**Colour Tests.** Koppányi-Zwicker Test—violet; Liebermann's Test—brown-green; Sulphuric Acid—yellow.**Thin-layer Chromatography.** *System TD*—Rf 21; *system TE*—Rf 66; *system TF*—Rf 62.**High Pressure Liquid Chromatography.** *System HN*—k' 16.45.**Ultraviolet Spectrum.** Aqueous acid—274 nm ($A_1^1 = 556$ a), 319 nm. No alkaline shift.**Infra-red Spectrum.** Principal peaks at wavenumbers 1168, 1138, 1605, 1309, 1511, 1060 (KBr disk).**Mass Spectrum.** Principal peaks at m/z 296, 41, 44, 110, 298, 285, 55, 268.**Dose.** 250 to 500 µg daily; maximum of 1.5 mg daily.**Cyclopentobarbitone***Barbiturate**Synonyms.* Cyclopentenylallyl Barbituric Acid; Cyclopentobarbital.*Proprietary Name.* Cyclopal

5-Allyl-5-(cyclopent-2-enyl)barbituric acid

 $C_{12}H_{14}N_2O_3 = 234.3$ *CAS*—76-68-6

Crystals. M.p. 139° to 140°.

Slightly **soluble** in cold water; more soluble in hot water; freely soluble in ethanol.**Colour Test.** Vanillin Reagent—brown-red/green.**Thin-layer Chromatography.** *System TD*—Rf 50; *system TE*—Rf 37; *system TF*—Rf 64; *system TH*—Rf 62.**Gas Chromatography.** *System GA*—RI 1862.

High Pressure Liquid Chromatography. System HG— k' 6.00; system HH— k' 3.84.

Ultraviolet Spectrum. Borax buffer 0.05M (pH 9.2)—241 nm ($A_1^1=411$ a); M sodium hydroxide (pH 13)—254 nm ($A_1^1=306$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1700, 1755, 1212, 815, 1319, 848 (KBr disk).

Mass Spectrum. Principal peaks at m/z 67, 193, 66, 41, 169, 39, 65, 77.

Dose. Cyclopentobarbitone has been given in a dose of 100 to 200 mg.

Cyclopentolate

Anticholinergic

2-Dimethylaminoethyl 2-(1-hydroxycyclopentyl)-2-phenylacetate

$C_{17}H_{25}NO_3=291.4$

CAS—512-15-2

Cyclopentolate Hydrochloride

Proprietary Names. Cyclogyl; Cyclophen; Mydplegic; Mydrilate; Skiacol P.O.S.; Zyklotat.

$C_{17}H_{25}NO_3 \cdot HCl=327.9$

CAS—5870-29-1

A white crystalline powder. M.p. 135° to 138°.

Soluble 1 in less than 1 of water and 1 in 5 of ethanol; practically insoluble in ether.

Dissociation Constant. pK_a 7.9.

Colour Test. Mandelin's Test—brown.

Thin-layer Chromatography. System TA—Rf 57; system TB—Rf 27; system TC—Rf 39.

Gas Chromatography. System GA—RI 2020.

High Pressure Liquid Chromatography. System HA— k' 1.6 (tailing peak).

Ultraviolet Spectrum. Aqueous acid—252 nm ($A_1^1=5$ a), 258 nm ($A_1^1=6$ a), 264 nm ($A_1^1=5$ a). No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1148, 1733, 704, 1199, 735, 990 (cyclopentolate hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 58, 71, 72, 207, 42, 91, 59, 118.

Use. Cyclopentolate hydrochloride is used as a 0.5 to 1% ophthalmic solution.

Cyclophosphamide

Antineoplastic

Proprietary Names. Cytoxan; Endoxan(a); Procytox; Sendoxan. 2-[Bis(2-chloroethyl)amino]perhydro-1,3,2-oxazaphosphorine 2-oxide monohydrate

$C_7H_{15}Cl_2N_2O_2P \cdot H_2O=279.1$

CAS—50-18-0 (anhydrous); 6055-19-2 (monohydrate)

A fine, white, crystalline powder which discolours on exposure to light. M.p. 49° to 53°. It liquefies upon loss of its water of crystallisation. In aqueous solutions, at temperatures above 30°, hydrolysis occurs with removal of chlorine.

Soluble 1 in 25 of water and 1 in 1 of ethanol; slightly soluble in ether.

Colour Test. Phosphorus Test—yellow precipitate.

Gas Chromatography. System GA—RI 2191.

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1225, 1044, 975, 1088, 945, 1128 (KBr disk). (See below)

Quantification. GAS CHROMATOGRAPHY. In plasma: sensitivity 10 ng/ml, AFID—N. Van den Bosch and D. De Vos, *J. Chromat.*, 1980, 183; *Biomed. Appl.*, 9, 49–56. In plasma or urine: detection limit 10 ng/ml, AFID—T. Facchinetti *et al.*, *J. Chromat.*, 1978, 145; *Biomed. Appl.*, 2, 315–318. In plasma:

cyclophosphamide metabolites (phosphoramidate mustard and normitrogen mustard), AFID—F. D. Juma *et al.*, *Br. J. clin. Pharmacol.*, 1980, 10, 327–335.

HIGH PRESSURE LIQUID CHROMATOGRAPHY–MASS SPECTROMETRY. In urine: cyclophosphamide, 4-ketocyclophosphamide and carboxyphosphamide, detection limit 10 pg—U. Bahr and H.-R. Schulten, *Biomed. Mass Spectrom.*, 1981, 8, 553–557.

Disposition in the Body. Well absorbed after oral administration; bioavailability greater than 75%. The parent drug is inactive, but is converted into active metabolites by the liver. The drug and metabolites are widely distributed in the body. It is oxidised to 4-hydroxycyclophosphamide, which is in equilibrium with aldophosphamide, both of which are cytotoxic. 4-Hydroxycyclophosphamide can be oxidised further to 4-ketocyclophosphamide (inactive). Aldophosphamide may be converted to the cytotoxic metabolites phosphoramidate mustard and acrolein, or oxidised to inactive carboxyphosphamide. Carboxyphosphamide may be converted to normitrogen mustard, an active alkylating agent at acid pH. Up to 95% of a dose is excreted in the urine, mostly during the first 48 hours, with up to 25% as unchanged drug and the rest as metabolites. Small amounts are excreted in the bile and faeces.

THERAPEUTIC CONCENTRATION.

After a single intravenous dose of 9.4 mg/kg to a patient, a plasma concentration of about 26 µg/ml of cyclophosphamide was attained immediately after injection, and this fell to about 13 µg/ml after 2 hours. After single intravenous doses of 9 to 12 mg/kg and 40 mg/kg, peak plasma concentrations of unbound alkylating metabolites of about 0.3 to 2 µg/ml (8 studies) and about 2 to 6 µg/ml (7 studies), respectively, were achieved, usually after 2 to 3 hours (C. M. Bagley, jun., *et al.*, *Cancer Res.*, 1973, 33, 226–233).

HALF-LIFE. Plasma half-life, about 3 to 12 hours (mean 7).

VOLUME OF DISTRIBUTION. About 0.7 litre/kg.

CLEARANCE. Plasma clearance, about 1 ml/min/kg.

SALIVA. Plasma: saliva ratio, about 1.6.

PROTEIN BINDING. In plasma, cyclophosphamide about 12 to 24%, alkylating metabolites about 50 to 60%.

NOTE. For a review of the pharmacokinetics of cyclophosphamide, see L. B. Grochow and M. Colvin, *Clin. Pharmacokinet.*, 1979, 4, 380–394.

Dose. Regimens usually range from 2 to 6 mg/kg daily, by mouth or intravenously, to 60 to 80 mg/kg as a single intravenous dose every 3 to 4 weeks.

Cycloserine

Antibiotic/Tuberculostatic

Synonym. D-Cycloserine

Proprietary Names. Closina; Seromycin.

(R)-4-Aminoisoxazolidin-3-one

$C_3H_6N_2O_2 = 102.1$

CAS—68-41-7

An antimicrobial substance produced by the growth of certain strains of *Streptomyces orchidaceus* or *S. garyphalus*, or obtained by synthesis.

A white or pale yellow, hygroscopic, crystalline powder. It is unstable in neutral or acid solutions. M.p. 153° to 155°.

Soluble 1 in 10 of water and 1 in 50 of ethanol; slightly soluble in chloroform and ether.

Dissociation Constant. pK_a 4.5, 7.4 (25°).

Colour Test. Mercurous Nitrate—black.

Thin-layer Chromatography. System TA—Rf 44; system TB—Rf 01; system TC—Rf 01. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1577, 1550, 1526, 1620, 934, 877 (KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 29, 28, 59, 30, 42, 74, 102.

Disposition in the Body. Readily absorbed after oral administration and widely distributed throughout body fluids and tissues. About 65% of a dose is excreted in the urine unchanged in 72 hours, mostly in the first 24 hours.

THERAPEUTIC CONCENTRATION.

After oral administration of 750 mg, divided into three 6-hourly doses to 11 subjects, followed by a single dose of 500 mg the next morning, peak serum concentrations of 22 to 34 µg/ml (mean 28) were reported 2 to 4 hours after the last dose (M. J. Mattila *et al.*, *Scand. J. resp. Dis.*, 1969, 50, 291–300).

TOXICITY.

A female subject who ingested a non-fatal overdose of 3 g, had a peak plasma concentration of 91 µg/ml on admission to hospital; following peritoneal dialysis for 20 hours, the plasma concentration declined to 25 µg/ml (R. Atkins *et al.*, *Br. med. J.*, 1965, 1, 907–908).

HALF-LIFE. Plasma half-life, 4 to 30 hours (mean 10).

PROTEIN BINDING. In plasma, less than 20%.

Dose. 0.25 to 1 g daily.

Cyclothiazide

Diuretic

Proprietary Names. Anhydron; Doburil.

6-Chloro-3,4-dihydro-3-(norborn-5-en-2-yl)-2H-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxide

$C_{14}H_{16}ClN_3O_4S_2 = 389.9$

CAS—2259-96-3

A white powder. M.p. 217° to 225°.

Practically **insoluble** in water; soluble 1 in 70 of ethanol and 1 in 30 of methanol; freely soluble in acetone; practically insoluble in chloroform and ether.

Colour Tests. Koppanyi-Zwicker Test—violet; Liebermann's Test—brown; Sulphuric Acid—orange → red-brown.

Thin-layer Chromatography. System TA—Rf 77; system TD—Rf 18; system TE—Rf 59; system TF—Rf 60. (Acidified potassium permanganate solution, positive.)

High Pressure Liquid Chromatography. System HN—k' 10.78, 11.91, and 12.81.

Ultraviolet Spectrum. Aqueous acid—272 nm ($A_1^1 = 549$ b), 314 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1596, 1153, 1168, 1307, 1500, 1075 (KBr disk).

Mass Spectrum. Principal peaks at m/z 66, 120, 39, 65, 269, 205, 118, 77.

Dose. 1 to 2 mg daily; up to 6 mg daily may be given.

Cycrimine

Anticholinergic

1-Cyclopentyl-1-phenyl-3-piperidinopropan-1-ol

$C_{19}H_{29}NO = 287.4$

CAS—77-39-4

M.p. 90° to 96°.

Cycrimine Hydrochloride

Synonym. Cycriminium Chloride

Proprietary Name. Pagitane Hydrochloride

$C_{19}H_{29}NO \cdot HCl = 323.9$

CAS—126-02-3

A white solid. M.p. about 242°, with decomposition.

Soluble 1 in 175 of water, 1 in 50 of ethanol, and 1 in 35 of chloroform; practically insoluble in ether.

Colour Tests. Liebermann's Test—red-orange; Mandelin's Test—red-brown; Marquis Test—orange → red.

Thin-layer Chromatography. System TA—Rf 66; system TB—Rf 67; system TC—Rf 61. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System GA—RI 2114.

Ultraviolet Spectrum. Aqueous acid—251 nm, 256 nm ($A_1^1 = 6$ b), 263 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 696, 1117, 755, 751, 1030, 1298 (KBr disk).

Mass Spectrum. Principal peaks at m/z 98, 41, 42, 55, 99, 77, 69, 44.

Dose. Usually 3.75 to 20 mg of cycrimine hydrochloride daily.

Cyproheptadine

Antihistamine

4-(5*H*-Dibenzo[*a,d*]cyclohepten-5-ylidene)-1-methylpiperidine

$C_{21}H_{21}N = 287.4$

CAS—129-03-3

Crystals. M.p. about 113°.

Cyproheptadine Hydrochloride

Proprietary Names. Antegan; Nuran; Periactin(e); Periactinol; Vimicon.
 $C_{21}H_{21}N, HCl, 1\frac{1}{2}H_2O = 350.9$

CAS—969-33-5 (anhydrous); **41354-29-4** (sesquihydrate)

A white to slightly yellow, crystalline powder. M.p. 214° to 216° , with decomposition.

Soluble 1 in 275 of water, 1 in 35 of ethanol, 1 in about 16 of chloroform, and 1 in 1.5 of methanol; practically insoluble in ether.

Partition Coefficient. Log *P* (octanol/pH 7.4), 3.2.

Colour Tests. Mandelin's Test—violet-brown; Marquis Test—grey-green; Sulphuric Acid—violet.

Thin-layer Chromatography. System *TA*—Rf 51; system *TB*—Rf 45; system *TC*—Rf 44. (Acidified iodoplatinate solution, positive.)

Gas Chromatography. System *GA*—RI 2366; system *GC*—RI 2307; system *GF*—RI 2710.

High Pressure Liquid Chromatography. System *HA*—*k'* 3.2.

Ultraviolet Spectrum. Aqueous acid—286 nm ($A_1^1 = 433$ a); aqueous alkali—284 nm ($A_1^1 = 377$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 777, 756, 815, 786, 1640, 960 (cyproheptadine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at *m/z* 287, 96, 286, 215, 70, 44, 58, 42.

Quantification. GAS CHROMATOGRAPHY. In plasma or urine: sensitivity 3 ng/ml, AFID—H. B. Hucker and J. E. Hutt, *J. pharm. Sci.*, 1983, 72, 1069–1070.

Disposition in the Body. Absorbed after oral administration and extensively distributed throughout the tissues. Metabolised by aromatic ring hydroxylation, *N*-demethylation, heterocyclic ring oxidation, and glucuronic acid conjugation; the major metabolite in urine is a quaternary ammonium glucuronide conjugate. About 67 to 77% of a dose is excreted in the urine in 6 days, the remainder being eliminated in the faeces. Of the excreted material, 58 to 65% is conjugated with glucuronic acid, 9 to 11% is conjugated with sulphate, 20 to 26% is excreted as polar material not hydrolysable by glucuronidase or sulphatase, and about 5% is unconjugated.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 5 mg to 2 subjects, peak plasma concentrations of cyproheptadine metabolites of 0.036 and 0.05 µg/ml were attained in 6 to 9 hours; unchanged drug was not detected (K. L. Hintze *et al.*, *Drug Met. Disp.*, 1975, 3, 1–9).

Dose. 12 to 16 mg of anhydrous cyproheptadine hydrochloride daily; maximum of 32 mg daily.

Cytarabine

Antineoplastic

Synonyms. Arabinosylcytosine; Ara-C; Cytosine Arabinoside.

Proprietary Names. Alexan; Aracytin(e); Cytosar; Cytosar-U; Udicil.

4-Amino-1-β-D-arabinofuranosylpyrimidin-2(1*H*)-one

$C_9H_{13}N_3O_5 = 243.2$

CAS—147-94-4

A white crystalline powder. M.p. 212° to 213° .

Soluble 1 in 10 of water, 1 in 1000 of ethanol, and 1 in 1000 of chloroform.

Cytarabine Hydrochloride

$C_9H_{13}N_3O_5, HCl = 279.7$

CAS—69-74-9

A white crystalline powder.

Soluble 1 in 1 of water; less soluble in organic solvents.

Dissociation Constant. pK_a 4.3.

Thin-layer Chromatography. System *TA*—Rf 05; system *TB*—Rf 00; system *TC*—Rf 01. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—280 nm ($A_1^1 = 555$ a); aqueous alkali—274 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1075, 1027, 1145, 1109, 1178, 1002 (KBr disk).

Quantification. GAS CHROMATOGRAPHY. In plasma: detection limit 40 ng/ml, AFID—J. Boutagy and D. J. Harvey, *J. Chromat.*, 1978, 146; *Biomed. Appl.*, 3, 283–296.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma: detection limit 20 ng/ml, UV detection—R. W. Bury and P. J. Keary, *ibid.*, 350–353. In plasma, urine, or cerebrospinal fluid: detection limit 20 ng/ml, UV detection—J. A. Sinkule and W. E. Evans, *J. Chromat.*, 1983, 274; *Biomed. Appl.*, 25, 87–93.

Dose. 2 to 4 mg/kg daily, intravenously.

Cytisine

Alkaloid

Synonyms. Baptitoxine; Cytiton; Laburnine; Sophorine; Ulexine.

1,2,3,4,5,6-Hexahydro-1,5-methano-8H-pyrido[1,2-a][1,5]diazocin-8-one

$C_{11}H_{14}N_2O = 190.2$

CAS—485-35-8

An alkaloid found in all parts of the laburnum, *Laburnum anagyroides* (Leguminosae), particularly in the pods and seeds, and in some other leguminous plants.

A white or slightly yellowish, crystalline powder. M.p. 154° to 157°.

Soluble 1 in 1.3 of water, 1 in 3.5 of ethanol, and 1 in 2 of chloroform.

Thin-layer Chromatography. System TA—Rf 40; system TB—Rf 01; system TC—Rf 10. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—232 nm, 302 nm ($A_1^1 = 344$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1650, 1540, 1565, 1140, 790, 1311 (KBr disk).

Mass Spectrum. Principal peaks at m/z 44, 146, 147, 39, 41, 190, 42, 148.

Quantification. ULTRAVIOLET SPECTROPHOTOMETRY. In blood—H. G. H. Richards and A. Stephens, *Medicine, Sci. Law*, 1970, 10, 260–266.

Disposition in the Body.

TOXICITY. Cytisine is a highly toxic alkaloid which resembles nicotine in its actions. Fatalities have occurred after the ingestion of laburnum seeds, but recovery is more usual.

In a fatality due to the ingestion of laburnum seeds (estimated amount ingested 50 mg), a blood concentration of 6.8 $\mu\text{g/ml}$ of cytisine was reported; the stomach contained 23 laburnum pods (H. G. H. Richards and A. Stephens, *ibid.*).

NOTE. For reviews of laburnum poisoning in children see R. G. Mitchell, *Lancet*, 1951, 2, 57–58, and A. Bramley and R. Goulding, *Br. med. J.*, 1981, 283, 1220–1221.

Danthron

Purgative

Synonyms. Antrapurol; Chrysazin; Chryzacin; Dantron; Dianthon; Dioxanthrachinonum.

Proprietary Names. Dorbane; Duolax; Modane; Roydan. It is an ingredient of Dorbanex, Dorbantyl, Doxidan, Normacol X, and Normax.

1,8-Dihydroxyanthraquinone

$C_{14}H_8O_4 = 240.2$

CAS—117-10-2

An orange crystalline powder. M.p. 190° to 197°.

Practically **insoluble** in water; soluble 1 in 2500 of ethanol, 1 in 30 of chloroform, and 1 in 500 of ether; soluble in solutions of alkali hydroxides.

Colour Test. When dissolved in *sulphuric acid*—red; dilution with water gives a yellow precipitate.

Thin-layer Chromatography. *System TD*—Rf 80; *system TE*—Rf 43; *system TF*—Rf 69.

Ultraviolet Spectrum. Methanol—252 nm ($A_1^1 = 915$ a), 283 nm; alkaline methanol—280 nm ($A_1^1 = 510$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1264, 740, 1620, 1597, 1152, 1197 (KBr disk).

Mass Spectrum. Principal peaks at m/z 240, 212, 241, 184, 138, 92, 128, 63.

Dose. 50 to 150 mg daily.

Dantrolene

Muscle Relaxant

1 - [5 - (4 - Nitrophenyl)furfurylideneamino]imidazolidine - 2,4 - dione

$C_{14}H_{10}N_4O_5 = 314.3$

CAS—7261-97-4

Crystals. M.p. 279° to 280°.
Practically **insoluble** in water.

Dantrolene Sodium

Proprietary Names. Dantamacrin; Dantrium.

$C_{14}H_9N_4NaO_5 \cdot 3\frac{1}{2}H_2O = 399.3$

CAS—14663-23-1 (anhydrous); 24868-20-0 (hemiheptahydrate)

An orange powder.

Slightly **soluble** in water; its solubility increases in alkaline solution. Soluble 1 in 40 to 1 in 50 of acetone, and 1 in 25 of propylene glycol.

Dissociation Constant. pK_a 7.5.

Thin-layer Chromatography. *System TD*—Rf 19; *system TE*—Rf 09; *system TF*—Rf 36.

Ultraviolet Spectrum. Dantrolene sodium: aqueous alkali—314 nm ($A_1^1 = 487$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1600, 1225, 1510, 850, 1713, 1108 (dantrolene sodium, KBr disk).

Quantification. SPECTROFLUORIMETRY. In plasma, blood, urine or tissues: sensitivity 100 ng/ml in plasma, blood and urine, 400 ng/ml in bile and tissues—R. D. Hollifield and J. D. Conklin, *J. pharm. Sci.*, 1973, 62, 271–274.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In plasma or urine: dantrolene, 5-hydroxydantrolene and *p*-acetamidodantrolene, detection limit 20 ng/ml, UV detection—E. W. Wuis *et al.*, *J. Chromat.*, 1982, 231; *Biomed. Appl.*, 20, 401–409.

Disposition in the Body. Slowly and incompletely absorbed after oral administration. Metabolised by oxidation to 5-hydroxydantrolene, which is active, and by reduction followed by acetylation

to form the *p*-acetamido derivative. About 20% of an oral dose is excreted in the urine as metabolites, mainly the 5-hydroxy derivative; less than 5% of a dose is excreted in the urine as unchanged drug; up to about 50% of a dose may be excreted in the bile.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 100 mg to 8 subjects, peak plasma concentrations of 0.7 to 1.7 µg/ml (mean 1.2) of dantrolene and 0.2 to 0.5 µg/ml (mean 0.4) of 5-hydroxydantrolene were attained in about 1 to 8 hours and 1 to 22 hours respectively (W. J. Meyler *et al.*, *Eur. J. clin. Pharmacol.*, 1979, 16, 203–209).

In 4 subjects receiving daily oral doses of 25 to 50 mg 2 to 4 times a day, plasma-dantrolene concentrations were fairly stable and remained between about 0.03 and 0.1 µg/ml; concentrations in an additional 2 subjects fluctuated between about 0.03 and 0.2 µg/ml; plasma concentrations of 5-hydroxydantrolene and *p*-acetamidodantrolene ranged from about 0.1 to 0.3 µg/ml (J. J. Vallner *et al.*, *Curr. ther. Res.*, 1979, 25, 79–91).

TOXICITY. Fatalities due to liver damage have been reported.

HALF-LIFE. Plasma half-life, dantrolene 4 to 22 hours (mean 9), 5-hydroxydantrolene 8 to 29 hours (mean 16).

NOTE. For a review of the pharmacokinetics of dantrolene see R. M. Pinder *et al.*, *Drugs*, 1977, 13, 3–23.

Dose. Initially 25 mg of dantrolene sodium daily, increased to a maximum of 400 mg daily.

Dapsone

Antileprotic

Synonyms. DADPS; DDS; Diaphenylsulfone; Disulone; Sulphonyldianiline.

Proprietary Names. Avlosulfon. It is an ingredient of Maloprim.

Bis(4-aminophenyl) sulphone

$C_{12}H_{12}N_2O_2S = 248.3$

CAS—80-08-0

A white or slightly yellowish-white crystalline powder. It discolours on exposure to light but this is not accompanied by significant decomposition. M.p. 175° to 181°.

Soluble 1 in 7000 of water and 1 in about 36 of ethanol; freely soluble in acetone; soluble in dilute mineral acids.

Dissociation Constant. pK_a 1.3, 2.5.

Gas Chromatography. *System GA*—RI 2880.

Ultraviolet Spectrum. Aqueous acid—288 nm ($A_1^1 = 350$ b); aqueous alkali—256 nm, 292 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1150, 1276, 1592, 1107, 685, 1633 (KBr disk).

Mass Spectrum. Principal peaks at m/z 108, 248, 140, 65, 92, 141, 109, 80.

Quantification. GAS CHROMATOGRAPHY. In plasma: dapsone and monoacetyldapsone, ECD—H. P. Burchfield *et al.*, *Analyt. Chem.*, 1973, 45, 916–920.

HIGH PRESSURE LIQUID CHROMATOGRAPHY. In raw material, dosage forms or biological fluids: detection limit 10 pg using

fluorescence detection and 250 pg using UV detection—C. A. Mannan *et al.*, *J. pharm. Sci.*, 1977, 66, 1618–1623. In plasma: dapsone and monoacetyldapsone, detection limit 5 ng/ml, UV detection—C. R. Jones and S. M. Ovenell, *J. Chromat.*, 1979, 163; *Biomed. Appl.*, 5, 179–185. In serum: dapsone and monoacetyldapsone, sensitivity 200 ng/ml, UV detection—J. Zuidema *et al.*, *J. Chromat.*, 1980, 182; *Biomed. Appl.*, 8, 130–135.

THIN-LAYER CHROMATOGRAPHY. In plasma or saliva: detection limit 20 ng/ml—R. A. Ahmad and H. J. Rogers, *Eur. J. clin. Pharmacol.*, 1980, 17, 129–133.

Disposition in the Body. Slowly and almost completely absorbed after oral administration and widely distributed throughout the body. It is acetylated to monoacetyldapsone, the extent of which is genetically determined. It is also metabolised by *N*-oxidation to mono-*N*-hydroxydapsone, together with glucuronic acid and sulphate conjugation of dapsone and the metabolites. Enterohepatic recycling occurs. About 70 to 90% of a dose is excreted in the urine, about 10 to 20% as unchanged drug, about 50% as dapsone conjugates, and about 30% as *N*-oxidation products (mostly conjugated). Small amounts are eliminated in the faeces. About 30 to 50% of a single dose is excreted in the urine within 24 hours and more than 70% in 3 days, but there is wide individual variation.

THERAPEUTIC CONCENTRATION.

After a single oral dose of 50 mg to 6 subjects, plasma concentrations of dapsone were 1.02 to 1.44 µg/ml (mean 1.24) in 3 slow acetylators, and 1.03 to 1.48 µg/ml (mean 1.23) in 3 rapid acetylators, after 4 hours. The concentrations of monoacetyldapsone were 0.15 to 0.38 µg/ml (mean 0.25) in the slow acetylators and 0.63 to 1.66 µg/ml (mean 0.98) in the rapid acetylators, after 4 hours (J. T. Biggs and L. Levy, *Proc. Soc. exp. Biol. Med.*, 1971, 137, 692–695).

TOXICITY. Toxic effects are likely to occur at serum concentrations above 10 µg/ml.

In 1 case of fatal overdosage, a 22-month-old child died 55 hours after ingesting about 5 g of dapsone. The concentrations in the plasma and cerebrospinal fluid were 150 µg/ml and 33 µg/ml, respectively, 42 hours after ingestion. Postmortem concentrations were: blood 135 µg/ml, brain 90 µg/g, liver 165 µg/g, and urine 400 µg/ml (R. Davies, *Lancet*, 1950, 1, 905–906).

HALF-LIFE. Plasma half-life, 10 to 50 hours (mean 24).

PROTEIN BINDING. In plasma, dapsone 50 to 80%, monoacetyldapsone 98 to 100%.

Dose. 50 to 100 mg daily.

Debrisoquine

Antihypertensive

Synonym. Isocaramidine

1,2,3,4-Tetrahydroisoquinoline-2-carboxamide

 $C_{10}H_{13}N_3 = 175.2$

CAS—1131-64-2

**Debrisoquine Sulphate**

Proprietary Name. Declinax

 $(C_{10}H_{13}N_3)_2 \cdot H_2SO_4 = 448.5$

CAS—581-88-4

A white crystalline powder. M.p. about 274°, with decomposition.

Soluble 1 in 40 of water; very slightly soluble in ethanol; practically insoluble in chloroform and ether.**Dissociation Constant.** pK_a 11.9.**Colour Tests.** Mandelin's Test—green; Marquis Test—red-brown.**Thin-layer Chromatography.** System TA—Rf 01; system TB—Rf 00; system TC—Rf 00. (Acidified iodoplatinate solution, positive.)**Gas Chromatography.** System GA—not eluted.**High Pressure Liquid Chromatography.** System HA— k' 1.2.**Ultraviolet Spectrum.** Aqueous acid—262 nm ($A_1^1 = 17.7$ a), 270 nm. No alkaline shift.**Infra-red Spectrum.** Principal peaks at wavenumbers 1614, 1090, 1650, 1583, 750, 715 (debrisoquine sulphate, KBr disk).**Mass Spectrum.** Principal peaks at m/z 132, 104, 44, 175, 103, 117, 43, 130.**Quantification.** GAS CHROMATOGRAPHY. In blood, plasma, saliva or urine: debrisoquine and 4-hydroxydebrisoquine, sensitivity 3 ng/ml, AFID—M. S. Lennard *et al.*, *J. Chromat.*, 1977, 133, 161–166. In urine: ECD—J. R. Idle *et al.*, *Br. J. clin. Pharmacol.*, 1979, 7, 257–266.GAS CHROMATOGRAPHY–MASS SPECTROMETRY. In plasma: sensitivity 1 ng/ml for debrisoquine and 5 ng/ml for 4-hydroxydebrisoquine—S. L. Malcolm and T. R. Marten, *Analyt. Chem.*, 1976, 48, 807–809.**Disposition in the Body.** Rapidly absorbed after oral administration. The main metabolic reaction is 4-hydroxylation; aromatic

hydroxylation at positions 5, 6, 7, and 8 also occurs and acidic ring-opened metabolites are also formed. There is no evidence of glucuronic acid conjugation in man. The extent of 4-hydroxylation of debrisoquine is genetically determined. About 75% of a dose is excreted in the urine in 24 hours. Excretion of unchanged drug ranges from 8 to 80% of a dose. About 90% of the population are extensive metabolisers of debrisoquine and, in these subjects, about 10 to 40% of a dose is excreted as 4-hydroxydebrisoquine; the remaining 10% are poor metabolisers and excrete less than 2% as the 4-hydroxy metabolite. Acidic ring-opened metabolites account for up to 15% of a dose and the 5-, 6-, 7-, and 8-hydroxy metabolites for about 7%. About 12% of a dose is eliminated in the faeces.

THERAPEUTIC CONCENTRATION.Following a single oral dose of 20 mg to 3 subjects, peak plasma concentrations of 0.010, 0.013, and 0.024 $\mu\text{g/ml}$ of debrisoquine were reported at 1.5 to 3.5 hours; peak concentrations of the 4-hydroxy metabolite averaging 0.035 $\mu\text{g/ml}$ were attained in 1.5 to 2.5 hours. The 4-hydroxy metabolite was eliminated more rapidly than debrisoquine and was not detectable after 24 hours (J. H. Silas *et al.*, *Br. J. clin. Pharmacol.*, 1978, 5, 27–34).Maximum steady-state plasma concentrations of 0.015 to 0.18 $\mu\text{g/ml}$ (mean 0.08), and 0 to 0.05 $\mu\text{g/ml}$ (mean 0.02) for debrisoquine and 4-hydroxydebrisoquine respectively, were reported in 13 patients receiving daily oral doses of 40 mg (J. H. Silas *et al.*, *Br. med. J.*, 1977, 1, 422–425).**HALF-LIFE.** Plasma half-life, debrisoquine about 16 to 30 hours, 4-hydroxydebrisoquine about 10 hours.**DISTRIBUTION IN BLOOD.** Plasma: whole blood ratio, 0.45.**PROTEIN BINDING.** In plasma, about 25%.**Dose.** The equivalent of 10 to 120 mg of debrisoquine daily; up to 300 mg or more daily may be given.**Decamethonium Bromide**

Muscle Relaxant

Proprietary Name. Sincurine

 NN' -Decamethylenebis(trimethylammonium) dibromide $C_{16}H_{38}Br_2N_2 = 418.3$

CAS—156-74-1 (decamethonium); 541-22-0 (bromide)

A white, hygroscopic, crystalline powder. M.p. about 265°, with decomposition.

Freely **soluble** in water and ethanol; practically insoluble in ether.

Thin-layer Chromatography. *System TA*—Rf 00; *system TN*—Rf 56; *system TO*—Rf 16. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—227 nm ($A_1^1 = 584$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1627, 910, 965, 1030, 1136, 1063 (KBr disk).

Dose. Initially 2 to 2.5 mg by intravenous injection.

Decoquinat

Coccidiostat (Veterinary)

Proprietary Name. Deccox

Ethyl 6-decyloxy-7-ethoxy-4-hydroxyquinoline-3-carboxylate

$C_{24}H_{35}NO_5 = 417.5$

CAS—18507-89-6

A cream to buff-coloured microcrystalline powder. M.p. about 242°.

Practically **insoluble** in water and ethanol; slightly soluble in chloroform and ether; soluble in acetone.

Colour Tests. Liebermann's Test—orange (slow); Mandelin's Test—red-brown.

Gas Chromatography. *System GA*—not eluted.

Ultraviolet Spectrum. Methanolic acid—265 nm ($A_1^1 = 1000$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1695, 1613, 1497, 1263, 1205, 1558 (KBr disk).

Dehydroemetine

Antiprotozoal

2,3-Didehydro-6',7',10,11-tetramethoxyemetan

$C_{29}H_{38}N_2O_4 = 478.6$

CAS—4914-30-1

Dehydroemetine Hydrochloride

Proprietary Name. Dametine

$C_{29}H_{38}N_2O_4 \cdot 2HCl = 551.6$

CAS—2228-39-9

A white crystalline powder.

Soluble 1 in 30 of water.

Colour Test. Marquis Test—orange.

Thin-layer Chromatography. *System TA*—Rf 43; *system TB*—Rf 06; *system TC*—Rf 21. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—230 nm ($A_1^1 = 290$ a), 283 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1121, 1222, 1508, 1252, 1205, 1022 (dehydroemetine hydrochloride, KBr disk).

Mass Spectrum. Principal peaks at m/z 192, 193, 287, 176, 191, 286, 270, 285.

Dose. 60 to 180 mg of dehydroemetine hydrochloride daily, intramuscularly.

Demecarium Bromide

Anticholinesterase

Proprietary Names. Humorsol; Tosmilen(e).

3,3'-[*NN'*-Decamethylenebis(methylcarbamoyloxy)]bis(*NNN*-trimethylanilinium) dibromide

$C_{32}H_{52}Br_2N_4O_4 = 716.6$

CAS—56-94-0

A white or slightly yellow, slightly hygroscopic, crystalline powder. M.p. 163° to 168°, with decomposition.

Freely **soluble** in water and ethanol; soluble in ether.

Thin-layer Chromatography. *System TA*—Rf 00. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—259 nm ($A_1^1 = 14$ b), 265 nm. No alkaline shift.

Infra-red Spectrum. Principal peaks at wavenumbers 1724, 1216, 1149, 1178, 1124, 943 (KBr disk).

Use. As a 0.25 to 0.5% ophthalmic solution.

Demeclocycline

Antibiotic

Synonyms. Demethylchlortetracycline; DMCT.

Proprietary Name. Ledermycin (drops and syrup)

7-Chloro-6-demethyltetracycline

$C_{21}H_{21}ClN_2O_8 = 464.9$

CAS—127-33-3

A yellow crystalline powder.

Sparingly **soluble** in water; soluble 1 in 200 of ethanol and 1 in 40 of methanol; soluble in dilute hydrochloric acid and in solutions of alkali hydroxides and carbonates.

Demeclocycline Hydrochloride

Proprietary Names. Declomycin; Ledermycin(e) (capsules and tablets). It is an ingredient of Declostatin and Deteclo.

$C_{21}H_{21}ClN_2O_8 \cdot HCl = 501.3$

CAS—64-73-3

A yellow, amphoteric, crystalline powder.

Soluble 1 in 30 to 1 in 60 of water, 1 in 45 to 1 in 200 of ethanol, and 1 in 50 of methanol; practically insoluble in chloroform and ether; soluble in aqueous solutions of alkali hydroxides and carbonates.

Dissociation Constant. pK_a 3.3, 7.2, 9.3 (25°).

Partition Coefficient. Log *P* (octanol/pH 7.5), -1.3.

Colour Tests. Benedict's Reagent—red; Formaldehyde-Sulphuric Acid—orange → brown-red; Mandelin's Test—violet-brown; Marquis Test—yellow → green; Nessler's Reagent—brown; Sulphuric Acid—brown-blue.

Thin-layer Chromatography. *System TA*—*Rf* 0.5, streaking. (Location under ultraviolet light, orange fluorescence; *acidified potassium permanganate solution*, positive.)

Ultraviolet Spectrum. Aqueous acid—268 nm ($A_1^1 = 398$ a); aqueous alkali—241 nm ($A_1^1 = 364$ b), 276 nm ($A_1^1 = 304$ b), 388 nm ($A_1^1 = 385$ b).

Infra-red Spectrum. Principal peaks at wavenumbers 1616, 1573, 1660, 1190, 1298, 1315 (KBr disk).

Disposition in the Body. Readily absorbed after oral administration and slowly excreted in the urine.

HALF-LIFE. Plasma half-life, about 10 to 15 hours.

PROTEIN BINDING. In plasma, 40 to 90%.

Dose. Usually 600 mg of demeclocycline hydrochloride daily; up to 1.2 g daily has been given.

Demeton-S

Pesticide

Synonyms. Isosystox; Mercaptofos Teolovy.

OO-Diethyl *S*-2-ethylthioethyl phosphorothioate

$C_8H_{19}O_3PS_2 = 258.3$

CAS—126-75-0

A colourless oil.

Soluble 1 in 500 of water; soluble in most organic solvents.

Demeton-S-methyl

Synonyms. Methyl-mercaptofos Teolovy; Metaisostox.

Note. The name Demeton-methyl used to be applied to a mixture of demeton-S-methyl and demeton-O-methyl but this mixture has been replaced by demeton-S-methyl.

Proprietary Names. Azotox; Demetox; DSM; Duratox; Metasystox 55.

$C_6H_{15}O_3PS_2 = 230.3$

CAS—919-86-8

A pale yellow oil of low viscosity. In solution or upon storage, demeton-S-methyl is oxidised to the sulfoxide and the sulphone. Refractive index 1.5065.

Soluble 1 in 300 of water; soluble in most organic solvents.

Colour Tests. Palladium Chloride—brown-orange; Phosphorus Test—yellow.

Gas Chromatography. Demeton-S-methyl: *system GA*—*RI* 1628; *system GK*—retention time 0.70 relative to caffeine.

Infra-red Spectrum. Principal peaks at wavenumbers 1020, 1250, 775, 793, 826, 1190 (demeton-S-methyl).

Mass Spectrum. Principal peaks at *m/z* 88, 60, 109, 142, 79, 47, 111, 61 (demeton-S-methyl).

Disposition in the Body. Demeton-S and demeton-S-methyl are very readily absorbed by all routes and have a particularly high toxicity following percutaneous absorption. They are rapidly hydrolysed in the tissues to the corresponding sulfoxide and sulphone.

TOXICITY. Demeton-S and demeton-S-methyl exert a direct inhibitory action on cholinesterase. The estimated minimum lethal dose is 5 g but exposure to 300 mg daily may be dangerous.

In a fatality due to the ingestion of demeton-S-methyl, the following postmortem tissue concentrations were reported: blood 10 µg/ml, bile 58 µg/ml, kidney 5 µg/g, liver 17 µg/g, urine 121 µg/ml (R. A. Hall and E. D. Carson, *Bull. int. Ass. forens. Toxicol.*, 1970, 7(3), 6).

Demoxepam

Tranquilliser

Synonym. Chlordiazepoxide Lactam

7-Chloro-1,3-dihydro-5-phenyl-2*H*-1,4-benzodiazepin-2-one 4-oxide

$C_{15}H_{11}ClN_2O_2 = 286.7$

CAS—963-39-3

A white crystalline powder.

Soluble in chloroform.

Dissociation Constant. pK_a 4.5, 10.6.

Partition Coefficient. Log P (octanol/pH 7.4), 1.5.

Colour Test. Formaldehyde-Sulphuric Acid—orange.

Thin-layer Chromatography. System *TA*—Rf 63; system *TB*—Rf 00; system *TC*—Rf 35; system *TD*—Rf 15; system *TE*—Rf 44; system *TF*—Rf 22. (Acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive.)

Gas Chromatography. System *GA*—demoxepam RI 2529, oxazepam RI 2336; system *GG*—demoxepam RI 3043, oxazepam RI 2803.

High Pressure Liquid Chromatography. System *HI*—demoxepam k' 2.42, oxazepam k' 4.62; system *HK*—demoxepam k' 0.03, oxazepam k' 0.73.

Ultraviolet Spectrum. Aqueous acid—237 nm, 305 nm; aqueous alkali—243 nm, 255 nm, 310 nm; methanol—236 nm ($A_1^1 = 1340$ b), 310 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1678, 690, 1240, 1265, 755, 717.

Mass Spectrum. Principal peaks at m/z 285, 286, 269, 287, 241, 242, 77, 270.

Quantification. SPECTROFLUORIMETRY. In plasma: demoxepam and chlorthalidoxepoxide, sensitivity 250 ng/ml—B. A. Koechlin and L. D'Arconte, *Analyt. Biochem.*, 1963, 5, 195–207.

GAS CHROMATOGRAPHY. In serum: demoxepam and chlorthalidoxepoxide, ECD—S. R. Sun and D. J. Hoffman, *J. pharm. Sci.*, 1978, 67, 1647–1648.

Disposition in the Body. Well absorbed after oral administration. About 10% of a dose is excreted in the urine in 24 hours and about 60% in 7 days, including about 27% as unchanged demoxepam and about 5% as conjugated oxazepam. Other urinary metabolites include the 5-(4-hydroxyphenyl) and 9-hydroxy derivatives. Approximately 15% of the dose is eliminated in the faeces in 7 days with about 2% as desmethyldiazepam.

Demoxepam is a metabolite of chlorthalidoxepoxide.

THERAPEUTIC CONCENTRATION.

Following a single oral dose of 20 mg of demoxepam given to 6 subjects, peak plasma concentrations of 0.50 to 0.74 $\mu\text{g/ml}$ (mean 0.6) were attained in 2 to 8 hours (M. A. Schwartz *et al.*, *J. pharm. Sci.*, 1971, 60, 1500–1503).

HALF-LIFE. Plasma half-life, 14 to 95 hours (mean 40).

Denatonium Benzoate

Alcohol Denaturant

Proprietary Name. Bitrex

Benzyl-diethyl(2,6-xylylcarbamoylmethyl)ammonium benzoate

$\text{C}_{28}\text{H}_{34}\text{N}_2\text{O}_3 = 446.6$

CAS—3734-33-6

A white crystalline powder. M.p. 166° to 170° .

Soluble in water; soluble 1 in about 2 of ethanol and 1 in about 3 of chloroform; very slightly soluble in ether.

Colour Test. Mandelin's Test—violet.

Thin-layer Chromatography. System *TA*—Rf 10. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Aqueous acid—263 nm ($A_1^1 = 36$ b), 269 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1550, 1596, 1680, 719, 704, 757.

Deoxycortone

Corticosteroid

Synonyms. Decortone; Deoxycorticosterone; Desoxycorticosterone; Desoxycortone; 21-Hydroxyprogesterone.

21-Hydroxypregn-4-ene-3,20-dione

$\text{C}_{21}\text{H}_{30}\text{O}_3 = 330.5$

CAS—64-85-7

Crystals. M.p. 141° to 142°.

Freely **soluble** in ethanol and acetone.

Deoxycortone Acetate

Proprietary Names. Cortiron; Doca; Percorten; Syncortyl. It is an ingredient of Plex-Hormone.

$C_{23}H_{32}O_4 = 372.5$

CAS—56-47-3

Colourless crystals or white or creamy-white crystalline powder. M.p. 155° to 161°.

Practically **insoluble** in water; soluble 1 in 50 of ethanol, 1 in 30 of acetone, 1 in 1.5 of chloroform, and 1 in 170 of ether.

Deoxycortone Pivalate

Synonyms. Deoxycortone Trimethylacetate; Desoxycorticosterone Pivalate.

Proprietary Name. Percorten M

$C_{26}H_{38}O_4 = 414.6$

CAS—808-48-0

A white or creamy-white crystalline powder. M.p. 198° to 206°. A solution in dioxan is dextrorotatory.

Practically **insoluble** in water; soluble 1 in 350 to 1 in 500 of ethanol, 1 in 3 of chloroform, and 1 in 60 of dioxan; slightly soluble in ether.

Colour Tests. Antimony Pentachloride—orange; Naphthol-Sulphuric Acid—orange-red/blue-black; Sulphuric Acid—yellow (green-yellow fluorescence under ultraviolet light).

Thin-layer Chromatography. Deoxycortone acetate: *system TP*—Rf 86; *system TQ*—Rf 52; *system TR*—Rf 98; *system TS*—Rf 95. (DPST solution.)

Ultraviolet Spectrum. Deoxycortone acetate: ethanol—240 nm ($A_1^1 = 445$ a).

Infra-red Spectrum. Principal peaks at wavenumbers 1242, 1667, 1744, 1718, 1203, 1610 (deoxycortone acetate, KBr disk).

Mass Spectrum. Principal peaks at m/z 43, 55, 299, 91, 147, 79, 253, 271 (deoxycortone acetate).

Dose. Usually 1 to 5 mg of deoxycortone acetate daily, intramuscularly; sublingual doses of 2 to 10 mg daily have also been given.

Deptropine

Antihistamine

Synonym. Dibenzheptropine

(1*R*,3*r*,5*S*)-3-(10,11-Dihydro-5*H*-dibenzo[*a,d*]cyclohepten-5-yloxy)tropane

$C_{23}H_{27}NO = 333.5$

CAS—604-51-3

Deptropine Citrate

Proprietary Names. Brontine. It is an ingredient of Brontisol.

$C_{23}H_{27}NO \cdot C_6H_5O_7 = 525.6$

CAS—2169-75-7

A white to off-white microcrystalline powder.

Very slightly **soluble** in water and ethanol; soluble 1 in 100 of methanol; practically insoluble in chloroform and ether.

Colour Tests. Mandelin's Test—yellow; Marquis Test—yellow.

Thin-layer Chromatography. *System TA*—Rf 13; *system TB*—Rf 24; *system TC*—Rf 04. (Acidified potassium permanganate solution, positive.)

Gas Chromatography. *System GA*—RI 2615.

High Pressure Liquid Chromatography. *System HA*— k' 5.0 (tailing peak).

Ultraviolet Spectrum. Methanol—266 nm ($A_1^1 = 18.6$ b), 272 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1059, 1040, 751, 760, 738, 1114 (KBr disk).

Mass Spectrum. Principal peaks at m/z 83, 140, 82, 124, 43, 96, 97, 42.

Dose. 2 mg of deptropine citrate daily.

Dequalinium Chloride

Antibacterial/ Antifungal

Synonyms. Decalinium Chloride; Decaminum.

Proprietary Names. Dequadin; Dequavagyn; Labosept; Optipect Halstabletten; Phylletten; Sorot.

1,1'-Decamethylenebis(4-amino-2-methylquinolinium chloride)

$C_{30}H_{40}Cl_2N_4 = 527.6$

CAS—6707-58-0 (dequalinium); 522-51-0 (chloride)

A creamy-white powder. M.p. about 315°, with decomposition. Slightly **soluble** in water; soluble 1 in 30 of boiling water, 1 in 60 of methanol, and 1 in 200 of propylene glycol.

Dequalinium Acetate

$C_{34}H_{46}N_4O_4 = 574.8$

CAS—4028-98-2

A white or pinkish-buff, slightly hygroscopic powder. M.p. about 280°, with decomposition.

Soluble 1 in 2 of water and 1 in 12 of ethanol.

Colour Tests. Aromaticity (Method 2)—red/brown-violet; Liebermann's Test—yellow (→ orange at 100°).

Thin-layer Chromatography. System *TA*—Rf 03. (Acidified iodoplatinate solution, positive.)

Ultraviolet Spectrum. Water—240 nm ($A_1^1 = 812$ b), 326 nm ($A_1^1 = 469$ b), 335 nm ($A_1^1 = 406$ b); aqueous acid—241 nm, 330 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1605, 1660, 765, 1560, 1540, 1307 (KCl disk).

Dose. Lozenges containing 250 µg of dequalinium chloride are available.

Deserpidine

Antihypertensive

Synonyms. Canescine; 11-Demethoxyreserpine.

Proprietary Names. Harmony. It is an ingredient of Enduronyl.

Methyl 11 - demethoxy - 18 - O - (3,4,5 - trimethoxybenzoyl)-reserpate

$C_{32}H_{38}N_2O_8 = 578.7$

CAS—131-01-1

An alkaloid isolated from the root of *Rauwolfia canescens* (Apocynaceae).

Crystals. M.p. 230° to 234°, with decomposition.

Practically **insoluble** in water; soluble in hot ethanol and chloroform.

Colour Tests. Mandelin's Test—blue → green; Marquis Test—grey-green.

Thin-layer Chromatography. System *TA*—Rf 72; system *TB*—Rf 03; system *TC*—Rf 77. (Acidified iodoplatinate solution, positive.)

High Pressure Liquid Chromatography. System *HA*—k' 0.4.

Ultraviolet Spectrum. Aqueous acid—269 nm; aqueous alkali—275 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1225, 1127, 1715, 1100, 1184, 1590 (KBr disk).

Mass Spectrum. Principal peaks at m/z 578, 195, 577, 367, 351, 579, 366, 365.

Dose. 0.25 to 1 mg daily.

Desferrioxamine

Chelating Agent

Synonyms. Deferoxamine; DFM; DFOM.

30-Amino-3,14,25-trihydroxy-3,9,14,20,25-penta-azatriacon-tane-2,10,13,21,24-pentaone

$C_{25}H_{48}N_6O_8 = 560.7$

CAS—70-51-9

Desferrioxamine Mesylate

Synonyms. Deferoxamine Mesylate; Desferrioxamine B Mesylate; Desferrioxamine Methanesulphonate.

Proprietary Name. Desferal

$C_{25}H_{48}N_6O_8 \cdot \text{CH}_3\text{SO}_3\text{H} = 656.8$

CAS—138-14-7

A white to cream-coloured powder.

Soluble 1 in 5 of water and 1 in 20 of ethanol; practically insoluble in dehydrated alcohol, chloroform, and ether.

Colour Test. Mandelin's Test—blue → violet.

Thin-layer Chromatography. *System TA*—Rf 08, streaking. (Acidified potassium permanganate solution, positive.)

Ultraviolet Spectrum. No significant absorption, 230 to 360 nm.

Infra-red Spectrum. Principal peaks at wavenumbers 1628, 1195, 1562, 1265, 1149, 1041 (KBr disk).

Disposition in the Body. Poorly absorbed after oral administration. It specifically chelates ferric iron to an octahedral complex, ferrioxamine, which is readily excreted in the urine. Theoretically, 100 mg of desferrioxamine can chelate approximately 8.5 mg of iron. About 13 to 65% of a ^{59}Fe -labelled dose is excreted in the urine in 24 hours.

Dose. In acute iron poisoning: 5 g of desferrioxamine mesylate by mouth, with 2 g intramuscularly, and up to 15 mg/kg/hour by intravenous infusion.

Desipramine
